It may be proper to explain some circumstances respecting the *formula* given in the above prescription. The ℞ with which it commences signifies *recipe* or *take;* and is prefixed to all medical receipts. Then follow the several ingredients of which the medicine is to be composed, with the quantities of each. These quantities are usually marked by peculiar characters or symbols, and the numbers employed are usually the Roman numerals. After the ingredients have been enumerated, and their quantities specified, there follows the title of the medicine, as *Potio* in the present instance, signifying *potion* or *purging draught*, with M.f. prefixed to it, which stand for *misce fiat*, or *misce ut fiat*, mix to make; and lastly, the direction how the medicine is to be taken or administered, *summo mane sumenda*, to be taken early in the morning. The ingredients of which a formula is composed have been, by writers on medical prescriptions, arranged under four heads: 1. The *basis* of the formula, which in the present instance is the rhubarb, constituting the principal ingredient, on whose action, modified where necessary, the chief success of the medicine, in fulfilling the required indication, is to depend. 2. The *adjuvant* or auxiliary, added to the basis, for the purpose of increasing its power, expediting its action, or rendering it more easily soluble in the juices of the stomach; in the above formula the *tartrate of potash* is the principal adjuvant. 3. The *corrector*, added to the basis when we wish to moderate or delay its action, to correct some unpleasant or injurious property of it, such as its odour, taste, acrimony, &c., or to prevent it from acting on the body in a different manner from that which the indication requires: thus, in the present formula, the warm *tincture of senna* is added, rather to correct the griping quality of the rhubarb, than to increase its action, and the *syrup of roses* to correct the unpleasant taste of the medicine; and the *essential oil* in the pepperment-water contributes to both these purposes: these, therefore, are to be considered as the correctors. 4. The *constituent*, or that ingredient which serves to reduce the rest into the form which is considered as most convenient for the exhibition of the medicine; in the present case the *peppermint-water* is the constituent, serving to reduce the medicine to the form of a potion or draught.

Medical *formulæ* are either *officinal* or *extemporaneous;* the former being such as are directed by authority of some public medical college to be kept in the shops of apothecaries, and the preparation of which is described in their *pharmacopœias* or dispensatories; the latter such as are prescribed by the physician or surgeon, as occasion may require.

PRESCRIPTION, in English law, "is when a man claimeth any thing for that he, his ancestors or predecessors, or they whose estate he hath, have had or used anything all the time whereof no memory is to the contrary." (*T. de la Ley.*) This definition appears to be sufficiently definite and comprehensive. There have been various attempts at defining prescription, and few of them have ended in entire success. According to a passage in Littelton, prescription is made essential to custom. He says, "No custome is to bee allowed, but such custome as hath been used by title of prescription; that is to say, from time out of mind. But divers opinions have been of time out of mind, &c., and of title of prescription, which is all one in the law." There is another claim, however, to which the term prescription is very frequently applied, and which resembles custom, in being endowed with the inseparable incidents of time and of usage, which is another essential to custom. Yet this claim differs from custom in the mode of pleading adopted in it, which serves to distinguish the difference of the right. The word prescription is given to this claim, because the plaintiff or defendant making it "prescribeth that," &c., going on to state the nature of his claim. The following example of such a prescription is taken from Coke upon Littelton:—"I. S. seised of the manor of D. in fee *prescribeth* thus: That I. S. his ancestors, and all whose estate he hath in the sayd manor, had and used to have common of pasture time out of mind in such a place, &c., being the land of some other, &c., as pertaining to the same manor." It accordingly follows that the claim by prescription is properly a claim of a determinate person; that by custom, as opposed to prescription, belongs and applies to a particular place, belongs and applies to many, nay, to an indefinite number of persons, such as to the inhabitants of an entire parish. From the first definition, it appears that prescription may belong to a man as the heir of his ancestors, or to a corporation as the representatives of their predecessors, or it may be the claim of one who holds a situation in which there is perpetual succession, or by a person in virtue of an estate which he holds.

It seems to form an essential element in prescription, that the use of the thing claimed should have been time out of mind continuous and peaceable. As to the signification of the expression "time out of mind," it means that there must be no evidence of the non-usage of the claim subsequent to the first year of legal memory; that is, after the beginning of the reign of the first Richard. In order to substantiate the prescription, there must also be evidence of repeated usage; but where the evidence fails to show the beginning of the enjoyment, twenty years has been considered sufficient proof. Prescription is said to be founded on the assumption of an original grant that has been long lost. Thus Blackstone, in speaking of the erection of corporations, has the following passage:—"Another method of implication, whereby the queen's consent is presumed, is, as to all corporations, by prescription; such as the city of London, and many others, which have existed as corporations time whereof the memory of man runneth not to the contrary, and therefore are looked upon in law to be well created. For though the members thereof can show no legal charter of incorporation, yet, in cases of such high antiquity, the law presumes that there once was one; and that, by the variety of accidents which a length of time may produce, the charter is lost or destroyed."

Some alterations as to prescription have been made by recent acts, limiting the time within which actions can be brought, or suits instituted, relating to real property. Such are the 3 and 4 Will. IV., c. 27; also 2 and 3 Will. IV., c. 100. The 2 and 3 Will. IV., c. 71, is entitled "An Act for Shortening the time of Prescription in certain Cases," and applies (§ 1) to "claims which may be lawfully made at the common law by custom, prescription, or grant, to any right of common, or other profit or benefit, to be taken from or upon any land, &c., except such matters and things as are therein specially provided for, and except tithes, rents, and services." Section 2 applies "to any way or other easement, or to any watercourse, or the use of any water;" and sect. 3 to the use of light. It is further enacted, that no claim to the things comprised within this statute, "shall, when such right, profit, or benefit (as is mentioned in sect. 1), shall have been actually taken and enjoyed by any person claiming right thereto, without interruption, for the full period of thirty years, be defeated or destroyed, by showing only that such right, profit, or benefit was first taken or enjoyed at any time prior to such period of thirty years; but nevertheless such claim may be defeated in any other way by which the same is now liable to be defeated; and where such right, profit, or benefit shall have been so taken and enjoyed, as aforesaid, for the full period of sixty years, the right thereto shall be deemed absolute and indefeasible, unless it shall appear that the same was taken and enjoyed by some consent or agreement, expressly made or given for that purpose by deed or writing." The terms of twenty and forty years are fixed respectively, instead of thirty and sixty, as mentioned in the first section. The eighth section enacts, "that when any land or water upon, over, or from which any such way, or other convenient watercourse, or use of water, shall have been enjoyed or derived, hath been or shall be held under any term of life, or any term of years exceeding three years from the granting therof, the time of the enjoyment of any such way, or other matter as therein last mentioned, during the continuance of such term, shall be excluded in the computation of the said period of forty years, in case the claim shall, within three years next after the end, or sooner determination of such term, be resisted by any person entitled to any reversion expectant on the determination thereof."

Prescription, in Scotch law, has a much wider operation than in either the civil law or the law of England, supplying the place, as it does, of the statute of limitations in the latter system. In Scots law, and according to the long prescription, titles may be had to heritable property through a series of consecutive titles, extending over a period of forty years. But this positive prescription must be accompanied by negative prescription, to afford it free operation. By negative prescription is meant the absence of any effort on the part of one who may have a competing title to put his claim in force. This negative prescription will of itself destroy a claim by one party in cases where it cannot be directly said there is relative possession on the part of the other, independently of the existence of any positive prescription. The act creating this prescription says generally regarding obligations, "the party to whom the obligation is made that has interest therein, shall follow the said obligation within the space of forty years, and take document thereupon. And if he does not, it shall be prescribed, and be of no avail, the said forty years being run, and unpursued by the party." Prescription is counted from the day when fulfilment of the obligation became exigible, and it is effectual in all cases of debt, bonds, provisions in marriage-contracts, &c. Prescription can only be interrupted by the act of the person against whose claim it is running. Suspension of prescription takes place during minority; and so if the person having a claim have been twenty years a minor, he cannot lose his claim by negative prescription in less than sixty years. A similar suspension takes place in all cases where the creditor is physically disabled from acting. The short prescription, or, more properly speaking, limitation, is an exclusion on the ordinary means of proving the obligation. The triennial prescription, or the limitation of the existence of an obligation to three years, runs on most debts contracted in ordinary business without a written obligation. A prescription of five years takes place in all bargains concerning moveables or sums of money which may be proved by witnesses, such as contracts of sale, letting and hiring, &c. Holograph writings, or those of which the whole is written by the granter, if not attested by witnesses, prescribe in twenty years. Actions on the ground of the transactions between tutor and curator, on either side, prescribe in ten years after the expiration of the guardianship; and the operation of certain cautionary obligations is limited to seven years; while bills of exchange and promissory-notes prescribe as items of debt in six years. (Hill Burton's *Manual of Scots Law.*)

PRESENT TENSE, in grammar, the first tense of a verb, expressing present time, or that something is now performing; as *I write*, or *I am writing*.

PRESENTATION to a living in the English Church may be performed by any patron to whom the advowson of the church belongs, by offering his clerk to the bishop of the diocese to be instituted. The bishop, however, has the power of refusing the said clerk: this on many accounts, as,—1. If the patron be excommunicated, and remain in contempt forty days; or 2. If the clerk be unfit, which unfitness is of several kinds: first, with regard to his person, for he may be an outlaw, an excommunicate, an alien, under age, or the like; next, with respect to his faith or morals,—as for any particular heresy, or vice that is *malum in se;* or, finally, the clerk may be unfit to discharge the duties of the pastoral office by reason of his want of learning. If the bishop, however, have no objections, then the care of the souls of the parish is committed to the charge of the clerk, who enters on the parsonage-house and glebe, and takes the tithes.

PRESIDENT, Præses, is an officer created or elected to preside over a company or assembly, and is so called in contradistinction to the other members, who are termed *residents.*

Lord President of the Council is a great officer of the crown, who has precedence next after the lord chancellor and lord treasurer. The lord president is as ancient as the time of King John, when he was styled *consiliarius capitalis.* His office is to attend on the king, to propose business at the council-table, and to report to the king the several matters transacted there.

PRESS. See Printing, and Liberty of the Press.

PRESSBURG (Hung. *Posony*), a town of Hungary, at one time the capital of that kingdom, as it is still of the county of Pressburg, stands in a beautiful country, amidst vine-covered hills, near the foot of the Little Carpathians, on the left bank of the Danube, here crossed by a bridge of boats, 34 miles below Vienna. It is built on sloping ground, and has much the appearance of a quiet German country town, with few Hungarian characteristics. The most conspicuous object is a large brick castle, of which only the walls now remain, as it was destroyed by fire in 1811. The ruins, which stand on a hill, command a fine view of the broad plains of Hungary and the windings of the Danube. The cathedral, in which the kings of Hungary were crowned, is an ancient Gothic building of the eleventh century. It contains many trophies gained from the Turks, and an equestrian statue in lead of St Martin, which is a masterpiece of Donner. The Landhaus, in which the meetings of the Diet were held, is a very plain building; and the chambers are simple rooms with green baize tables, round which the members sat in their splendid Hungarian costume. Pressburg contains also an ancient town-hall; numerous churches, chapels, and convents; an archiepiscopal palace; archbishop's summer residence; and several palaces of the nobility. Near the end of the bridge there is an artificial hill, 12 or 14 feet high, surrounded by a railing. It is called the Königsberg; because here each king of Hungary after his coronation used to proceed on horseback, and from the top of the mound waved the sword of St Stephen towards the four points of the compass, as a sign that he would defend the country from all enemies. The educational establishments of Pressburg comprise a royal academy, with faculties of law and medicine; a Roman Catholic theological seminary and upper school; an evangelical college for philosophy and theology; and several elementary schools. The town has also a public library and several hospitals. Silk and cotton goods, tobacco, nitre, and leather, are among the chief manufactures of Pressburg; and an active trade is carried on, chiefly in rural produce. The town is of great antiquity, and is said to have existed even before the conquest of the country by the Romans. From 1547, when Buda was taken by the Turks, till 1784, it was the capital of Hungary; but in the latter year Joseph II. again made Buda the capital. In 1619 Pressburg was taken by Bethlen Gabor, but retaken in 1621 by the imperialists under Boucquoi. In 1805, after the battle of Austerlitz, a treaty was concluded here between France and Austria. Pop. (1851), exclusive of the military, 42,178.

PRESTEIGNE, a parliamentary borough and market-town of Wales, in the county of Radnor, on the borders of Hereford, in a fertile valley watered by the Lug, 6 miles E. by N. of Radnor, and 151 W.N.W. of London. The parish church is a large ancient building containing several curious monuments, and an altar-piece of tapestry. There are here also Wesleyan, Primitive Methodist, and Baptist churches, a free grammar school, a county-hall, and a jail. Large quantities of malt are made here; and there is some trade in timber. Pop. (1851) 1617.

PRESTER or PRESBYTER JOHN, was the name given by the Europeans of the middle ages to a dynasty of supposed eastern potentates. The following account is the history of this legend:—About the beginning of the eleventh century, it began to be reported in Christendom that a certain king beyond Persia and Armenia had been met by the spirit of a departed saint in a forest; that he had been overawed into becoming a true believer; and that he had ordered all his subjects, to the number of 200,000, to adopt the same faith. As time passed by, the report seemed to receive corroboration. Envoys pretending to come from the land in question arrived at Rome. Additional rumours, by what means nobody knew, found their way to the West. The manners and customs of this newly-Christianized people were said to retain many traces of the old patriarchal times. The chief was both priest and king, and was known on that account by the name of Prester or Presbyter John. His tribe lived a peaceful pastoral life, following their flocks through the desert, feeding upon flesh and milk, and being so destitute of corn and wine that they were unable in the prescribed manner to observe the fast-days, or to partake of the eucharist. Nor was the exquisite primitive simplicity of his kingdom unadorned by substantial wealth and majesty. Unbounded treasures were at his command; many neighbouring nations were his tributaries; and he swayed supremely with a sceptre of emerald.

Such pleasing reports as these continued to be greedily swallowed by the superstitious in Europe, until investigations commenced to be made. It then began to appear doubtful whether this happy land were not a mere Utopia, and whether this admirable Prester John were not a mere creature of the popular fancy. Carpini, a Franciscan friar who was sent by Pope Innocent IV. in 1246 on an embassy to the Mongols, failed to discover the celebrated nation of Christians. Not long afterwards another Franciscan, William de Rubruquis, who penetrated into Asia as far as Karakorum, could find none but a few Nestorians, who had even heard of the great priest-king. Equally unsuccessful were the Portuguese explorers who reached India by the way of the Cape of Good Hope about the end of the fifteenth century. After fruitlessly seeking for the Prester in Asia, they were fain to suppose, on few or no grounds, that they had found him in Africa in the person of an Abyssinian prince. The result of all these explorations was, that investigators ceased to inquire into the truth of the story of Prester John, and turned their attention to an explanation of its origin. The most plausible solution is that given by Mosheim in his *Church History*. He supposes that a certain Nestorian priest named John gained possession of a throne in Asiatic Tartary; that he still retained the name of Presbyter after his accession; and that the title of Prester John was inherited by his descendants, along with the throne, until his dynasty was extirpated by the mighty Tartar emperor Genghiskan.

PRESTO, in the Italian music, intimates to perform quickly; and hence *prestissimo* denotes extreme quickness.

PRESTON, a parliamentary and municipal borough, seaport, and market-town of England, in the county of Lancaster, on the N. bank of the Ribble, here crossed by three fine bridges, 19 miles S. of Lancaster, and 217 N.W. by N. of London. It is well built, for the most part of brick, on a rising ground about 120 feet above the river; and the principal streets, one of which, called Fishergate, is about a mile long, are broad and well paved. In the neighbourhood there are many villas, and some beautiful public walks. One of the latter, called Avenham Walk, on the top of the hill on which Preston is built, is much frequented, and has been well laid out by the corporation. There are in the town a spacious market-place, and many elegant terraces and squares. Among the public buildings are the guild-hall, a brick edifice with a turret and cupola, in the centre of the town; the court-house, built in 1826, in the Grecian style of architecture; the market-house, corn exchange, cloth-hall, custom-house, theatre, and assembly-rooms. Of the places of worship in Preston, ten belong to the Established Church. The parish church, rebuilt in 1770, has a lofty spire. Those of St Peter and St Paul, erected in 1824 and 1825, are both in the modern Gothic style; and Christ church is a fine specimen of pure Norman architecture. The Roman Catholics have four churches here, one of which is a building of great elegance. There are also places of worship belonging to Wesleyan Primitive, Episcopalian Primitive, and Associated Methodists; Baptists, Independents, Unitarians, Quakers, Swedenborgians, and Mormonites, to the number of twenty in all. One of the finest buildings in the town is a Grecian structure belonging to the Society for Diffusing Useful Knowledge, containing a library of 5000 volumes, and a valuable museum. The educational institutions comprise a free grammar school, founded in 1663, occupying a large stone edifice, and attended by 130 scholars in 1852; a blue-coat school, several national and infant schools, and a deaf-and-dumb institution. Preston has also a literary and philosophical society, with an elegant building of the Tudor style, a mechanics' institute, agricultural society, and three public libraries. There are, besides, nine alms-houses, a dispensary, infirmary, workhouse, and savings-bank. Public baths and wash-houses have been erected here by the corporation, and were opened in 1851. The town contains a borough prison and county penitentiary; while at Fulwood, 2 miles to the N.W., there are large barracks. Preston is chiefly important as a manufacturing and commercial town. Its staple manufacture at present is cotton, of which it is one of the principal seats in England. This branch of trade was introduced here in 1777, before which time the principal industry of the place was directed to the manufacture of linen, which is still carried on to a considerable extent. There are upwards of fifty mills for spinning and weaving cotton, worsted and flax mills, iron and brass foundries, tanneries, rope-works, malt-houses, and breweries. Fishery has been carried on for a long time in the Ribble, where salmon, eels, &c., are caught. The river has been, by dredging and other improvements, rendered navigable at spring tides for vessels of 300 tons burden up to the quays of the town, where extensive warehouses have been erected. Besides those derived from the navigation of the Ribble, Preston enjoys many advantages for commercial purposes in being connected, both by canals and railways, with the central and other parts of the country. The commerce of the town is considerable; corn, timber, and iron being the principal imports. On the 31st December 1857 there were registered at the port 114 sailing-vessels, tonnage 6253; and 3 steamers, tonnage 440. During that year there entered 295 sailing-vessels, tonnage 16,485; and 2 steamers, tonnage 298: and there cleared 517 sailing-vessels, tonnage 25,382,—all of these, except 11 sailing-vessels that entered from foreign ports, tonnage 1414, being engaged in the coasting trade. Besides weekly markets, several annual fairs are held at Preston; and there are races, which take place on the other side of the river. A celebration called the "Guilds" is held at Preston once every twenty years, generally in the end of August. It consists of a procession of the corporation and the various trades of the town, and is an occasion of great festivity. The borough is governed by a mayor, twelve aldermen, and thirty-six councillors. It returns two members to the House of Commons. The origin of Preston seems to date from the decay of Ribchester, which is now a mere village, 11 miles farther up the river; and the name *Priests-town* was probably given to it on account of its ecclesiastical edifices, some remains of which still exist. In 1323 it was taken and partly burned by the Scotch under Robert the Bruce. In the civil war Preston adhered to the royal cause, but was besieged and taken by the parliamentary forces. In 1715 the Jacobites took possession of the town, and erected barricades for its defence, but after a brave resistance were obliged to surrender. In January 1854 a strike of the workmen at Preston occurred, which lasted twenty-nine weeks, causing a great excitement and much distress among the work-people. Sir Richard Arkwright, the inventor of the spinning-jenny, was born at Preston in 1732. Pop. (1851) 69,542.

PRESTONPANS, a burgh of barony and seaport-town of Scotland, in the county of Haddington, on the S. shore of the Firth of Forth, 8 miles E. of Edinburgh. It is meanly and irregularly built, and contains a plain parish church, a Free church, a parish school, and an hospital. The manufacture of salt is carried on here; and there are potteries, a distillery, and a brewery. The people are also largely employed in the oyster fishery. Near the town was fought the battle of Prestonpans, in which the Pretender entirely defeated the forces of Sir John Cope, September 21, 1745. Pop. (1851) 1640.

PRESTWICK, or Priestwick, a burgh of barony of Scotland, in the county and 4 miles N.N.E. of Ayr. It is an old and decayed place, with a deserted church that serves as a sea-mark to ships in the Firth of Clyde, a cross, council-house, and prison. Pop. (1851) 1200.

PRETERITE. See Grammar.

PREVESA, a fortified town of European Turkey, in Albania, on the N. shore of the Gulf of Arta, 18 miles S.W.

of Arta, and 58 S.S.W. of Yanina. It has all the appearance of an oriental town, with its fantastically-carved mosque having a tall slender minaret. The streets are narrow and crooked, and the houses built chiefly of wood. There is a harbour, where some trade is carried on. Timber, tobacco, oil, wool, cotton, &c., are exported; and coffee, sugar, hardware, &c., are imported. Prevesa belonged to the Venetians from 1684 until the fall of that republic in 1797. It was then held by the French for a time, but was afterwards taken by the Turks. About 3 miles from the town are the ruins of the ancient Nicopolis. Pop. about 4000.

PRIAM, King of Troy, was the son of Laomedon and Strymo or Placia. His original name, *Podaras*, "the swift-footed," is said to have been changed into *Priamus* "the ransomed," from his having been ransomed by his sister Hesione, when he had fallen into the hands of Hercules. He is said to have been first married to Aisbe, by whom he became the father of Æsacus; but giving her up to Hyrtacus, he married Hecuba, by whom he had nineteen sons. He took no active part in the Trojan war, from his advanced age. Priam is said to have been killed by Pyrrhus, the son of Achilles, at the sacking of Troy by the Greeks (about 1184 B.C.)

PRIAPUS, according to some, the son of Dionysus and Aphrodite; according to others, the son of Dionysus and a Naiad, the son of Adonis and Aphrodite, the son of Hermes, and the son of Pan or a satyr. He is reported to have been born at Lampsacus on the Hellespont (whence the name *Hellespontiacus*), of extreme ugliness, and with unusually large genitals. He was worshipped as the promoter of fertility, both vegetable and animal. First-fruits were offered to him; milk, honey, and cakes; rams, asses, and fishes. He was represented in carved images, mostly in the form of *hermæ*, or of a head placed on a quadrangular pillar, painted red (whence *ruber* or *rubicundus* is applied to him by Ovid, *Fasti*, i. 415, vi. 319, 333), carrying fruit in his garment, and either a sickle or cornucopia in his hand.

PRICE, RICHARD, Fellow of the Royal Society of London and of the Academy of Sciences, New England, was born at Tynton in Glamorganshire on the 22d of February 1723. His father was a dissenting minister at Bridgend in that county, and died in 1739. At eight years of age he was placed under a Mr Simmons of Neath; and four years afterwards he was removed to Pentwyn, in Caermarthenshire, where he was placed under the Rev. Samuel Jones, whom he represented as a man of a very enlarged mind, and who first inspired him with liberal sentiments of religion. Having lived as long with him as with Mr Simmons, he was sent to Mr Griffith's academy at Talgarth in Breconshire. In 1740 he lost his mother, upon which he quitted the academy and proceeded to London. Here he was settled at the academy of which Mr Eames acted as the principal tutor, under the patronage of his uncle, the Rev. S. Price, who was for upwards of forty years co-pastor with Dr Watts. At the end of four years he left this academy, and resided with Mr Streatfield, of Stoke Newington, in the quality of domestic chaplain; whilst at the same time he regularly assisted Dr Chandler at the Old Jewry, and occasionally assisted others. Having lived with Mr Streatfield nearly thirteen years, he was induced to change his situation, and in the year 1757 married Miss Blundell of Leicestershire. He then settled at Hackney; but being shortly afterwards chosen minister at Newington Green, he lived there until the death of his wife, which took place in 1786, when he returned to Hackney. He was next chosen afternoon preacher at the meeting-house in Poor Jewry Street; but this he resigned on being elected pastor of the Gravel-pit Meeting, Hackney, and afternoon preacher at Newington Green. These he resigned with a farewell sermon in February 1791. Shortly afterwards he was attacked with a nervous fever, which reduced him to such a degree, that, worn out with agony and disease, he died on the 19th of April 1791. He bequeathed his property to a sister and two nephews.

In morals, Dr Price's principles were those of Cudworth and Clarke; and by many persons who have themselves adopted a very different theory, he is allowed to have defended these principles with greater ability than any other writer in the English language. In metaphysics he was a very great admirer of Plato, from whom he borrowed his doctrine concerning ideas. He was a firm believer in the immateriality of the soul; but with Dr Law, the learned bishop of Carlisle, he thought that from death to the resurrection of the body it remains in a dormant and quiescent state. He contended for its indivisibility, but maintained, at the same time, its extension; which, in the celebrated controversy with Dr Priestley, furnished the latter with some advantages which his own acuteness would never have obtained. In propagating his political principles, which were republican, he sometimes expressed himself with undue vehemence; and he was a zealous enemy to all religious establishments, which in his opinion encroach upon that liberty with which Christ has made us free. His faith respecting the Son of God was what has sometimes been called Low Arianism, and sometimes Semi-Arianism. From a very early age he claimed the privilege of thinking for himself on every subject. His father was a rigid Calvinist, and spared no pains to instil his own theological dogmas into the tender mind of his son; but young Richard would often start his doubts and difficulties, and sometimes incur the old man's displeasure by arguing against his favourite system with a perplexing ingenuity, and a solidity that could not easily be overturned. He had once the misfortune to be caught reading a volume of Clarke's sermons, which his father, in great wrath, snatched from him and threw into the fire. Perhaps he could not have taken a more effectual method to make the book a favourite, or to excite the young man's curiosity in regard to the other works of the same author; and it is by no means improbable but that this orthodox bigotry contributed more than any other circumstance to lay the foundation of his son's Arianism. An elegant notice of Price's moral system will be found in the SECOND PRELIMINARY DISSERTATION.

In 1763 or 1764 he was chosen a fellow of the Royal Society, and contributed largely to the transactions of that learned body; in 1769 he received from Aberdeen a diploma creating him Doctor of Divinity; and in 1783 the degree of Doctor of Laws was conferred upon him by the college of Yale in Connecticut. As in the year 1770 he refused an American degree which had been conveyed to him by Dr Franklin, his acceptance of one, thirteen years afterwards, can be attributed only to his extravagant attachment to a republican form of government.

To posterity his works will be his monument. They are,—*A Review of the Principal Questions and Difficulties in Morals*, 1758, 8vo; *Dissertations on Providence*, 1767, 8vo; *Observations on Reversionary Payments*, 1771, 8vo; *Appeal on the National Debt*, 1773, 8vo; *Observations on the Nature of Civil Liberty*, 1776; *On Materialism and Necessity, in a Correspondence between Dr Price and Dr Priestley*, 1779; *On Annuities, Assurances, and Population*, 1779, 8vo; *On the Population of England*, 1780; *On the Public Debts, Finances, and Loans*, 1783, 8vo; *On Reversionary Payments*, 1783, 2 vols.; *On the Importance of the American Revolution*, 1784; besides Sermons, and a variety of papers in the *Philosophical Transactions* on Astronomy and other philosophical subjects. (The *Memoirs of the Life of Richard Price, D.D.*, by Wm. Morgan, F.R.S., London, 1815, 8vo.)

PRICE, *Thomas*, an eminent Welshman, was born near Builth in Brecknockshire in 1788, and was educated for the church at the college of Brecknock. After settling down as vicar of Cwmdu in 1825, he appeared before the public as a man of great and many-sided activity. There was scarcely a gentlemanly accomplishment which he did not practise. He was an excellent swimmer, and an adept in archery and other athletic games. He carved in wood, modelled in wax and cork, etched with success, and played upon the Welsh harp. Nor did these elegant pastimes detain him from more elevated pursuits. His exertions for the honour of his nation were untiring. The Welsh *Eisteddfods*, or literary gatherings, received his thorough-going support. No less than fifteen Welsh periodicals were enriched by his contributions. Several essays on the Welsh literature proceeded from his pen. A Welsh history, *Hanes Cymru*, was published by him between 1836 and 1842. He continued, in fact, to be the great champion of his countrymen till his death in 1848. The most important of this author's works are contained in the *Literary Remains of the Rev. Thomas Price, with a Memoir of his Life*, by Jane Williams, Ysgafell, in 2 vols. 8vo, Llandovery, 1854–55.

PRICHARD, James Cowles, a great ethnologist, was born at Ross in Herefordshire on the 11th of February 1786, and was educated at London and Edinburgh for the medical profession. He was early led to devote his attention to ethnology by hearing objections brought against the Mosaic account of the origin of our race. His first thoughts on the subject were given in the thesis which he delivered on the occasion of taking his M.D. at Edinburgh. On his settlement at Bristol in 1810 as a physician, his inquiries assumed a more definite form. He addressed himself to the study in the most able and systematic manner. The most unwearied research, the most varied erudition, and the most sagacious deliberation, were brought to bear upon the subject. All the evidences in favour of a plurality of races were first either directly refuted or at least removed. The different kindreds, as described by many different authors, were next passed in review; their varieties of form, colour, language, and habits, were contrasted and compared; and the differences and resemblances were carefully ascertained. The differences were concluded to be chiefly the result of civilization; and the resemblances were adduced as a proof of the unity of the human race. The result of these investigations was a book published in 1813 under the title of *Researches into the Physical History of Man*. Nor did the enthusiastic ethnologist halt on the way of research upon which he had so successfully entered. It is true that during the next thirteen years his large and ever-open mind was occupied with an astonishing multiplicity of engagements. He maintained a large practice in Bristol and its neighbourhood, delivered lectures on physiology and medicine, and wrote treatises on fever, epilepsy, nervous diseases, and insanity. He also made himself an adept in German, Greek, and Hebrew, studied Egyptian mythology and history, and contributed various articles to periodicals. Yet in 1826, when the second edition of his *Researches* was published, it was found that his attention had been chiefly occupied in maturing and illustrating his ethnological opinions, and that much of his miscellaneous acquisitions had been employed for that purpose. Many improvements on the former edition were observable. A wider, and at the same time a more minute view had been taken of the families of mankind. Greater prominence had been given to language as a mark of affinity. Especially had the discovery been made that the Celtic tongues and the Sanscrit were sprung from the same stock. In fact, the book, by developing to its full extent the philological element in ethnology, had introduced a new era in the history of the science. Still the author with unwearied endeavour continued to correct and expand his views. An *Analysis of the Egyptian Mythology*, which he published in 1838, assisted him considerably in carrying out this purpose. His removal also to London in 1841 as inspector of the lunatic asylums was probably not without its effect. He did not cease his laborious investigations until he had completed the third edition of his work in five closely-printed volumes. The great task of Dr Prichard's life was now accomplished. He died in London in December 1848. At the time of his death Prichard was president of the Ethnological Society of London and a fellow of several learned societies both at home and abroad. The latest edition of his *Researches* is that in 5 vols. 8vo, London, 1851. An abstract of this work, which he published in 1843 under the title of *The Natural History of Man*, has gone through several editions. (See "A Biographical Sketch of Dr Prichard," by Thomas Hodgkin, M.D., in *The Edinburgh New Philosophical Journal*, vol. xlvii.)

PRIDEAUX, Humphry, a very learned clergyman of the Church of England, was born at Padstow in Cornwall in 1648. He studied three years at Westminster under Dr Busby, and was then removed to Christ Church, Oxford. Here, in 1676, he published his *Marmora Oxoniensia*. This introduced him to the Lord Chancellor Finch, afterwards Earl of Nottingham, who in 1679 presented him to the rectory of St Clement's, near Oxford, and in 1681 bestowed on him a prebend of Norwich. Some years afterwards he was engaged in a controversy with the Catholics at Norwich concerning the validity of the orders of the Church of England, which produced his book upon that subject. In 1688 he was installed in the archdeaconry of Suffolk, to which he was collated by Dr Lloyd, then bishop of Norwich. In 1691, upon the death of Dr Edward Pococke, the Hebrew professorship at Oxford, being vacant, was offered to Dr Prideaux; but he refused it. In 1697 he published his *Life of Mohammed*; and in 1702 he was installed dean of Norwich. Some time after his return to London he proceeded with his *Connection of the History of the Old and New Testament*, which he had commenced when he laid aside the design of writing the *History of Appropriations*. He died in 1724.

Prideaux, *John*, an eminent dignitary of the English Church, was born in 1578 at Stowford, an obscure hamlet near Ivy-Bridge in Devonshire. His rise in life began amid great embarrassments. While a poor village lad, he aspired to be clerk of the neighbouring parish of Ugborow, and was unsuccessful. The failure depressed his spirits very much, until a kind country lady sent him at her own expense to a school in the vicinity. There he unweariedly plodded on for some time, acquiring with great difficulty a small smattering of classical learning. A rustic-looking youth of eighteen, clad in breeches which were no better than leather, and had very little in their pockets, he then set out to travel on foot to the distant university of Oxford. On his arrival it was accepted by him as a great boon that he was allowed to become a student of Exeter College, on condition that he should also become a menial of Exeter kitchen. In spite of all these difficulties, however, Prideaux soon rose to eminence. His attainments recommended him to a probationer fellowship in 1602. The repute of his theological learning placed him in the rectorship in 1612. Nor in this important position did he fail to advance his reputation. His gentle and fatherly government won every heart. The students under his charge increased till they outnumbered those under any of the other rectors of the university. Some even came from abroad for the purpose of sitting at his feet. His fame was established; and no ecclesiastical preferment was beyond his reach. Several benefices, the office of regius professor of divinity, and the vice-chancellorship were conferred upon him. At length, in 1641, he was promoted by Charles I. to the see of Worcester. Bishop Prideaux, in the discharge of his high office, showed himself to be a fine specimen of the English clergyman of that period. Among his flock he was simple and gentle, a child in the affairs of this world, and a saint in the affairs of the next. In his study he was a good linguist, a profound theologian, and a very hammer of the heretics. And when the troubles of the civil war came, his spirit was not unequal to the trials of a martyr. In vain did the Puritans harass him, and sequestrate his estate for his adherence to the cause of the king. He continued true to the principles of his church, living upon the proceeds of his library for the rest of his life, and leaving at his death in 1650 no other legacy to his children but "pious poverty, God's blessing, and a father's prayers." The chief works of Bishop Prideaux are *Viginti Duæ Lectiones de Totidem Religionis Capitibus*, fol., Oxford, 1648; and *Fasciculus Controversiarum Theologicarum ad Juniorem*, 4to, Oxford, 1648. A list is given in Watt's *Bibliotheca Britannica.* (See Wood's *Athenæ Oxonienses.*)

PRIEGO, a town of Spain, Andalusia, in the province of Cordova, partly on a fertile plain, and partly on the slopes of the Sierra di Algarrinejo, 34 miles S.E. of Cordova. It is well built, and has broad, straight, and well-paved streets, adorned with several fountains, some of which are very elegant structures. Here are the ruins of a castle built by the Romans, and afterwards repaired and enlarged by the Moors. The public buildings include various churches, hospitals, and schools; a town-hall, theatre, flesh-market, &c. Oil and flour mills, tanneries, and potteries are the chief manufactories of the place. Priego was formerly a very wealthy town, on account of its numerous silk factories; but this branch of industry is not now extensively pursued here. This town was the birthplace of the sculptor Don Jose Alvarez. Pop. 13,464.

PRIESSNITZ, VINCENZ, the originator of the water-cure, was the son of a farmer, and was born at Gräfenberg in Austrian Silesia in 1799. He had not attained to manhood when circumstances occurred which were the means of leading him to his great discovery. The death of his father compelled him at an early age to take an active part in the management of the farm. One day as he was out in the fields driving a cart, the horse knocked him down, and the wheel passed over his side. The medical man who was called in found two of his ribs broken, and expressed a fear that he would be a cripple for life. It was then that Priessnitz resolved to try a new method of curative treatment. Having adjusted his broken ribs by expanding his chest to the utmost, he began to employ the regimen of drinking water plentifully, and applying wet cloths to the bruised parts of his body. His experiment proved successful. In a few days he was able to walk about, and at the end of a year he was performing his part in the labours of the farm. Similar cures were then applied to the maladies of his neighbours, and were attended with similar results. All the opposition of the medical faculty and of the enemies of innovation could not prevent the new science of hydropathy from gradually gaining a footing in the credit of the public. At length, in 1829, Priessnitz established cold baths at his native place, and became a hydropathist by profession. His efficiency in his new vocation was abundantly testified by the steadily-increasing popularity which he continued to gain. The Austrian government, so intolerant for the most part of all empirics, not only permitted him to practise, but even gave him their patronage. The number of patients who resorted to him annually from all parts of Europe increased in course of time to hundreds. The farm of Gräfenberg, on the slope of one of the Sudates, expanded into an extensive hospital of many houses, where invalids sought to regain health by means of sweating, pure air, exercise, plain diet, and lively conversation. The example spread; and before Priessnitz died in 1851, he had the gratification of seeing several hydropathic establishments in different European countries. (See Claridge's *Hydropathy*, London, 1842; and Selinger's *Vincenz Priessnitz eine Lebensbeschreibung*, 12mo, Vienna, 1852.)

PRIEST (Saxon, *preostor;* French, *prêtre;* Dutch, *priester;* Spanish, *presbutero;* all remotely derived from the Greek πρεσβύτερος, *an elder*, and immediately from the Latin *presbyter*), a person set apart for the performance of sacrifice, and other offices and ceremonies of religion. Before the promulgation of the law of Moses, the first-born of every family, the fathers, the princes, and the kings were priests. Thus Cain and Abel, Noah, Abraham, Melchizedec, Job, Isaac, and Jacob, offered themselves their own sacrifices. Amongst the Israelites, after their departure from Egypt, the priesthood was confined to one tribe, and it consisted of three orders,—the high priest, priests, and Levites. The priesthood was made hereditary in the family of Aaron, and the first-born of the oldest branch of that family, if he had no legal blemish, was always the high priest. This divine appointment was observed with considerable accuracy until the Jews fell under the dominion of the Romans, and had their faith corrupted by a false philosophy. Then, indeed, the high priesthood was sometimes set up to sale, and instead of continuing for life, as it ought to have done, it seems, from some passages in the New Testament, to have been nothing more than an annual office. There is sufficient reason to believe, however, that it was never disposed of except to some descendant of Aaron capable of filling it, if the older branches were extinct. In the time of David the inferior priests were divided into twenty-four companies, who were required to serve in rotation, each company by itself, for a week. The order in which the several courses were to serve was determined by lot; and each course was, in all succeeding ages, called by the name of its original chiefs.

All nations have had their priests. The pagans had priests of Jupiter, Mars, Bacchus, Hercules, Osiris, Isis, and other divinities; and some deities had also priestesses. The Mohammedans have priests of different orders called *scheiks* and *muftis;* and the Indians and Chinese have their Brahmins and Bonzes.

It has been very much disputed whether, in the Christian church, there be any such officer as a priest (ἱερεύς), in the proper sense of the word. The Church of Rome, which holds the propitiatory sacrifice of the mass, has of course her proper priesthood. In the Church of England the word priest is retained to denote the second order in her hierarchy, but with very different significations, according to the different opinions entertained of the Lord's Supper. Some few of her divines, of great learning and of undoubted Protestantism, maintain that the Lord's Supper is a commemorative and eucharistical sacrifice, and consider all who are authorized to administer that sacrament as, in the strictest sense, priests. Others hold the Lord's Supper to be a feast upon the sacrifice once offered on the cross; and these, too, must consider themselves as clothed with some kind of priesthood. Great numbers, however, of the English clergy, perhaps the majority, agree with the Church of Scotland in maintaining that the Lord's Supper is a rite of no other moral import than the mere commemoration of the death of Christ. These, therefore, cannot consider themselves as priests in the rigid sense of the word, but only as presbyters (πρεσβύτεροι), or, in other words, elders.

PRIESTLEY, JOSEPH, a distinguished natural philosopher and theologian, was born on the 24th of March 1773, at Field-head, in the parish of Bristall, in the West Riding of Yorkshire. His father was a cloth-manufacturer, and both his parents were respectable Calvinistic dissenters. A strong desire of reading was one of the first passions which this philosopher exhibited, and which probably induced his parents and friends to change their mind respecting his destination, and, instead of bringing him up as a tradesman, to qualify him for some learned profession. He acquired a knowledge of Hebrew, Greek, and Latin, in the school of an eminent teacher at Bartley; and, at the age of nineteen, he became a theological student in the academy of Daventry. When about the age of twenty-two, he was made choice of as assistant minister to the Independent congregation of Needham Market in Suffolk. Having resided at Needham for about three years, he received an invitation to become pastor of a small flock at Namptwitch in Cheshire, which he accepted. Here he opened a day school, in the management of which he displayed that turn for research, and that spirit of improvement, which were afterwards destined to form such prominent features in his character. His reputation as a man of extraordinary talents and diligent inquiry soon spread amongst his professional brethren; and when Dr Aitken was chosen to succeed the Reverend Dr Taylor as professor of divinity at Warrington, the vacant department of belles lettres was assigned to Mr Priestley.

His literary career may probably be said to have commenced at Warrington; and the extent, as well as the originality of his pursuits, were soon announced to the world by a variety of valuable publications. He composed *The Theory of Language and Universal Grammar*, 1762; on *Oratory and Criticism*, 1777; on *History and General Policy*, 1788; on *The Laws and Constitution of England*, 1772; an *Essay on a Course of Liberal Education for Civil and Active Life*, 1765; *Chart of Biography*, 1765; *Chart of History*, 1769. Much of his attention about this period was taken up with general politics, on which he delivered a number of lectures. Although it was reasonable to think that his time would be sufficiently occupied by his academical and literary employments, yet his unwearied activity and industry found means to accomplish the first great work in philosophy which laid a foundation for his future fame. Having long amused himself with an electrical machine, and felt himself interested in the progress of discovery in that branch of physics, he undertook a *History of Electricity*, with an account of its present state. This work made its first appearance at Warrington in the year 1767, and was so well received by the learned world that it went through a fifth edition, in quarto, in the year 1794. It is justly deemed a valuable performance, and its original experiments are allowed to be very ingenious. About the year 1768 he was chosen as pastor of a large and respectable congregation of Protestant dissenters at Leeds, which led him to give a very large share of his attention to theological subjects. His mind is said to have been from childhood strongly impressed with sentiments of piety and devotion; and although he changed most of those religious sentiments in which he had been instructed for such as he regarded more rational and consistent with truth, his piety and devotion never deserted him. He was at the head of the moderate Unitarians, whose leading tenet is the proper humanity of Christ; confining every species of religious worship and adoration to the one Supreme Being. Some, we believe, have charged him with a design to subvert the Christian religion; but, since zeal for Christianity, as a divine dispensation, and the most valuable of all gifts bestowed upon the human race, was his ruling passion, such an imputation cannot, in fairness, be admitted. His *History and Present State of Discoveries relating to Vision, Light, and Colours* appeared in 1772 in 2 volumes quarto. This is allowed to be a performance of great merit and lucid arrangement; but it did not bring him such a large share of popularity as his *History of Electricity*, because it is probable that he was scarcely qualified to explain the more abstruse parts of the science.

In the year 1770 he quitted the town of Leeds for a situation entirely different from that which he had held there. His philosophical writings, and the recommendation of Dr Price, had made him favourably known to the Earl of Shelburne, who held out to him such advantageous proposals for residing with him, that a regard for his family did not permit him to reject them. The domestic tuition of Lord Shelburne's sons having been previously committed to a man of merit, they received no instructions from Dr Priestley further than some courses of experimental philosophy. He also attended his lordship on a visit to Paris, where he had an opportunity of seeing some of the most celebrated men of science in that country, whom he astonished by asserting a firm belief in revealed religion, which had been presented to their minds in such colours that they thought no man of sense could hesitate in rejecting it as an idle fable. In the year 1775 he published his *Examination* of Dr Reid on the *Human Mind;* Dr Beattie on the *Nature and Immutability of Truth;* and Dr Oswald's *Appeal to Common Sense.* The design of this volume was to refute the doctrine of Common Sense said to be employed as the test of truth by the metaphysicians of Scotland. He never intentionally misrepresented either the arguments or the purposes of an opponent; but he measured the respect with which he treated him by that which he conceived for him in his own mind. In the year 1777 he published his disquisitions relating to *Matter and Spirit*, in which he gave a history of the philosophical doctrine respecting the soul, and openly supported the material system, which makes it homogeneous with the body. This subjected him to more odium than any of his other productions. As he materialized spirit, so he in some measure spiritualized matter, by assigning to it penetrability and several other subtle qualities. About the same period he became the champion of philosophical necessity; a doctrine not less obnoxious to many than the former, on account of its supposed effects on morality. So astonishing was the versatility of his mind, that he at the same time carried on that course of discovery concerning aëriform bodies which has rendered his name so illustrious amongst philosophical chemists. A second volume was published in 1775, and a third in 1777. Some of his most memorable discoveries were those of nitrous and dephlogisticated or pure air; of the restoration of vitiated air by vegetation, of the influence of light on vegetables, and of the effects of respiration on the blood.

The name of Priestley was by these means spread throughout all the countries of Europe, and honours were heaped upon him by nearly every scientific body. The term of his engagement with Lord Shelburne having expired, Dr Priestley found himself at liberty to choose a new situation, and retired with a pension for life of L.150 a year. He chose the vicinity of the populous town of Birmingham, which was then the residence of several men of science, such as Watt, Withering, Bolton, and Keir, whose names are well known to the public. Here he was invited to become pastor of a dissenting congregation, an offer which he accepted about the latter end of the year 1780. Soon after this appeared his Letters to Bishop Newcome *On the Duration of Christ's Ministry*, and his *History of the Corruptions of Christianity*, works which were afterwards followed by his *History of Early Opinions.* He displayed his attachment to freedom by his *Essay on the First Principles of Government*, and by an anonymous pamphlet on the *State of Public Liberty* in this country; and he evinced a warm interest in the cause of America at the time of its unfortunate quarrel with the mother country. On the 14th of July 1791 the celebration of the anniversary of the destruction of the Bastile, by a public dinner, at which Dr Priestley was not present, gave the signal for those riots which have brought lasting disgrace on the town of Birmingham, and in some degree on the national character. Amidst the conflagration of places of worship and of private dwellings, Dr Priestley was the great object of popular rage; his house, library, manuscripts, and apparatus, were given as a prey to the flames; he was hunted like a criminal, and experienced not only the furious outrages of a mob, but the most unhandsome treatment from some who ought to have supported the character of gentlemen and friends of good order. He now lay under a load of public odium and suspicion, and, besides, he was constantly harassed by the petty malignity of bigotry. It was not to be wondered at, therefore, that he looked for an asylum in a country to which he had always showed a friendly attachment, and which, he supposed, was in full possession of all the blessings of civil and religious liberty. In the year 1794 he took leave of his native country, and embarked for North America. He took up his residence at Northumberland, a town in the interior of the state of Pennsylvania, which he selected on account of the purchase of landed property in its neighbourhood; otherwise its remoteness from the seaports, its want of many of the comforts of life, and of all the helps to scientific pursuit, rendered it a peculiarly undesirable abode for one of Dr Priestley's habits and employments. The loss of his amiable wife, and of a most promising son, as well as repeated attacks of disease, severely tried the fortitude and resignation of this ill-fated philosopher. In America he was received with general respect, and the angry contests of party were not able wholly to deprive him of the esteem due to his character. He was heard as a preacher by some of the most distinguished members of Congress; and he was offered, but declined, the place of chemical professor at Philadelphia. It became his great object to enable himself, in his retirement in Northumberland, to renew that course of philosophical experiment, and especially that train of theological writing, which had occupied so many of the best years of his life. By numerous experiments on the constitution of airs, he became more and more fixed in his belief of the phlogistic theory, and in his opposition to the new French chemical system, of which he lived to be the only opponent of any celebrity. By the liberal contributions of his friends in England, he was enabled to commence the printing of two extensive works, upon which he was zealously bent, a *Church History* and an *Exposition of the Scriptures;* and during the progress of his final decline he unremittingly urged their completion. Since an illness which seized him at Philadelphia in the year 1801, he never recovered his former state of health. His complaint was constant indigestion, and a difficulty of swallowing food of any kind. But during this period of general debility he was busily employed in printing his *Church History*, in writing the first volume of his *Notes on the Scriptures*, and in making new and original experiments. During this period, likewise, he composed his pamphlet of *Jesus and Socrates Compared*, and reprinted his *Essays on Phlogiston.* From about the beginning of November 1803 till the middle of January 1804, his complaint grew more serious; yet, by judicious medical treatment and strict attention to diet, he, after a time, seemed to be, if not regaining strength, at least not getting worse; and his friends fondly hoped that his health would continue to improve as the season advanced. He, however, considered his life as very precarious. Even at this time, beside his miscellaneous reading, which was at times very extensive, he read through all the works which are quoted in his *Comparison of the different Systems of Grecian Philosophers with Christianity;* composed that work, and transcribed the whole of it in less than three months, thus leaving it ready for the press. In the last fortnight of January his fits of indigestion became more alarming than ever, his legs swelled, and his weakness increased. Within two days of his death he became so weak that he could walk but a little way, and that with great difficulty. He was fully sensible that he had not long to live, yet he talked with cheerfulness to all who called for him. He dwelt upon the peculiarly happy situation in which it had pleased the Divine Being to place him in life; the great advantage he had enjoyed in the acquaintance and friendship of some of the best and wisest men of the age in which he lived; and the satisfaction he derived from having led a useful as well as a happy life. On the 9th of February 1804 he breathed his last, so easily that those who were sitting close to him did not immediately perceive his death. He had put his hand to his face, which prevented them from observing his last moments.

In the constitution of Dr Priestley's mind, great ardour and vivacity of intellect were united with a mild and placid temper. With a zeal for the propagation of truth which nothing could subdue, he joined a calm patience and an unruffled serenity of temper which rendered him proof against disappointments. The rights of private judgment were rendered sacred to him by every principle of his understanding, and his heart would not have suffered him to injure his bitterest enemy. He was naturally disposed to be cheerful, and when his mind was not occupied with serious thoughts, he could unbend, with playful ease and negligence, in the private circle of friends; but in large and mixed companies he commonly spoke little. In the domestic relations of life he was uniformly kind and affectionate; his parental feelings were those of the tenderest and best of fathers; and not even malice itself could ever fix a stain upon his private conduct or impeach his integrity. The autobiography of Dr Priestley, written, as he informs us, during one of his summer excursions, concludes with the date, "Northumberland, March 24, 1795." It was published in America after his decease, with a continuation by his son, Joseph Priestley, and observations on his writings by Thomas Cooper and the Rev. William Christie. This has been incorporated by John Towell Rutt with the collected edition of Priestley's *Theological and Miscellaneous Works*, in 25 vols. 8vo, Hackney, 1817, containing, at p. 537 of the second volume, a complete list of his writings.

PRIMATE. See ARCHBISHOP.

PRIMATICCIO, FRANCESCO, a celebrated Italian artist, was born of a noble family at Bologna in 1490. His parents had intended him for the mercantile profession, but his own genius soon opened up for him a successful career in the province of the fine arts. Becoming a pupil of the great ornamental decorator Giulio Romano, who was then working at the palace Del T in Mantua, he speedily outstripped all his fellow-disciples in design and colouring. His growing excellence secured the patronage of the Duke Frederigo; and in 1531 he was sent by that potentate to France, with strong recommendations to King Francis. There he continued till his death in 1570, introducing Roman taste into France, and a new era into the history of French art. The efforts of his genius were especially expended on Fontainebleau. The walls of that palace were ornamented with frescoes and stucco-work, the halls were studded with ancient Roman marbles, and the gardens were adorned with bronze casts of some of the most famous sculptures of antiquity. It seemed, in fact, as if a miniature Rome had sprung up in the middle of France. (See Vasari's *Lives of the Painters*, &c., and Lanzi's *History of Painting.*)

PRIMING. See GUN-MAKING.

PRIMOGENITURE is that right or custom whereby a title of dignity or an estate in land comes to a person in virtue of his being the eldest male. Among the Jews, the eldest son or first-born had a double portion of his father's inheritance; but before the time of Moses there was no certain rule as to who should be considered the first-born Moses decreed the abolition of this custom, and ordained that the first-born in point of time should be recognised. Among the Greeks, and especially among the Athenians, Primogeniture.

the custom of primogeniture seems even to have been more severe towards females than among the Jews. If the father died without heirs-male of his body, and without a will, the nearest kinsman on the father's side was entitled to claim the estate, to the exclusion of any daughters whom he had left. If he had made a will, it should have bequeathed his estates to parties bound to marry his daughters. The Mohammedans held that females should inherit a certain portion of whatever their fathers might leave, allowing the males a double portion. Among the Romans a somewhat different policy seems to have prevailed; at all events, it was not till the time of Justinian that daughters were placed exactly on the same footing as sons with respect to the succession to intestate property. The Germanic nations generally, with the single exception of the Visigoths, gave a decided preference to heirs-male in regard especially to the succession to land. Females were occasionally excluded from succession to the inheritance under any circumstances; and in the case where they were more favourably treated, it was almost invariably on their having no brothers.

The custom of *gavel-kind*, which still prevails in Kent, seems to have existed previous to the Conquest, and most probably extended over the larger portion of England and Wales. By this custom, lands within the county of Kent, unless specially excepted by an act of the legislature, descend, where the father dies intestate, leaving sons and daughters, in equal portions to the sons, to the exclusion of the daughters; but in the event of his leaving daughters only, they share the property equally among themselves. This law still exists in the copyholds of the manors of Stepney and Hackney in Middlesex, and in a few other places beyond the bounds of Kent. The custom of *borough English*, by which the youngest son succeeds to the whole of the inheritance on the intestacy of the father, has prevailed in Stamford, and one or two other places, time immemorial. The same custom still exists as to copyholds in different parts of England. But whether, previous to the Conquest, property descended to the sons, or indifferently to both sons and daughters, the introduction of the feudal system led to a change in the succession to property in land, and paved the way for the universal introduction of the custom of primogeniture.

Some writers have taken a very unfavourable view of the influence exercised by this custom in modern times. Adam Smith says, "Nothing can be more contrary to the real interest of a numerous family than a right which, in order to enrich one, beggars all the rest of the children." (*Wealth of Nations*, by M'Culloch, p. 171.) But however apparently reasonable, or however well supported this opinion may be, we are of opinion that it has really no good foundation. How much of the enterprise and industry, of the superior wealth and civilization of modern Europe, may be ascribed to the influence of the custom of primogeniture? It is beyond a doubt that the possession from infancy of a competency is, of all others, the most powerful obstacle to energy and enterprise. Those so situated seldom seek any kind of honourable distinction, and fold their hands in contentment with the humble mediocrity which has fallen to their lot. It is not to be expected that the monied fortunes accumulated for the younger children should equal those of the elder brother. If they be furnished with the means of establishing themselves in a profession, the capacity to rise is put into their hands; the sense of inferiority will stimulate them to exertion, and inspire them with a determination to rise to the same or even to a higher level. It is no rule for the division of property in land to tell us that merchants, bankers, and others of that class divide their property equally among the different members of their families, without any bad effects resulting from it. Such parties may carry on the business in partnership as advantageously as their father. The children of a landed proprietor can with great difficulty do this. The views of the co-heirs, so different and conflicting, are generally found to be all but insurmountable. Add to this, that the custom of primogeniture provides for the cultivation of all that is most elevated in art, in literature, and in science,—of everything, in a word, that communicates splendour and gives an enduring celebrity to nations. While doing so, it imbues all classes with the spirit of industry and enterprise. It does not appear, therefore, that the objections raised against the custom of primogeniture are entitled to any considerable notice. It is not imperative; it is a *custom* only, and not a right, and may be defeated in the event of the misconduct of the eldest son.

Primum Mobile || Prince of Wales Island.

The personal property of one dying intestate shall by this rule be divided—after the widow's proportion is deducted—equally among all the children; but that the real estate shall go, in addition, to the eldest son. There is one respect in which the English law of intestacy stands much in need of revision. The personal property of the intestate is the first fund for their debts, although secured upon their estates; and it is the surplus only, if there be any, that is divisible among the children. This is in all respects a most objectionable arrangement. When an estate is burdened to its full value, the eldest son should have nothing to look to save his share of the personal property. This is in accordance with the law of Scotland. In that country, if the eldest son take the real, he gets no part of the personal estate. He is permitted to renounce the succession to the real property, and have it valued and included in a common fund with the moveable property, of which he can demand an equal share with his brothers and sisters. (*The Succession to Property Vacant by Death*, by J. R. M'Culloch, 1848.)

PRIMUM MOBILE, in the Ptolemaic astronomy, the ninth or highest sphere of the heavens, the centre of which is that of the world, and in comparison with which the earth is but a point. This is supposed to contain within it all other spheres, and to give them motion, turning them quite round, as well as revolving itself, in twenty-four hours.

PRINCE is the Latin *princeps* (*primus-capio*), a word used originally to denote the *princeps senatus* of the Roman state. Originally, he was custos of the city; subsequently the name became a title of dignity, and he was called by the censors. Augustus and his successors adopted the title of princeps, and it was employed henceforward to denote the master of the Roman world. By and bye the term prince came to be applied to individuals having personal pre-eminence, such as the old princes of Wales, who enjoyed the same right and exercised the same power which belong to kings. Of a somewhat different kind were the powers enjoyed by the heads of certain German states comprehended in the Germanic confederation. The term is employed in a somewhat arbitrary manner on the Continent, possessing none of the definiteness which belongs to such words as king, duke, marquess, &c., but rather to denote persons of eminent rank. In England the term is almost entirely restricted to persons of the blood-royal. The eldest son of the sovereign is made Prince of Wales by creation.

PRINCE'S METAL, Prince Rupert's Metal, or Pinchbeck, an alloy of copper and zinc, which has a resemblance to gold.

PRINCE OF WALES ISLAND (called by the natives *Pulo Penang*,—*i.e.*, "Betel-nut Island"), an island belonging to Great Britain, in the Strait of Malacca, off the west coast of the Malay peninsula, lying between N. Lat. 5. 16. and 5. 30., E. Long. 100. 9. and 100. 25. Its form is an irregular oblong; its length 15 miles, breadth at the northern extremity 12, and at the southern 8; area, 160 square miles. The island presents a beautiful and picturesque appearance, the coasts, which are generally bold, being everywhere skirted with groves of cocoa-nut trees, while groups of the graceful betel-nut palm are everywhere scattered over the country, and the hills in the centre are covered with luxuriant forests to within a few hundred feet of their bare summits; and the whole of the country, where not cultivated, is densely wooded. A chain of hills traverses the island from N. to S., rising to the height of 2000 or 2500 feet above the sea. On each side of this chain there are fertile and well-cultivated plains extending to the coast. That on the east, which is known under the name of the Valley, is the more populous of the two, the western plain being swampy and less densely inhabited. In its geological character, Prince of Wales Island belongs to the primitive formation. The mountains are for the most part granitic; mica and quartz are also found in some places. No mineral of value has been obtained from the island, though the mountains are said to be rich in tin ore, which has never been wrought. There are no rivers of any size in the island, but the country is watered and fertilized by many small streams and rivulets. The climate is very healthy, especially in the higher regions, where it is somewhat like that of Madeira. The rainy and dry seasons are not so distinctly marked here as in most tropical countries, for showers fall during almost every period of the year excepting January and February, which are dry months. In the hills the mean temperature of the year is about 70°, and the annual range not more than 10°, while in the valley the heat varies from 76° to 90°. The air is clear and bracing; and this, along with the varied beauty of the scenery, makes Penang a frequent and agreeable resort for invalids.

The island generally possesses a fertile soil, which is for the most part a light black mould mixed with gravel or clay, and in many parts sandy. It is chiefly formed from the decayed leaves of trees, from which originated a fine vegetable mould, the whole island having been for ages covered with immense forests. This has in some degree disappeared as the woods were cleared and the surface exposed to the weather; but the soil in the interior is still very rich. The eastern portion of the island is almost entirely employed in the raising of rice, for which it is very well suited; the south-western side is occupied by plantations of spice and pepper plants. Cloves are grown on the tops of the hills, and tea, cotton, and tobacco on their sides. Coffee, sugar, nutmeg, and many kinds of fruit are also produced here. The forests which are found in this island abound in excellent timber for ship-building and for other uses.

The island contains many buffaloes and cattle, a few goats and sheep, and numerous hogs. The principal wild animals are the Malayan elk, deer, monkeys, wild cats, and snakes. Fish abound in the surrounding seas, and pearly banks have recently been discovered on the east coast. The people of Prince of Wales Island are of very various origin, and there is probably hardly another tract in the world of equal size that is occupied by so many distinct races. The original inhabitants were a few Malays; but after the island was settled by the British, many people from China, India, Siam, Burmah, &c., resorted hither to enjoy the British protection. An active trade is carried on here, as the island is advantageously situated for being an emporium between the countries of China, the East Indian Archipelago, India, and Great Britain. The total value of the exports and imports of Prince of Wales Island in 1854 was L.581,240. This island, along with Province Wellesley, a strip of land on the opposite shore of the Malay peninsula, Malacca, and Singapore, form the Eastern Straits settlements, of which the seat of government is Georgetown, on this island. This town is built on the most easterly point of the island, and has a population of 20,000, chiefly Chinese. When first visited by Europeans, the island was an almost uninhabited waste, overgrown with forests. In 1785 the King of Quedah, to whom it then belonged, gave the island to Captain Light, who had married his daughter; and the East India Company being then desirous of establishing a port on the straits, acquired possession of it on condition of paying annually to the King of Quedah 6000 Spanish dollars, or about L.1275 sterling. Captain Light was appointed superintendent of the settlement, and under him the land was rapidly cleared and improved. Until 1805 Prince of Wales Island formed part of the presidency of Bengal; but in that year it was made a separate presidency; and in 1830 it was united with the other settlements in the straits, and again placed under the government of Bengal. Finally, in 1851, the dependency on Bengal was removed, and the governor declared subordinate only to the government of India. Pop. (1855) 39,589.

PRINCE EDWARD ISLAND, a British colony in North America, on the S. side of the Gulf of St Lawrence, between N. Lat. 45. 58. and 47. 10., W. Long. 62. and 64. 20.; separated from New Brunswick and Nova Scotia on the S. by Northumberland Strait. Its length from E. to W. is about 130 miles, its greatest breadth is 34, and its area 2173 square miles. Its form is very irregular, and its surface is neither mountainous nor monotonously flat, but, like that of New Brunswick, is agreeably diversified with hill and dale. There are no mountains properly so called, but a chain of hills intersects the island from N. to S. about its middle. It abounds with streams and springs of the purest water; and numerous arms of the sea penetrate so far inland that no part of the country is more than 8 miles removed from the flux and reflux of the tide. When first seen, it presents the aspect of a flat country, covered with trees to the margin of the ocean; but, on a nearer approach, the more inviting prospect discloses itself of villages and farms situated in valleys or on green and gentle declivities, with the other smiling features which result from agricultural industry or spontaneous fertility. Unlike Cape Breton, Newfoundland, and other contiguous islands, Prince Edward Island is very rarely visited by fogs; and although the winter is equally severe, the transitions from one extreme to another are less violent. The heat of summer is less extreme than it is in Lower Canada, whilst the cold is not so intense during the winter. Altogether the climate is very salubrious, and there are few countries where health is enjoyed with less interruption.

The soil is fertile, and consists of a thin layer of black or brown mould, composed of decayed vegetables, superimposed upon a light loam. This extends about one foot downwards, and then a stiff clay, resting upon sandstone, predominates. The latter rock is the base of the island, and it appears to extend under the bed of Northumberland Strait, into the contiguous islands, and also into the continent. A solitary block of granite occasionally presents itself; but neither limestone, gypsum, nor coal have been discovered, although their presence was to have been expected from the occurrence of the sandstone formation. Indeed, no minerals of any importance have been found here, and building-stone is so scarce as to be imported from Nova Scotia. A great part of the island was formerly covered with wood, and though large portions have been removed, either for export or to make room for cultivation, there are still considerable remains of the primeval forests. Pine, birch, maple, beech, and other trees are those that compose the forests of the island.

Amongst the quadrupeds native to the island may be mentioned bears, once very numerous and destructive, but now much reduced; lynxes, foxes, hares, and various kinds of fur-bearing animals, whose numbers have been very much diminished. During summer and autumn seals frequent the shores, and they come down in great numbers on the ice of the Polar seas after it has broken up. The rivers abound with excellent fish, such as trout, eel, mackerel, flounders, oysters, lobsters (the last two being very large and very fine), and the coast with cod-fish and herrings. The fisheries of Prince Edward Island are among the best in the Gulf of St Lawrence, but they are not prosecuted to any great extent by the inhabitants. In 1855, 11,249 quintals and 6089 barrels of fish, to the value of L.12,093, were exported from the colony.

Prince Edward Island is essentially an agricultural colony, for which its climate, soil, and the configuration of its surface, admirably adapt it. All kinds of grain and vegetables raised in England arrive here at perfection. Crops of wheat, barley, oats, potatoes, turnips, pease and beans, are raised in abundance and of excellent quality. The produce in 1855 was 357,078 bushels of wheat, 110,629 of barley, 1,380,950 of oats, 1,673,345 of potatoes, 756,557 of turnips, 20,959 of buck-wheat, 6187 lb. of clover-seed, and 3112 tons of hay. Sheep, cattle, and swine thrive well in the island, and the horses, though small, are strong and hardy. The colony had in 1855, 14,513 horses, 55,159 horned cattle, 98,049 sheep, and 32,207 goats. The breed of useful animals generally has been much improved of late years, and agriculture has made decided advances. The manufactures of Prince Edward Island are of little importance, being chiefly destined for domestic use. Linen and flannel, woollen cloth and leather, are the principal articles made. Ship-building, however, is extensively carried on. The number of vessels built in 1854 was 106, tonnage 24,111, value L.168,777; in 1855 the number was 90, tonnage 14,451, value L.86,706. The commerce of the island consists in the export of timber, agricultural produce and live stock; and the importation of manufactured goods, iron, hardware, wines, spirits, tea, tobacco, &c. With the exception of timber, which is all sent to the United Kingdom, the produce of the island finds its chief market in the United States and the British colonies of North America; the imports come in nearly equal quantities from these three sources. The total value of the imports in 1855 was L.268,516, and that of the exports L.144,732. The total number of vessels that entered in the same year was 962, tonnage 53,003; those that cleared were 962, tonnage 60,669. The government of the colony is similar to that of Nova Scotia, of which it once formed a part. There is a lieutenant-governor, with a salary of L.1500; an executive council of nine, appointed by the lieutenant-governor and confirmed by the crown; a legislative council of six, appointed by the crown; and a house of assembly of twenty-four popularly-elected members. The public revenue amounted in 1855 to L.28,054, and the expenditure to L.30,193. About a half of the people are Roman Catholics, about a third Presbyterians, and a ninth Episcopalians. The whole number of churches in the island in 1855 was 127. The number of schools in the same year was 247, attended by 12,187 scholars; and the amount of public money expended for education was L.7946. The population of Prince Edward Island is of mixed origin, about a fourth being emigrants from the United Kingdom, and the rest natives of the country, descended from the French Acadians, or from Scotch settlers, or from loyalists from the United States, who came hither after the Revolution. The colony is divided into three counties, and the capital is Charlotte Town, on an inlet on the south coast.

This island was discovered by Cabot on the 24th of June 1497, being St John's day, and hence derived its original name of St John. The English, however, neglected to avail themselves of this right of possession; and the French, who appear at first to have entertained more correct views of its importance, took possession of it when they made the conquest of Canada, apparently without any remonstrance on the part of Britain. For a long period it continued attached to the crown of France, but it was conquered by Great Britain in 1758. At that time the population in the various settlements appears not to have amounted to 6000. At the peace of 1763 this colony and Cape Breton were confirmed to Britain, and annexed to the government of Nova Scotia; and a plan of settlement was agreed to by which the island was divided into townships, of about 20,000 acres each, granted to individuals who were considered as having claims on the government, and who were to pay a small sum as quit-rent. The plan, however, was unsuccessful, as the grants were in many cases merely used for the purpose of speculation. In 1768 the island was erected into a separate government from that of Nova Scotia, at the request of a majority of the proprietors, and a governor was appointed, who set vigorously about settling the island, and under whom it made gradual progress in prosperity. The colony obtained a complete constitution in 1773, when the first house of assembly met. During the American war it continued true to the interests of the mother country, and was resorted to by ships of war, as well as converted into a military station. As a mark of respect for the Duke of Kent, commander of the British army in America in 1799, and at the same time to remove the confusion of a name common to it with the capital of Newfoundland and New Brunswick, the island was then named Prince Edward Island, a designation it has since retained. Since that period no event has occurred of such moment as to require particular mention here. Pop. (1855) 71,502.

PRINCE'S ISLAND (Portug. *Ilha do Principe*), an island of Africa, belonging to Portugal, in the Bight of Biafra, 140 miles S.S.W. of Fernando Po; length from N. to S., 10 miles; breadth, about 5 miles. It is mountainous and of volcanic origin, the summits of some of the hills rising to the height of 4000 feet. The soil is in general hard and stony, but in some places it is of great fertility. It is watered by many springs and streams. Timber for various uses, and dye-woods, are obtained here in abundance. Much of the island is occupied by plantations of coffee, which is the principal produce, and of which 3487 cwt. were exported in 1842. The atmosphere is extremely moist; and, except for a few months, showers prevail during the whole year. The trade of the island, which was once considerable, has for some time been in a declining condition. St Antao, on the N.E. coast, is the chief town. Pop. of the island, 4584, chiefly slaves.

PRINCES' ISLANDS, or Daimonnisoi, a group of islands, nine in number, belonging to Asiatic Turkey, in the Sea of Marmora, near the entrance of the Bosphorus, from 10 to 12 miles S.E. of Constantinople. Their scenery is exceedingly beautiful; and they contain many villages, gardens, country seats, and convents. The largest of the group is Prinkipo, on which is a town of the same name. One of the most beautiful is Kalki, so called from its ancient copper mines. A steamer sails daily from Constantinople to the Princes' Islands, which attract many visitors by the beauty of their scenery and the amenity of their climate. Pop. of the group, 10,000.

PRINCIPAL. See Agent.

Principal. See Organ.

PRINCIPATO CITRA, a province in the kingdom of Naples, bounded on the N.W. and N. by the provinces of Naples, Terra di Lavoro, and Principato Ultra; E. by that of Basilicata; S. and W. by the Mediterranean. Length from N.W. to S.E., about 80 miles; greatest breadth, 42 miles; area, 2265 square miles. The central chain of the Apennines runs along the eastern boundary, and several branches from it extend into the interior. The greater part of the province is watered by the Sele and its affluents. This river rises in the Apennines near Conza, and flows S. and S.W. until it falls into the sea, not far from the ruins of Pæstum. Its chief tributary is the Negro or Tanagro, which flows from the S.E. through the Val di Diano, and joins the main river from the left. Except this valley, and a level tract of country along the coast, the province is nearly all occupied with mountain ranges. These are for the most part well wooded, especially with chestnut trees. The soil of the valleys is generally rich and fertile; but the plains along the coast for some distance on both sides of the Sele are marshy and unhealthy. The valleys and slopes to the south of the ruins of Pæstum, however, are of a different nature, and have been celebrated both in ancient and modern times for their fertile soil and delightful climate. The principal minerals of the province are copper, marble, and gypsum; and the most important articles of produce are timber, chestnuts, wine, oil, and fruits of various kinds. The principal live stock of the province are swine; and there are productive fisheries along the coast. Paper-making and weaving of woollen and linen fabrics are carried on. There is some trade in timber, dried fruits, hides, and pork. The province is divided into 4 districts, 44 arrondissements, and 165 communes. The capital is Salerno, on the gulf of the same name. Pop. (1856) 583,979.

PRINCIPATO ULTRA, a province of the kingdom of Naples, bounded on the N. by the province of Molise, E. and S.E. by those of Capitanata and Basilicata, S. by that of Principato Citra, and W. by that of Terra di Lavoro; length from E. to W., 47 miles; greatest breadth, 46; area, 1409 square miles. It is almost entirely mountainous, being traversed towards its eastern limits by the central chain of the Apennines, but lying chiefly between that and the lower western ridge of these mountains. Part of this latter ridge is formed by Monte Taburno, the ancient *Taburnus*, which separates this country from the plains on the sea-coast. The chief rivers are the Calore, an affluent of the Volturno; its affluents, the Tamaro and Sabbato; and the Ofanto, which flows eastward into the Adriatic. Principato Ultra enjoys a mild and healthy climate; and the soil is fertile and well cultivated, especially in the valleys. Corn, timber, wine, fruits, &c., are raised; and cattle and sheep are pastured among the mountains. Paper-mills, iron-foundries, and woollen factories are the chief manufactures in the province. Rural produce is exported to a considerable extent. Principato Ultra is divided into 3 districts, 34 arrondissements, and 134 communes. The capital is Avelino. The territory of Benevento, belonging to the Papal States, is entirely surrounded by this province. Pop. (1856) 375,313.

PRINGLE, SIR JOHN, a distinguished physician, was the younger son of Sir John Pringle of Stitchel, Roxburghshire, and was born on the 10th of April 1707. He was educated at home under a private tutor, and subsequently at St Andrews, at Edinburgh, and at Leyden, where he took the degree of Doctor of Physic. He at first settled in Edinburgh as a physician, but was soon after appointed assistant and successor to the professor of moral philosophy in the university. In 1742 he became physician to the Earl of Stair, then commanding the British army in Flanders; and in the same year he was constituted physician to the military hospital there. On the resignation of the Earl of Stair in 1745, Dr Pringle was appointed by the Duke of Cumberland physician-general to the forces in the Low Countries. He returned to Britain during the same year, and was chosen a fellow of the Royal Society on his passing through London. In 1747 and 1748 he attended the army abroad; and in 1749, having settled in London, he was made physician in ordinary to the Duke of Cumberland. He read a series of papers to the Royal Society, which are to be found in the *Transactions*, and which gained for him the gold medal of Sir Godfrey Copley. He married in 1752 a daughter of Dr Oliver, a physician in Bath; and in the same year he published his great work, entitled *Observations on the Disorders of the Army in Camp and Garrison*. In 1761 he was made physician to the household of the young Queen Charlotte, and physician in ordinary to the Queen in 1763. He was raised to the dignity of baronet of Great Britain in 1766, and was in 1768 made physician in ordinary to the King's mother, with a salary of L.100 a year. After having acted for many years as a member of the council of the Royal Society, he was, in November 1772, elected president of that distinguished body. He received his last medical honour in 1774, as physician extraordinary to the King. After passing his seventieth year, he resigned his presidency, and resolved to spend the remainder of his days in his native country. Removing to Edinburgh in 1780, he was doomed to disappointment. He found the place much changed; the keen winds of the northern metropolis were too severe for him; and perhaps these evils were exaggerated by his increasing infirmities. He returned to London in September 1781, and died in the January following, in the seventy-fifth year of his age. There is a monument to him in Westminster Abbey, executed by Nollekens.

PRINGLE, *Thomas*, a man distinguished not more for his poetical talents than for his ill-requited worth, was born at Blaiklaw in Teviotdale in 1789, and attended the university of Edinburgh. Lame, friendless, and barely sustaining himself by acting as a clerk in the Register Office of the Scottish capital, the rustic youth set himself to acquire an honourable position in life. His first efforts were made as much from necessity as from inclination in the province of literature. He became a contributor to Albyn's *Anthology*, and published in the *Poetic Mirror* a poem entitled "The Autumnal Excursion." The notice which these attempts gained induced him to lay down his clerkship for a time, and to devote all his attention to literary pursuits. He started and conducted the *Edinburgh Monthly Magazine*, which was soon changed into *Blackwood's Magazine*. At the same time, he was editing the *Edinburgh Star* and *Constable's Magazine*, and publishing a volume entitled *The Excursion, and other Poems*. His activity, in fact, was in a fair way of securing for him a place in his new profession, until untoward events occurred to drive him to another field of labour. In 1820 Pringle set sail to try his fortune at Cape Colony. He succeeded in gaining the situation of government librarian at Cape Town. He then attempted to eke out his income by establishing an academy, by starting a periodical called the *South African Journal*, and by undertaking the editorship of *The South African Commercial Advertiser*. All these enterprises were succeeding most favourably when the despotic intolerance of the governor compelled him to discontinue them, and to repair to Britain in 1826. The life of Pringle only assumed a more gloomy character after his return to London. It is true that in 1827 he obtained the important and congenial position of secretary to the Anti-Slavery Society; but when that association had attained its object and was broken up in 1834, he was again thrown upon the world. All the efforts and influence he could employ to obtain a public appointment were fruitless. An attack of consumption at the same time rendered it absolutely necessary that he should seek a warmer clime. He was actually preparing to return to the Cape when he died suddenly on the 5th December 1834. Pringle's poetical works consist of stray effusions classed under the two heads of *African Sketches* and *Ephemerides*. They were published in a collected form, accompanied with a memoir of the author, by Leitch Ritchie, London, 1839.

PRINTING.

Printing is the art of taking one or more impressions from the same surface, whereby characters and signs, cast, engraven, drawn, or otherwise represented thereon, are caused to present their reverse images upon paper, vellum, parchment, linen, and other substances, in pigments of various hues, or by means of chemical combinations, of which the components are contained on or within the surface from which the impression is taken, or in the fabric of the thing impressed, or in both.

The most important branch of printing is what is called *letterpress* printing, or the method of taking impressions from letters and other characters *cast* in relief upon separate pieces of metal, and therefore capable of indefinite combination. The impressions are taken either by superficial or surface pressure, as in the common printing-press, or by lineal or cylindrical pressure, as in the printing machine and roller-press. The pigments or inks, of whatever colour, are always upon the surface of the types; and the substances which may be impressed are various. Woodcuts and other engravings *in relief* are also printed in this manner.

Copperplate printing is the reverse of the above, the characters being *engraven* in intaglio, and the pigments or inks contained within the lines of the engravings, and not upon the surface of the plate. The impressions are always taken by lineal or cylindrical pressure; the substances to be impressed, however, are more limited. All engravings in intaglio, on whatever material, are printed by this method.

Lithographic printing is from the surface of certain porous stones, upon which characters are *drawn* with peculiar pencils. The surface of the stone being wetted, the chemical colouring compound adheres to the drawing, and refuses the stone. The impression is taken by a scraper, that rubs violently upon the back of the substances impressed, which are fewer still in number. Drawings upon zinc and other materials are printed by this process. (See Lithography.)

Cotton and calico printing is from surfaces engraven either in relief or in intaglio. The chemical compounds are either on or within the characters, as pigments or chemical colours, or in the fabric to be printed, but mostly in both; the combination of chemical substances producing colour when the fabric and the engraving are brought into contact. The impression is either superficial or lineal, but mostly lineal. (See Dyeing.)

LETTERPRESS PRINTING.

The origin and history of an art which has exercised such an influence on civilization, and contributed in so essential a manner to the cultivation of the human intellect, have naturally become a matter of inquiry amongst the learned, and have almost as naturally been the source of earnest controversy; for there are few effects of human invention or industry that have been originated and brought to perfection at a particular epoch, without any previous train of thought or circumstance, so that the precise day or year could be noted in which the perfect Minerva started forth in full maturity. On the contrary, it is difficult to say at what period of time the germ of the art of printing did not exist. So obvious is the reproduction of similar appearances from an impression of the same surface, that the most early of mankind must have noted it; and even the impression of a foot or a hand must have suggested a simple and intelligible mode of conveying an idea, before the invention of any kind of writing. Accordingly, these and similar signs are found to compose the chief characters of the earliest writing.

Observing this general law of the gradual perfectibility of human arts, we must look back to the most remote ages for the first steps of that of printing. We shall accordingly find certain evidence, that, more than two thousand years before our era, a method of multiplying impressions, rude and imperfect in the extreme, was certainly practised.

The earliest practice which can with propriety be called *printing* was probably that of impressing seals upon a plastic material, the purpose being confined to the single effect of each single impression. The next step of which the diligence of inquirers has taken note, and which is a step thus much further in advance that its object was the multiplication of impressions for the purpose of diffusing information,—the practice, namely, of impressing symbols or characters upon clay and other materials used in forming bricks, cylinders, and the walls of edifices,—was an art confined, so far as our knowledge extends, to the ancient centres of civilization in Egypt and Asia. Some examples of this art found their way many years ago into the great public museums and chief private collections of Europe, where they were objects of curiosity and wonder. In the present day, the researches of Sir Gardner Wilkinson and others into the antiquities of Egypt, and of Sir Henry Rawlinson and Mr Layard into the ruins of the buried cities of Asia, have produced a vast quantity of materials illustrative of the subject. The relative antiquity of the Egyptian and Asiatic remains belong to another inquiry. Among the Egyptian remains are numerous bricks of clay stamped with the *nomen* and *agnomen* of the king inclosed within a cartouche. The mode by which the impressions were made is manifest. The prints are very irregularly placed, without any reference to parallellism with the sides, and are always more or less awry, according to the manual skill and care of the workman: the surface of the bricks around the depression is forced up considerably, which is exactly the effect of pressing the hand or any substance into a plastic material; and the edges, both of the general depressions and of the figures, present the effect of the stamps having been drawn up whilst the clay was yet damp and adherent to it. It is therefore evident that the inscriptions were stamped in after the clay had been turned out of the mould, and were not produced by any part of it. To make the evidence complete, there have been found many stamps of wood, having on the face cartouches and inscriptions precisely resembling in kind those which must have been used for stamping the bricks. On some of these stamps and impressions there are slight traces of colour. Numerous specimens both of the bricks and stamps are in the British Museum, and of the bricks in many collections. There have also been found in Egypt numerous figures of baked clay and porcelain on which hieroglyphic characters have apparently been impressed singly, side by side, by stamps; and on the walls of their ruder buildings hieroglyphic and pictorial figures of considerable size have been produced by the same means and afterwards coloured. Of articles of domestic use are certain instruments called *tesseræ*, having incised characters, the use of which has certainly been to stamp plastic materials; and there have also been found leather belts and ornaments on which figures have been impressed singly by tools.

The ruins of the cities of Asia supply us with numerous examples similar to those of Egypt, but carrying the art farther. The ruins contain countless bricks, on which are impressed inscriptions similar to those of Egypt, but much more elaborate. Mr Layard says, that the characters on the Assyrian bricks were made separately: some letters may have been impressed singly with a stamp, but from the careless and irregular way in which they are formed and grouped together, it is more probable that they were all cut by an instrument and by hand; but that the inscriptions on the Babylonian bricks are generally enclosed in a small square, and are formed with considerable care and nicety; they appear to have been impressed with a stamp, on which the entire inscription, and not isolated letters, was cut in relief. From this circumstance, Mr Layard ascribes greater antiquity to the Assyrian remains.

Mr Layard's researches have further made evident that the ancient inhabitants of these cities practised a more advanced and elegant usage of imprinting in their domestic and ornamental arts. He has discovered great quantities of tiles and tablets covered with *incised* or *incussed* characters, on which was impressed, while the clay was yet wet, a line of characters or symbols,—apparently an authorisation or verification,—produced by the rolling of engraved cylinders; and other tiles, of which he says, "The most common mode of keeping records in Assyria and Babylon was on prepared bricks, tiles, or cylinders of clay, baked after the inscription was *impressed;*"—this impression must not be mistaken for the application of a stamp; it is effected by the use of an instrument in the hand, by which various combinations of the same form were indented into the moist clay, and therefore partakes more of the character of *impressed writing:* in many of the specimens thus impressed, the writing (or text) does not cover the entire tile or tablet, and the blank is filled up by repeated impressions of the same seal; and in some cases the entire text has been surrounded by an impression from a cylinder rolled round, forming an endless scroll, by which any addition to the text is rendered impossible. Great numbers of cylinders have been found. They are elaborately engraven on various stones; some are perfect cylinders, some barrel-shaped, others slightly curved inwards. Others again are of baked clay, on which the characters have been *incussed* while the clay was yet moist. Many of them are perforated longitudinally, and revolve on a metal axis. In describing an engraved cylinder of great beauty found in the mounds opposite Mosul, Mr Layard says, that on each side there were sixty lines written in such minute characters, that the aid of a magnifying glass was required to ascertain their forms. The habitual use of these elaborate articles is unknown,—by some they are supposed to be charms,—by others, records of family or personal transactions. The smaller examples, we have seen, were used to impress plastic materials as signets; but it is clear, from the shapes of the greater number, and from the circumstance that the characters they bear are invariably engraven or impressed in the order in which they are to be read, and not reversed, that they were not intended to multiply impressions on soft surfaces by way of diffusing information. In the library of Trinity College, Cambridge, has long been preserved a very celebrated Babylonian cylinder of clay, baked to vitrifaction. It is barrel-shaped, about 7 inches in length, and 3 in diameter at the ends. There are two inscriptions, separated by a blank band round the centre. The inscription is in vertical lines (counting on a drawing), thirty-two in number, consequently each less than a quarter of an inch in width. In one of the columns there are thirty characters; consequently, in both inscriptions there will be about 1800 characters. The cylinder presents many appearances of having been formed in a mould. It was presented to the college by the late Sir John Malcolm.

That a similar art was known to the inhabitants of the old world generally, may safely be assumed. It is therefore not a little remarkable that peoples so original and ingenious as the Greeks, and so imitative as the Romans, should have left almost no vestige of their having practised any such means as this to multiply their beautiful creations of fancy, or to embellish the tasteful appliances of domestic life; especially when we consider the easy application of the art to pottery, and the beauty, taste, and ingenuity which they exhibited in that manufacture. For, excepting a few paltry designs *en creux* on some of the coarser specimens, and a few marks upon the Roman military vessels, evidently stamped, there is no appearance of either people having had any idea of this kind. There are, however, in the British Museum numerous instruments presenting a singular instance how very nearly we may approach to an important discovery, and yet pass on unheeding. These are stamps of various sizes, having on their faces inscriptions in raised characters reversed. The material is brass or bronze. The letters of the inscriptions are considerably raised, and the face of them is rough and rounded, as though they were rudely cast in a mould. To the back of most a handle has been fastened; some have a loop to allow the fingers to pass through; some a boss to rest in the palm of the hand; some a ring. One use of these stamps has probably been to press the inscription into a soft material; but the more common application, especially of the smaller specimens, has evidently been to *print* the inscription on surfaces by the aid of colour. It has been suggested that their purpose was to imprint the coverings of bales of goods with the marks of their owners. Among relics of this kind is the signet of C. Cæcilius Hermias. The face of this is two inches by four-fifths of an inch, and the inscription (reversed)

CICAECILI
HERMIAE. SN.

with a border, is in relief, the surrounding parts being cut away to a considerable depth. It should be especially noticed, that the surface of the back-ground is very rough; and there is a ring at the back by which it could be handled or suspended.[1] These circumstances render the use of it very clear. It would be very much easier to incise the required inscription, and to let the field stand (indeed the art of engraving *en creux* was well known and used), than to cut away the field and leave the letters in relief; and it would produce a much more beautiful effect if it were used to impress any soft substance; whereas, cut as it is, the impression sunk into wax or clay would not only be ugly, but illegible, and the rough surface of the back-ground would present the most ungainly appearance upon the prominent parts of the wax, being the parts most presented to the eye. Its use therefore is evident. The relieved inscription, and no other part, being covered with ink or pigment, was impressed upon an even surface (papyrus, linen, parchment), and consequently left a perfect but reversed imprint of itself. This is the precise effect of printing with types. From the Greek *agnomen*, Cæcilius probably lived under the emperors, when literature had become one of the pursuits of the great, and when the difficulties and expense of procuring books by the slow process of copying were bitterly felt. It is singular, therefore, that the Romans should have overlooked so obvious an improvement upon their own signets as the engraving whole sentences and compositions upon blocks, and thence transferring them to paper—even if they had gone no farther than this.[1]

---

[1] The Antiquarian Society of Newcastle possesses a similar stamp with a Greek inscription.

From this time a vast period elapses before any circumstance can safely be instanced as showing that the practice of transferring characters was known to any, even comparatively civilized people. From the rough and imperfect attempts above indicated an early and obvious advance was engraving pictures upon wooden blocks. The first practice of this is involved in obscurity; but most writers on the fine arts agree that the art was invented towards the end of the thirteenth century, by a brother and sister of the illustrious family of Cunio, lords of Imola, in Italy. By some the whole narrative is considered as apocryphal, but it is nevertheless generally admitted. The engravings were discovered by a Frenchman of the name of Papillon, in the possession of a Swiss gentleman, M. de Grœder, who deciphered for him the manuscript annotations found upon the leaves of the book in which they were bound. These purported that the book had been given to Jan. Jacq. Turine, a native of Berne, by the Count of Cunio, with whose family he, Turine, appears to have been intimately acquainted. Then follows a romantic history of the twins, and the cause of their invention. The book is entitled—"The Heroic Actions, represented in figures, of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, presented, and humbly offered to the most Holy Father Pope Honorious IV., the glory and support of the Church, and to our illustrious and generous father and mother, by us Alessandro Alberico Cunio, cavaliere, and Isabella Cunio, twin brother and sister; first reduced, imagined, and attempted to be executed in relief, with a small knife, on blocks of wood, made even and polished by this learned and dear sister; continued and finished by us together, at Ravenna, from the eight pictures of our invention, painted six times larger than here represented; engraved, explained by verses, and thus marked upon the paper, to perpetuate the number of them, and to enable us to present them to our relations and friends, in testimony of gratitude, friendship, and affection. All this was done and finished by us when only sixteen years of age." (*Ottley.*) This title is here given at full length, because, if genuine, it presents us at once with the origin, execution, and design of these first attempts at block-printing. The book consists of nine engravings, including the title; the figures are tolerably well designed, and the draperies graceful, with here and there attempts at cross-hatching; under the principal personages are their names; above, are inscriptions indicating the subject, and below, four lines of poetical Latin explanatory of it; and in some part of each print is an inscription indicating the share the twins respectively had in the execution. The colour of the pigment is gray.

The first subject is Alexander on Bucephalus. Upon a stone, *Isabel. Cunio pinx. et scalp.*

The second subject, the Passage of the Granicus. *Alex. Alb. Cunio Equ. pinx. Isabel. Cunio scalp.*

The third subject, Alexander cutting the Gordian Knot. *Alex. Albe. Cunio Equ. pinx. et scalp.*

The fourth subject, Alexander in the tent of Darius. *Isabel. Cunio pinx. et scalp.*

The fifth, Alexander giving Campaspe to Apelles. *Alex. Alb. Cunio Eques. pinx. et scalp.*

The sixth, the Battle of Arbela. *Alex. Alb. Equ. et Isabel. Cunio pictor. et scalp.*

The seventh, Porus brought to Alexander. *Isabel. Cunio pinx. et scalp.*

The eighth, the Triumph of Alexander upon his Entry into Babylon. *Alex. Alb. Equ. et Isabel. Cunio pictor. et scalp.*[2]

From the dedication of this book to Pope Honorius IV., it is deduced that these engravings must have been executed between 1284 and 1285, inasmuch as this pope only enjoyed the pontificate two years; and it is suggested that a copy of it might be found in the library of the Vatican. The narrative appears to be confirmed by many incidental circumstances, which could not be the invention either of Papillon or his informer. The name of Alberico seems to have been a favourite with the family of Cunio, and a Count of that name actually figures in history in the very year of the presumed invention; a relative of the twins, of course, not the male artist himself.

The interval between the time of the twin Cunio and the next mention of any similar usage is very perplexing; but upon examination it will appear that that long period was not altogether a blank in the art. The next earliest evidence is a document of the government of Venice, discovered amongst the archives of the Company of Printers in that city. It bears the date of 1441, and as it throws some degree of light upon the controversy relative to the invention of printing, it is here given from Ottley's *History of Engraving.*

"MCCCXLI. October the 11th. Whereas the art and mystery of making cards and printed figures, which is used at Venice, has fallen into total decay; and this in consequence of the great quantity of playing-cards, and coloured figures printed, which are made out of Venice; to which evil it is necessary to apply some remedy; in order that the said artists, who are a great many in family, may find encouragement rather than foreigners. Let it be ordered and established, according to that which the said masters have supplicated, that from this time in future, no work of the said art that is printed or painted on cloth or on paper, that is to say, altar-pieces (or images), and playing-cards, and whatever other work of the said art is done with a brush or printed, shall be allowed to be brought or imported into this city, under pain of forfeiting the works so imported, and xxx livres and xii soldi, of which fine one-third shall go to the state, one-third to the Signori Giustizieri Vecchi, to whom the affair is committed, and one-third to the accuser. With this condition, however, that the artists who make the said works in this city may not expose the said works to sale in any other place but their own shops, under the pain aforesaid, except on the day of Wednesday at St Paolo, and on Saturday at St Marco, under the pain aforesaid." (*Ottley.*)

---

[1] The Chinese printing is not unlike this, and must by no means be supposed to have much similarity to the modern art. They assert that it was used by them several centuries before it was known in Europe; in fact, fifty years before the Christian era. They certainly may have used their method centuries before our art, for it differs in nothing but extent from that of the old Roman. The following is a description of their method at the present day, and it is probably the same in every respect as that in practice two thousand years ago in an empire where nothing is changed. As their written language consists of from eighty to one hundred thousand characters, it would be utterly impracticable to use moveable types, and the use of block-printing would be the most easy and rapid. The sentences, therefore, desired to be multiplied, being drawn upon their thin paper, this is made to adhere with the face downward to a block of soft wood, so that the characters appear though *reversed.* The plain wood is then cut away with most wonderful rapidity, and the drawing left in relief. Both sides of the block are similarly operated upon. The engraved wood is then properly arranged upon a frame, and the artist, with a large brush, covers the whole surface, the field as well as the relief, with a very thin ink; he then lays very lightly over it a sheet of paper, and passes a large soft brush over it, so slightly, yet so surely, that the paper is pressed upon the raised figures, and upon no other part. The rapidity with which this is performed is extraordinary; for Du Halde asserts that one man can print 10,000 sheets in one day, a number which would appear incredible, did not very good testimony exist at the present time that one man can print 700 sheets per hour. The method of putting the thin sheets together when printed is as different from ours as their printing and mode of reading. The sheets are printed on one side only; but instead of the blanks being pasted together to form one leaf, the sheet is so folded that no single edge of paper is presented to the reader, but only the double folded edge, the loose edges being all at the back of the book. The late emperor had punches or matrices cut, from which copper types were cast; but the number of characters required—about 60,000—is so great, that composition is almost impracticable.

[2] It is not unlikely that the twins may have been directed in the choice of their subject by the identity of the name of the great conqueror with that of the brother; at least such coincidences are not without parallel in the history of literature.

From this it seems manifest that the art of printing from wood-blocks was not lost, but, on the contrary, had been so long practised as to become an extensive and profitable business in Venice, and had spread over the Continent to such a degree as to destroy the trade of the Venetian artists. The establishment of an important manufacture, and its decay, necessarily infer a long period. From the constant conjunction of the two arts of painting and printing in this document, we may infer (what the existence of prints and cards of later date prove) the method in which these figures and cards were manufactured, namely, that the outline was first printed, and that the colours and shading were filled in by the painter and illuminator. The history of playing-cards now becomes of some importance to the narrative. When cards first came into use is uncertain; but mention is made of them in the year 1254, when they were interdicted by St Louis on his return from the Crusade: they were also forbidden by the Council of Cologne in 1281. In 1299 they are expressly mentioned under the name *carte;* and in *Das Gülden Spiegel,* printed by Gunther Zainer in the year 1472, it is said that cards first came into Germany in 1300. An old French poet, who wrote "En l'an mil iij cent xxviij," has the line, "Jouent aux dex, aux cartes, aux tables." (See CARDS.) There is no evidence earlier than the Venetian decree to connect the art of printing from wood-blocks with the art of making cards; but as it is evident from that document that such connection did exist, it is a fair presumption that it originated not very long after the introduction of the game; and as the sum paid by Charles VI. for "trois jeux de cartes" was so small as fifty-six Parisian sols, it has been conjectured that they must have been illuminated prints. The Venetian decree against the importation of painted and printed figures from abroad now brings us to the country from which the chief export was made. It appears, therefore, that in the Low Countries the manufacture was carried on to a great extent; and we shall also find that in Holland and Germany, and probably over most of Europe, religion had called this art to her aid; that whilst the noble and wealthy recreated the mind and delighted the eye with the exquisite productions of the scribe and illuminator, the more humble were equally gratified with rude and simple illustrations of interesting portions of Scripture, or pictures of favourite saints. It is probable that the poorer classes hung up these drawings in their dwellings, where they excited as true and heartfelt devotion as the masterpieces of the painters' art in the oratories of the great. There is no evidence how early the art was practised, nor whether the outlining the figures of saints and sacred subjects preceded the printing of cards, or was suggested by the latter; but it is certain that at the end of the fourteenth and the commencement of the fifteenth century the practice was very common. The impressions were taken by means of a burnisher, the gloss caused by the friction being distinctly visible on the backs both of cards and prints preserved to this time. As facility in practice increased, a distich or quotation illustrative of the print became a natural improvement; and to this was frequently added a coat of arms, the name of the saint, or the title of the subject, all in the field, or over the head of the figure; and, lastly, sometimes a date. The earliest print of which the date is given within the print itself,[1] is a wood-cut of St Christopher carrying the infant Jesus across the sea. It is of folio size, and coloured in the manner of our playing-cards. At the bottom is the inscription,—

Cristofori faciem die quacunque tueris
Illa nempe die morte mala non morieris.

Milleſimo cccc°
xx° terno.

It was found in the monastery of Buxheim, near Meiningen, and is now in the possession of Earl Spencer.

The next advance was obvious. Instead of a single block, a series of blocks were employed, with additional literary illustrations; and thus were the first printed books formed. The earliest and most memorable of these are the *Historia Sancti Johannis Evangelistæ*, the *Ars Memorandi*, the *Ars Moriendi*, the *Biblia Pauperum*, the *Historia Virginis Mariæ*, and the *Speculum Humanæ Salvationis.* (See BIBLIOGRAPHY.) The most important of these works is the *Historiæ Veteris et Novi Testamenti seu Biblia Pauperum*—truly the Poor Man's Bible. It consists of forty leaves printed upon one side of the paper only, by friction, from as many blocks; the colour is brown; the prints are placed opposite to each other, and the blank backs are pasted together into one strong leaf. The cuts are about 10 inches in height, and 7½ in width. Each print contains three sacred subjects in compartments, and four half-length figures of prophets in smaller divisions, two above and two beneath the principal subjects. Latin inscriptions are on either side of the upper figures, rhythmical verses on either side of the lower, and additional inscriptions are on labels at the bottom of the whole. The central subjects are from the New Testament, the others from the Old, and in some manner allusive to the former. There are many copies of this work, evidently from different blocks, and of different dates. Indeed it appears to have been a most popular book, and was printed repeatedly long after the introduction of legitimate printing; there are several editions in which the inscriptions are actually printed with moveable types. The exact date of these curious works is not ascertained; but Dr Horne possessed a copy contained in one volume with the *Ars Moriendi* and the *Apocalypse*, all works of the same style, the binding of which bore the date of 142( ). The original composition and design of this work is attributed, and not without some show of reason, to Ansgarius, who was bishop of Hamburg and Bremen in the ninth century. (See Plate II.)

A similar book is the *Canticles*, a small folio volume of thirty-two subjects, two being printed on each leaf, and on only one side of the paper, and the leaves also pasted back to back. It differs from the *Biblia Paperum* in that the inscriptions are engraven on scrolls fantastically dispersed amongst the figures. This is generally allowed to be of somewhat later date than the preceding, and to hold an intermediate space between it and the *Speculum Humanæ Salvationis*, to which a larger space must be devoted, on account of its importance in the controversy relative to the invention of printing.

---

[1] There is said to be a print at Lyons with the date 1384, but its existence is doubtful. There has lately been discovered a print with the date of 1418, but its authenticity is yet under discussion. It was found by an inhabitant of Malines, who, in breaking up an old coffer which had been used to contain the archives of the former *Grand Conseil* of Malines, observed an ancient-looking print pasted inside the lid. The subject is the Virgin and Child, with Saints Catherine, Dorothy, Barbara, and Margaret, within a palisaded enclosure. On the top-bar of the gate is the date m : cccc °xviii. distinct and unmistakeable. The design and execution are very superior to those of the St Christopher and the block-books. The *Athenæum* of 1844 contains a full description of the print, and the volume of 1845 a *fac-simile.* The earliest dated print taken from an engraved metal plate is by Maso Finiguerra, 1460.

This is not, strictly speaking, a block-book; for whilst the form of the design and the portion of Scripture represented are engraven on wood, the inscription is in some cases engraven on wood also, but in others is printed in *moveable type*. The Latin edition, *perhaps* the first, consists of sixty-three leaves, divided into five unequal gatherings. The subjects are chiefly from the Old and New Testament; but sometimes such stories have been selected from ancient history as might seem in some way appropriate to the events recorded in sacred writ. Each subject has a short Latin inscription underneath it, and the text occupies the remainder of the page. Its size its folio; the impressions are taken with a burnisher, on one side of the paper; the colour of the ink is brown, and the backs are pasted together, as in the books previously described. The work is certainly of nearly the same date, though probably a little later, than the *Biblia Pauperum;* and it may even have been in part executed by the same artist, for in the earlier portions there is so much general resemblance, both in design and execution, as to make it probable that the same graver was employed in both. The latter part, however, is the work of another artist; the lines are not so bold, and there is an attempt at fineness of execution, of shading, and of distance, which the earlier master did not attempt; the design, though in better drawing, is not so spirited; the drapery is more correct, though not so graceful; and in fact the engraver was a better workman, but not so great an artist. It must be understood, that there are numerous editions of this work, many differing in essential particulars, but some so nearly similar as to require a microscopic eye to detect the variations. Of four of these, two are in Latin, two in Dutch; and between these four lies the contest for antiquity. Mr Ottley (whose beautiful *History of Engraving* contains a well-drawn-up account of his inquiry, illustrated by most convincing examples) has, from a minute and laborious examination, decided that the two Latin and two Dutch are printed from the self-same blocks, and by comparing them, and finding evidences of fractures in the one which do not exist in the other, he has very satisfactorily awarded the palm of antiquity. First, although the Latin inscriptions in the earlier part of the *first* Latin edition (so called by commentators) are engraven on blocks of wood, these blocks are not of the same piece as the figures, the work having been divided between two artists, the one more skilled in engraving figures, and the other in engraving letters. *Secondly*, parts of the engraving broken in the *first* Dutch are perfect in the *first* Latin; parts imperfect in the *first* Latin are unbroken in the *second* Dutch, whilst the *second* Latin is the most perfect of all; from which the conclusion is drawn that the *second* Latin is the most ancient, then the *second* Dutch, next the *first* Latin, and lastly the *first* Dutch. This order of succession is of considerable importance, because the *first* Latin is printed with moveable—some commentators say fusile—types. The printing of this work is claimed for Laurence Koster.

But by whomsoever these curious works were printed, they bring us to the very threshold of the invention of printing, in the proper sense of the word. Bibliographers agree that the pictorial parts of the *Biblia Pauperum*, the *Canticles*, and the *Speculum* were engraven by the same engraver, but from the designs of different artists; and that while of the *first* Latin edition (placed *third* by Ottley) the plates numbering 1, 2, 4, 5, 6, 7, 8, 9, 10, 11, 13, 14, 16, 17, 21, 22, 26, 27, 46, are printed entirely from wooden blocks, the five leaves of which the preface consists, and the text of the remaining leaves—(there are 63 in all)—are printed from *moveable type*. Therefore, between the printing of the first edition of these three works, and the third of the *Speculum*, the art of printing with moveable type had become known to the printer. [Sotheby's *Principia Typographica* contains a great number of *fac-similia* of block-books, water-marks, &c., and an ingenious disquisition.]

We have now come fairly to the practice of printing in the real sense of the word; and we have also arrived at the long-pending, long-controverted question, of who invented it, and where? The honour is disputed by as many cities as contended for the birth of Homer. Only three of these can show the slightest argument for their pretensions; Harlem, Strasbourg, and Mentz. Harlem claims it for her citizen Laurence Koster, or Laurent Janszoon Koster (or Custos). The claim rests principally upon the narrative in the *Batavia* of Hadrianus Junius, a native of West Friesland, who dwelt at Harlem. The work was written in 1575, but not published until 1588. The following is a close translation of the narrative :—

"There lived, a hundred and twenty-eight years ago, at Harlem, in houses sufficiently splendid (as a workshop, which remains to this day entire, can serve as proof), overlooking the forum from the neighbourhood of the royal palace, Laurentius Joannes, by surname *Æditus*, or Custos[1] (which at that time lucrative and honourable office an illustrious family of that name [or, *a family illustrious by that name*] held by hereditary right), the person who now seeks back by just avouchments and oaths the lapsing glory (*recidivam gloriam*) of the invention of printing, nefariously possessed and seized upon by others [the man], with the greatest right to be presented with the greater laurel of all honours (*summo jure omnium triumphorum laurea majore donandus*). He by chance, walking in a suburban grove (as was the fashion of citizens in easy means to do after dinner in those days), began first to fashion beech-bark into letters, which being impressed upon paper, reversed in the manner of a seal, produced one verse, then another, as his fancy pleased, to be for copies to the children of his son-in-law; which when he had happily accomplished, he began (for he was of great and acute genius) to agitate higher things in his mind, and first of all devised with his son-in-law, Thomas Peter, who left four children, all of whom obtained the consular dignity (a thing which I mention that all may understand the art arose in an honourable and talented, not a servile family), a more glutinous and tenacious species of writing ink, which he had commonly used to draw letters; thence (*experiretur*) he expressed entire figured pictures with characters added; in which sort I have myself seen *Adversaria* printed by him, the traces of the works (*operarum*) being only on opposite pages, not printed on both sides (*haud opistographis*). That book was in the vernacular tongue by an anonymous author, bearing for title *Speculum Nostræ Salutis;* in which it is to be observed among the first beginnings of the art (for never any is found and perfected at once), that the reverse pages being smeared with glue, were stuck together, lest they, being blank, should present a deformity. Afterwards he changed beech-blocks for lead;

---

[1] In the original, Koster is simply said to have been surnamed *Æditus*, seu *Custos*, but no mention is made of the Cathedral. The statement, therefore, that he was curtos of the cathedral is a gratuitous insertion of after narrators. The word Custos has been Dutchified into Coster or Koster; but there is no apparent reason why we may not suppose that *Custos* was a barbarous Latin word for keeper, or constable, or any other translation the word will bear.

afterwards he made them of tin, because it was a material more solid and less flexible, and more durable: from the relics which remained of which types very ancient wine-flasks being made, they are to this day to be seen in those houses of Laurentius which I have mentioned looking upon the forum, inhabited afterwards by his grandson Gerard Thomas, whom I name for honour's sake, a noble citizen, who departed this life a few years ago. The studies of men favouring, as it happened, the new art, since a new merchandise, never before seen, brought buyers from every side with most eager quest, at once the love of the art increased, the establishment (*ministerium*) increased, workmen in the art being added to the family, the first touch of evil; among whom was a certain Joannes, either (as the suspicion is) that Faustus of ominous name, faithless and unlucky (*infaustus*) to his master, or some other of the same name, I do not greatly care which, because I am unwilling to disquiet the shades of the silenced, touched with the plague of conscience while they lived. He being sworn by oath to the processes of printing, after he had (as he thought) learned thoroughly the art of putting the characters together, the knowledge of fusile types, and whatever else may relate to the matter, taking an opportunity, than which he could not have found one more fit, on the very eve which is sacred to the birth of Christ, on which all in common are accustomed to labour at the sacred ceremonies, stole the whole materials,[1] tied up a package of the instruments of his master used in that art (*instrumentorum herilium ei artificio comparatorum supellecticem convasat*); thence with a servant hurried from the house, went in the beginning to Amsterdam, thence to Cologne, until he arrived at Mayence, as to the altar of an asylum, where he might live safe beyond the reach of arrows (as the saying is), and having opened an office, enjoyed the rich fruit of his robberies. Indeed, from it, in the space of the (or a turning) year, in the year 1442 from the birth of Christ, with the same types which Laurentius had used at Harlem, it is certain that he produced to light the *Doctrinale* of Alexander Gallus, which grammar was then in most famous use, with the *Tractates* of Peter Hispanus, his first productions. These are, for the most part, things which I have formerly heard from aged men worthy of belief, who have received them as things delivered from hand to hand, as a torch in a race, and have found others relating and attesting the same things. I remember that Nicholaus Galius, the instructor of my youth, a man with iron memory, and venerable for his long years, related to me, that when a boy he had heard, not once only, a certain Cornelius, a bookbinder, and rendered serious by age, nor less than eighty years old (who had lived as an under workman in that office), relating with much mental anger, and with fervour, the course of the proceeding, the manner of the invention (as he had received it from his master), the improvement and increase of the art, and other things of the kind; and that the tears would burst from him against his will at the shame of the affair, as often as he talked of the robbery. Which things do not differ from the words of Quirinus Talesius Con., who confessed to me that he had formerly the same from the mouth of the same bookbinder."

Beyond this narrative of Hadrian Junius there is little, or rather no testimony to the truth of Koster's claim, all subsequent argument being either drawn from or referred to this statement. Many very learned bibliographers have given full credence to Hadrian; whilst others not less acute absolutely deny Koster any pretence whatever—Santander calling in question his very existence; and there is a third party who, being unable to decide between the opposing arguments, and willing to take refuge in a middle course, allow to Koster the credit of having invented printing from blocks, but assign to his rivals that of printing from moveable types.

The whole argument may, however, be reduced into a reasonable compass. The probability of Hadrian's narrative will naturally be the subject of inquiry. *First*, the roundabout way in which this hearsay evidence reached Hadrian, is in itself an unsatisfactory circumstance. Little belief can be accorded to an uncertain bookbinder, even had any circumstances been adduced besides the name Cornelius, by which this bookbinder could be identified. *Secondly*, Talesius was many years secretary to Erasmus, who, although a Dutchman and resident in Holland, repeatedly and unhesitatingly ascribes the invention to John Gutenberg of Strasbourg at Mentz.[2] It is not at all probable that, had Erasmus ever heard of this story, or given the slightest credence to it if he had, he would have omitted some mention of a circumstance so gratifying to his national vanity; or that he should have remained in ignorance of a story well known to his secretary, and commonly bruited about, and therefore known to some of the learned men amongst whom Erasmus lived. *Thirdly*, the story of the engraving on beech-bark accidentally, when it is quite certain that the art of taking impressions from wood-blocks of the figures of cards and of saints and sacred subjects, with religious and legendary inscriptions, had been known and extensively practised, not only in Italy and Germany, but in Holland itself, for more than a century, is absurd. *Fourthly*, every author who has written upon the matter has given up all claim on Koster's behalf for the invention of cast type, the evidence in favour of others being too strong to be got over. *Fifthly*, the tale of the conversion of the relics of these types into drinking-cups, which were yet to be seen (1575), is discredited by the circumstance that no one has since seen or heard of them, although a controversy for the honour of a discovery in which they would have been evidence, was even then and has ever since raged furiously. *Sixthly*, the story of John Fust having stolen all his printing materials on the eve of Christmas, and decamped, first to Amsterdam, then to Cologne, and lastly to Mentz, and his publishing there within the same year, is self-contradictory; for type is not a very portable commodity; nor would he easily have escaped pursuit at Amsterdam, a town under the same government. Again, John Fust was originally no printer, but a wealthy goldsmith of Mentz, and certainly never worked as any printer's journeyman. Indeed this is such a palpable mis-statement, that commentators upon Hadrian have boldly supposed that the thief was John Gutenberg,—not he of Mentz, but a brother, also named John. Unfortunately Gutenberg's brother was not named John, but Friele; there was a cousin John; but the only evidence by which we become aware of the existence of these persons excludes the supposition that either practised the art; nor is it at all likely that members of a noble family, and wealthy men, should have worked in the service of any man. If it should be asserted that it was *the* John Gutenberg, his time is so well accounted for that it is impossible, since he was then resident at Strasbourg, and never was at Amsterdam or Cologne. Thus, then, the narrative of Hadrian Junius appears upon examination to be utterly incredible, being at once at variance with itself and with all probability.

Arguments for and against the claim of Harlem may be urged not derived from this narrative. Although these circumstances are not to be believed, the main facts *may* nevertheless be correct. Koster *may* have printed the *Speculum* and other block-books attributed to him. Ottley says that they were certainly printed in Holland, for that the types are not those used in Germany, but closely resembled such as were afterwards cut or cast in Holland; and that they are of greater antiquity than any books printed by those who afterwards used the art in the Low Countries. He also attempts to show, by the water-marks in the paper, that the works in question were produced in these parts. Water-marks, however, and some bearing a general resemblance to these, were common in the papers used by printers of Cologne, Louvain, and elsewhere; and the argument is worth little or nothing, for no evidence can be given even of the dates of these works, and much less of the printer. The *Speculum* was printed again and again after the invention of letterpress printing; nor is there the slightest evidence, supposing these assertions to be correct, to connect them with the name of Koster. It is a conclusive argument *against* him, that those other works ascribed to him and his descendants are executed with the self-same types used at Utrecht in 1473 by Ketelaer and De Leempt. Van Mander, who lived at Harlem in 1580, in his *History of the Lives of Dutch Painters and Engravers*, treats the claim of Harlem with contempt; for, speaking of printing, he describes it as an art "of which Harlem, with much presumption, arrogates to herself the honour of the invention;" nor does he make the slightest mention of his famous fellow-citizen. There is not the least evidence that his *three* grandsons (not *four*, as Hadrian says) ever carried on his business; for where are their works? and in their time printers had become so proud of their art as not only to put their names to every work, but even to add a long history of their undertaking and progress. Where are the books ascribed to them? what mention is made of them by their contemporaries? In a subsequent part of this article it will be seen that Caxton, the first English printer, is asserted to have been sent to Harlem to learn the art, and if possible to carry off one of the workmen. These things being also matter of controversy, cannot fairly be used in argument; nevertheless it is of some value that Caxton, who, supposing it to be true, would be an excellent witness in favour of Harlem, upon all occasions refers the invention to Gutenberg, and makes no mention whatever of Harlem or Koster.

---

[1] Or whatever else *choragium* may mean; literally it signifies the *properties* of a theatre.

[2] Anno Christi 1440. Magnum quoddam ac pene divinum beneficium collatum est universo terrarum orbi, a Johanne Gutenberg Argentinensi, novo scribendi genere reperto. Is cum primus artem impressoriam, quem Latini vocant *excusoriam*, in urbe Argentinensi invenit; inde Moguntiam veniens eandem feliciter complevit. (*Epit. Rerum Script.* 1502, cap. 95.)

Santander labours to disprove the very existence of any such person. But there is no necessity to go so far as Santander: we may allow Koster's identity; we may even allow that he practised the art of taking impressions from wood-blocks; but this is very different from acknowledging his claim to the invention of the art of printing. The most strenuous champion of Koster is Meerman, an eminent French bibliographer of the last century, who, in his *Origines Typographicæ*, published at the Hague in 1765, strongly maintains this narrative of Hadrian; which is not a little singular, seeing that the Newcastle Typographical Society published a letter from him to Wagenaar, of eight years' prior date, in which he expresses a precisely contrary opinion. He calls Seitz's (Hadrian's) story a mere supposition, and the chronology a romantic invention; gives to the *Speculum* the date of 1470 as the earliest possible; attributes the honour to Gutenberg, and incidentally mentions his intention of publishing a pamphlet on the subject. Notwithstanding this, in his work, without any new fact whatever, he accredits Hadrian's story, finds consistency in the dates, believes the *Speculum*, and denies John Gutenberg,—completely reversing his previous conclusion, though his premises remain the same.

The statement of Ulric Zell, given in the *Cologne Chronicle*, though always referred to by bibliographers, has not received the attention it seems to deserve. Ulric Zell is supposed to have been one of the workmen employed in the office of Fust and Schœffer at Mentz, when that city was taken by the Count of Nassau in 1462. On this event Zell betook himself to Cologne, where he established a press, from which in 1467 he issued his first work. He continued to carry on the art in this city for many years. The *Cologne Chronicle* was printed by Koelhoff in 1499. Under the head of "Invention of Printing," it contains an account of its discovery communicated by Ulric Zell, which, considering the place where it was published, the nearness of the time, and the intimate connection of the narrator with the first movements of the art, carries great weight.

"*Item*, this most worthy art aforesaid [was] first of all invented [*vonden*] in Germany, at Mayence, on the Rhine; and that is a great honour to the German nation, that such ingenious people are to be found there; and that happened in the year of our Lord 1440.

"*Item*, although the art was invented at Mayence as aforesaid, in the manner it is now commonly used, yet the first idea [*verbyldung fonden*] originated in Holland from the Donatuses, which were printed there even before that time; and from out of them has been taken the beginning of the aforesaid art, and has been invented much more masterly and cunningly than it was according to that same method, and is become more and more ingenious."

Now we know that the *Donatuses* were block-books of a rude form, in no way resembling the art used by Zell and his contemporaries; and such as they are, there is no evidence that Koster printed any one of them.

All evidence, then, and the general consent of the learned, in failure of Koster, unhesitatingly ascribe this invention to

JOHN GUTENBERG, surnamed Genzfleisch, Gensfleisch, or Gensefleisch, von Solgenloch or Sorgenloch. He was a native of Mentz, and of a noble family, possessed of considerable property in various places in the neighbourhood. Fortunately the life of Gutenberg does not rest merely upon hearsay evidence, or the doubtful guesses of bibliographers from dateless woodcuts; legal documents supply most important information. It appears that, for some reasons unknown, he resided for many years at Strasbourg, and had even acquired rights of citizenship. The first document presents him in no amiable light. It is a lawsuit instituted to compel him to perform his marriage-contract with Anne von Isernen Thür; and it would appear that he was compelled to make good his promise, the name of Anne Gutenberg being found in the same register of the nobility liable to the wine-duty in the city of Strasbourg, in which Gutenberg's name also appears. The next document is so curious that an ample abstract of it cannot but be interesting.

It appears that he had contracted an engagement with Andrew Dritzehen, John Riffe, and Andrew Heilmann, to instruct them in the secrets of certain arts, and had entered into partnership with them for their better advantage. Andrew Dritzehen and Andrew Heilmann having called upon him one day, perceived that he was engaged in a wonderful and unknown art, the secret of which he was desirous of keeping to himself; that, moved by their importunities, he consented to enter into partnership with them for the term of five years, on two conditions,—first, that they should pay him the sum of 250 florins, 100 immediately, and the remainder at a certain fixed period; second, that if any one of the partners should die during the term of the copartnership, the survivors should pay to his heirs the sum of 100 florins, in consideration of which the effects should become the property of the surviving partners. Andrew Dritzehen died before the expiration of the period agreed on, being still indebted to Gutenberg in the sum of 85 florins. George and Nicholas, brothers of the deceased, demanded to be admitted to the partnership, and on refusal, brought an action against Gutenberg as principal partner. The magistrates gave judgment on the 12th of December 1439, relieving Gutenberg from the demand upon payment of the sum of 15 florins, being the difference of the sum of 100 florins, stipulated to be paid to the heirs of a deceasing partner, and the sum of 85 florins due to Gutenberg by Andrew on the original contract. The following evidence was produced on the trial :—

"Anna, the wife of John Schultheiss (*holzman, marchand de bois*), deposed, that on one occasion Nicholas Beildeck came to her house to Nicholas Dreizehen, her relation, and said to him, 'My Nicholas Dreizehen, Andrew Dreizehen, of happy memory, has placed four *stücke* (pages ?) in a press, which Gutenberg has desired that you will take away and them from one another put off, that no man may know what it may be, for he is not willing that any one should see.'

"Also John Schultheiss says, that Laurence Beildeck some time came to his house to Nicholas Dreizehen, when Andrew Dreizehen his brother was dead, and that the said Laurence Beildeck thus spoke to said Nicholas Dreizehen: 'Andrew Dreizehen, your brother, now happy, had four *stücke* lying underneath in a press. Therefore John Gutenberg desires you that you will take them therefrom and upon the presses take from one another so that no man can see what that is.'

"Also Conrad Sahspach deposed, that sometime Andrew Heilman came to him upon the Street of Merchants and said, 'Dear Conrad, as Andrew Dreizehen is departed, as you made the presses, and know about the matter, do you go thither, and take the *stücke* from the presses, and thoroughly separate (*zerlegen*) them from one another, so that no man may know what it is.'

"Laurence Beildeck says that he was sent by John Gutenberg to Nicholas Dreizehen, after the death of Andrew his brother, to say to him, 'That he the presses which he under his care has to no man should show; which also this witness did. And he further conversed with me, and said he should take so much trouble as to go to the presses, and with the two screws upon or from them so separate the *stücke* (*und die mit den zweyen würbelin uff den so vielen die stücke*) from one another, and these *stücke* he should then in the presses [*or*, on the presses] separate, so that thereafter no man can see nor understand.'

"The same witness also said that he knew well that Gutenberg, a little before the feast of the Nativity, had sent his servant to both Andrews to take away all *stücke*, which were broken up in his sight, that none of them might be found perfect. Moreover, after the death of Andrew, this witness was not ignorant that many were desirous of seeing the presses, and that Gutenberg had commanded that some one should be sent who might hinder any one from seeing the presses, and that his servant was sent to break them up.

"Also John Dunne, goldsmith, said, that three years or thereabouts previous he had received from Gutenberg about 300 florins for materials relating to printing."[1]

From this curious document may be learnt, that separate types were used; for if they were blocks arranged so as to print four pages, how could they be so pulled to pieces that no one should know what they were, or how could the abstraction of two screws cause them to fall to pieces? It appears that some sort of presses were used, and the transfers no longer taken by a burnisher or roller; and, lastly, that the art was still a great secret at the time when Koster was at the point of death. Hence it is manifest that the ingenuity of Gutenberg had made a vast advance from the rude methods of the time, and had in fact invented a new and hitherto unknown art.

These documents would be decisive in favour of Strasbourg as the place in which printing was invented, had it appeared that any effects were produced by this establishment. This, however, does not seem to have been the case, as Gutenberg and his successors make no mention of the fact, but, on the contrary, claim for themselves the production of the first book at Mentz. Indeed the partnership appears to have expired without any attempt at entering into fresh engagements; for, about the year 1450, Gutenberg returned to his native city with all his materials, without any opposition from his partner. In this place he entered into partnership with John Fust, a wealthy goldsmith and citizen, who engaged, upon being taught the secrets of the art (a fact that completely overthrows the fable of his having been one of Koster's workmen, and of his having stolen his types), and being admitted into a participation of the profits, to advance the necessary funds; and he did accordingly advance the considerable sum of 2020 florins. The new partnership immediately commenced operations, and hired a house called Zum Jungen, and took into their employ Peter Schœffer and others. Their subsequent operations we again find curiously chronicled in the records of another lawsuit,[2] in which Gutenberg was soon engaged with his new ally; for Fust, dissatisfied with their proceedings, sought to recover from Gutenberg money advanced, with interest, including 800 florins of the sum advanced in virtue of the deed of partnership. Gutenberg in defence alleged, that the 800 florins had not been paid at once, as stipulated; and that they had been expended in preparation for the work (apparently meaning thereby that this sum of money should have been paid down for his own use, in consideration of his communicating the secrets of his art, and that instead of so applying it to his private purposes, he had expended it for the joint benefit); whilst, as to the other sums, he offered to give an account of their appropriation, but denied that he was liable for the interest. The judges awarded that Gutenberg should pay the interest, as well as the part which his accounts showed he had applied to his individual use. This decision took place on the 6th of November 1455. Upon this, Fust obtained from the public notary the following document :—

"To the Glory of God, Amen. Be it known unto all those who shall see or hear read this instrument, that in the year of Our Lord 1455, third indiction, on Thursday the sixth day of November, the first year of the Pontificate of our very Holy Father the Pope Calixtus III., appeared here at Mayence, in the great parlour of the Bare-footed Friars, between eleven o'clock and mid-day, before me, the Notary, and the undersigned witnesses, the honourable and discrete person, James Fust, citizen of Mayence, who, in the name of his brother, John Fust, also present, has said and declared clearly, that on this same day, and at the present hour, and in the same parlour of the Bare-footed Friars, John Gutenberg should see and hear taken by John Fust an oath, conformable to the sentence pronounced between them. And this sentence read in the presence of the honourable Henry Gunter, Curé of St Christopher of Mayence, of Henry Keffer, and De Bechtoff de Hanaw, servant and valet of the said Gutenberg; John Fust, placing his hand upon the Holy Evangelists, has sworn between the hands of me, the Notary Public, conformable to the sentence pronounced, and to a letter which he has sent to me, and has taken the following oath, word for word: I, John Fust, have borrowed 1550 florins which I have transmitted to John Gutenberg, which have been employed for our common labour, and of which I have paid the rent and annual interest, of which I still owe a part. Reckoning, therefore, for each hundred florins borrowed, as above is recited, six florins per annum, I demand of him the repayment and the interest, conformably to the sentence pronounced; which I will prove in equity to be legal, in consequence of my claim upon the said John Gutenberg. In presence of the honourable Henry Gunter, of Henry Keffer, and of Bechtoff de Hanaw aforesaid, John Fust has demanded of me an authentic instrument, to serve him as much and as often as he hath need, in the faith of which I have signed this instrument, and have set thereto my seal."

---

[1] The original German text of these documents is given in M. Leon de Laborde's interesting tracts on the origin of printing.

[2] Wolfii *Monumenta Typographica*. Fournier, *Origine de l'Imprimerie*.

From this it would appear (indeed the mortgage of his printing materials to Fust, mentioned in this document, proves) that Gutenberg had expended the whole of his considerable private fortune in his experiments, and had fallen into the power of his more wealthy associate; for in consequence of this judgment, and owing probably to his being unable to repay the sums demanded, the whole of his materials, constructed with so much perseverance, fell into Fust's hands; for the initial letters used by Gutenberg and his partners, in works known and supposed to have been executed between 1450 and 1455, are likewise used by Fust and Schœffer in the Psalter of 1457 and 1459. After such a mortifying result of so many years' labour, it would have been no matter for wonder had Gutenberg abandoned the unprofitable pursuit. On the contrary, he appears to have immediately started anew with fresh vigour, and this time with success. Another legal document gives curious information.

"We, Henne (John) Genszfleisch de Sulgeloch, named Gudinburg, and Friele Genszfleisch, brothers, do affirm and publicly declare by these presents, and make known to all, that, with the advice and consent of our dear cousins, John, and Friele, and Pedirmann Genszfleisch, brothers, of Mentz, we have renounced and do renounce, by these presents, for us and for our heirs, simply, totally, and at once, without fraud or deceit, all the property which has passed by means of our sister Hebele, to the convent of St Claire of Mentz, in which she has become a nun, whether the said property has come to it on the part of our father Henne Genszfleisch, who gave it himself, or in whatsoever manner the property may have come to it, whether in grain, ready money, furniture, jewels, or whatever it may be, that the respectable nuns, the abbess, and sisters of the said convent, have received in common or individually, or other persons of the convent (have received), from the said Hebele, be it little or much; and we have promised and do promise, by these presents, in good faith, for us and for our heirs, that neither we, nor any person on our part, nor yet our said cousins, nor any of their heirs, nor any person on their part, shall either demand, gain, nor claim of the said convent, nor of the abbess, nor of the convent in general, nor of the persons who may be found therein individually, the said property, of whatever kind it may be, either wholly or in part, and that we will never demand it again, either through an ecclesiastical or civil court, or without the aid of the law; and that neither we nor our heirs will ever molest the said convent, either by words or deeds, either secretly or publicly, in any manner. And as to the books which I, the said Henne, have given to the library of the convent, they are to remain there always and for ever; and I, the said Henne, propose also to give in future, without disguise, to the library of the said convent, for the use of the present and future nuns, for their religious worship, either for reading or chaunting, or in whatever manner they may wish to make use of them according to the rules of their order, *all the books which I, the said Henne, have printed up to this hour, or which I shall hereafter print, in such quantities as they may wish to make use of;* and for this the said abbess, the successors and nuns of the said convent of St Claire, have declared and promised to acquit me and my heirs of the claim which my sister Hebele had to the sixty florins, which I and my said brother Friele had promised to pay and deliver to the said Hebele, as her portion and share arising from the house which Henne our father, assigned to him for his share, in virtue of the writings which were drawn up thereupon, without fraud or deceit. And in order that this may be observed by us and by our heirs, steadfastly and to its full extent, we have given the said nuns and their convent and order these present writings, sealed with our seals. Signed and delivered the year of the birth of J. C. 1459, on the day of St Margaret."

From this it will appear, that his new establishment had actually produced the long wished-for effect. He appears to have carried on the business ten years; for in 1465 he entered into the service of Elector Adolphus of Nassau, as one of his band of gentlemen pensioners, with a handsome salary, as appears from the letters-patent, dated the 17th January 1465, and finally abandoned the pursuit of an art which, though it caused him infinite trouble and vexation, has been more effectual in preserving his name and the memory of his acts, than all the warlike deeds and great achievements of his renowned master and all his house. Gutenberg died on the 24th of February 1468. His printing-office and materials had passed into the hands of Conrad Humery, syndic of Mentz, who had probably assisted him with money, and who appears to have been in some degree his partner. He afterwards sold them to Nicholas Bechtermunze of Elfield, whose works are greatly sought after by the curious, as they afford much proof, by collation, of the genuineness of the works attributed to his great predecessor.

There does not appear to be any record of the early life of JOHN FUST or PETER SCHŒFFER before their partnership with Gutenberg, save that the former was a wealthy goldsmith and an ingenious man, and that Schœffer, surnamed de Gernsheim, was a scribe. It is very likely that the combination of character and qualifications of these three men may afford a good clue to the wonderful taste and beauty which distinguish the works issued from their press, and consequently to the great general improvement of the art during their life. The ingenuity of Gutenberg would readily suggest a new and expeditious method of manufacturing types; the practical skill of Fust as a worker in metals (and the working in gold and silver had at that time attained a most extraordinary nicety and beauty), and his large pecuniary resources, would readily provide the necessary appliances, while the taste of Schœffer would give all possible grace and beauty to the new forms. For Schœffer, it must be recollected, was a scribe, one of the ancient and honourable craft whose occupation was destined to fall before the new art; a transcriber, perhaps an illuminator, of the manuscript works in use before printed books; and those who have had the happiness of viewing those exquisite specimens of skill which beguiled our ancestors into study and devotion (when will modern typography produce such feasts for mind, and eye, and imagination?) will readily conceive that Schœffer's eye was already schooled for the conception, and his hand for the execution, of all the beauty the trammels of a new art and limited skill would allow. Aided by his own taste and his partners' invention and wealth, Schœffer proceeded to a new enterprise, namely the *casting* of type. The entire conception and execution of this invention has been generally attributed and allowed to Schœffer. It seems most probable, however, that where three ingenious men are bound together by art and interest, no one of them can lay exclusive claim to any invention or undertaking executed in the workshops and for the mutual benefit of all. Allowing, therefore, to Schœffer the honour of having suggested some such plan, the other two may fairly put in a claim for their portion of the credit on the score of their suggestion and assistance; especially since Fust, as a worker in metals, would have been the party to engage workmen to elaborate the conceptions of his partners' brain. Accordingly the only evidence upon the subject appears to show that the partners had for some time practised a method of taking casts of types in moulds of plaster; for it must be remembered that the types of Gutenberg's earlier efforts, both at Strasbourg and at Mentz, were cut out of single pieces of wood or metal with infinite labour and imperfection. This method of casting, however, although a great improvement, was at best but a slow and tedious process. Almost every type cast would require a new mould; no skill or care could enable the workman to impress so small a thing as a type is at the face, yet so elongated in the shank, fully, freely, and steadily, into a soft material; and it would be necessary afterwards, under the most favourable circumstances, that the squareness and sharpness so indispensable in type should be given by another slow process; so that at best this advance was but an imperfect and tedious operation. Schœffer has therefore an undoubted claim to be considered as one of the three inventors of printing; for he it was who first suggested the cutting of punches, whereby not only might the most beautiful form of type the taste and skill of the artist could suggest be fairly stamped upon the matrix, but a degree of sharpness and finish quite unattainable in type cut in metal or wood could be given to the face; whilst to the shank, by the very same process by which the face was cast, the mould would give perfect sharpness and precision of angle. Add to this, that the punch being once approved of, could be kept ready to stamp a new matrix in precisely the same condition and form as the first, should that be worn out or mislaid, or make a duplicate should the demands of business require it. It is nevertheless rather singular, that the mould represented on the right side of the press of Ascensius, shortly after the time of Schœffer, should be precisely the same in form and manner of use as that of the present day. This was evidently an immense stride toward perfection; let Schœffer therefore take a place on the right hand of the inventor.

Whatever may have been the several shares of the masters in perfecting their art, their joint labours were effectual. The first productions of their press—passing over an *Alphabet*, the *Doctrinale* of Alexander Gallus, and a *Donatus*, which are of doubtful authenticity, and are merely block-books—were three editions of Donatus, the first *books* known to have been printed entirely with moveable types. In 1455 they printed the celebrated *Litteræ Indulgentiæ Nicolai V. Pont. Max.*, which is the first work,—it is only a single page,—printed with moveable types which is dated. In 1455, or thereabouts, for it has no date, they printed the famous *Biblia Latina Vulgata*, generally known as "the Mazarine Bible." It has no colophon or *Explicit*. And it should be noted, that there is no book known which bears the conjoint names of Gutenberg, Fust, and Schœffer, nor any which has the imprint of Gutenberg alone.

Within eighteen months of their separation from Gutenberg, Fust and Schœffer produced the celebrated Psalter. This was printed with large cut type. As it is impossible that a new fount could have been prepared, and so splendid a work printed, within that short space, it must be evident that the partners did great injustice to Gutenburg in suppresing his name from the colophon. This book was produced in the month of August 1457, and is the first book which bears the name of the place where it was printed, those of its printers, and the date of the year in which it was printed. This Psalter was reprinted in 1459, 1490, and 1502, and always in the same type, which, it is remarkable, was never used for any other work, probably because its great size made it unfit for any other works than those not intended for popular reading, but to lay on desks like our church Bibles. On the 16th of October 1459 Fust and Schœffer published the *Durandi Rationale Divinorum Officiorum*, with an entirely new fount of type; in 1460 the *Constitutiones Clementis V.*; and in 1462 the celebrated Latin Bible. In 1465 they printed *Cicero de Officiis*, in which occur the first printed Greek types. Fust enjoyed this successful and glorious practice of his art but ten short years; yet in this period what an immense advance from the misshapen and irregular lumps of their first efforts, ugly in themselves, and more ugly in their utter want of relative proportion and allignement, to the well-proportioned, evenly-standing type of the Bible! The plague carried him off in Paris about the year 1466, full of years, and perchance full of honours. Schœffer survived many years, and, in conjunction with Conrad Henlif, produced a great number of works. His name is found in the colophon of the fourth edition of the Bible of 1402, about which time he is supposed to have deceased. There are ten books which are known to have been printed by Fust and Schœffer conjointly. Schœffer continued to print during a period of thirty-five or thirty-six years after the death of Fust, and his productions are very numerous.

Were we to take tradition for our guide as regards the character of Fust, we should regard him as a conjuror and an adept in the black art. The popular story (and many "grave and discrete old men" have given credit to the tale) runs, that having kept these proceedings profoundly secret, as soon as their Bible was finished, Fust transferred himself to Paris with many copies of the new work, and palmed them upon the learned as manuscripts—to which, as they were printed on vellum, in a type bearing much resemblance to the written books of the period, and the vignettes and initial letters were splendidly illuminated, they were not very dissimilar; that some eager scholar or devotee became the possessor of the first copy, supposing it to be a rare chance, at the moderate price of four or five hundred crowns; that as he brought the work into the market, the price fell rapidly to sixty, and then to thirty crowns, by which time the extraordinary glut produced suspicion, and Fust was accused of multiplying Holy Writ by the aid of the Devil, and was accordingly persecuted by the priesthood, whilst the laity, looking to their temporal interests, prosecuted him for his inroad into their pockets; and that from these things Fust was obliged to quit Paris precipitately.

Having thus given a sketch of the origin and history of the art of printing, a brief account of the works issued by the illustrious triumvirate will not only be proper here, but will give the general reader a better idea of the astonishing perfection to which the art rose under the taste and genius of its inventors. As before remarked, there is not a single work of Gutenberg which bears his name; yet there are several which bear such internal evidences that the literati of all parties and opinions are unanimous in attributing them to his press.

Of these works, Dr Dibdin, the well-known bibliographer, gives the following account:—

"First, as to the *character of the type* used by the early Mentz printers. This appears to have been uniformly what is called *Gothic;* and if we except the varieties of the larger type (from three-eighths to two-eighths or to a quarter of an inch), which appear in the Psalters of 1457, 1459, and 1490 (the type common to most works executed about the same period), we shall observe three distinct sets or forms of letters used in the printing-office of Faust and Schoiffher. Of these three typographical characters, two only (if we except the one with which the Bible of 1455 was executed) are visible in the publications which appear to have been printed in the lifetime of Faust; that is to say, the larger Gothic used in the Bible of 1462, and the smaller Gothic in the *Offices* of Cicero, of the dates of 1465 and 1466. These appeared united, the former, for the first time, in the *Constitutions of Pope Clement V.*, of the date of 1460. Schoiffher introduced a type of an intermediate size, which may be seen, among other works, in the *Rudi-*

ments of Grammar of 1468, and in the *Decretals of Pope Gregory the Ninth*, of the date of 1479. This intermediate type is of a narrower form, and prints very closely. Of the three types here mentioned, the largest is undoubtedly of the handsomest dimensions; but they all partake of the *Secretary Gothic*, and may be said to be the model of that peculiar character which was adopted by the early Leipsic printers, Thanner and Boëttiger, and was more especially used by John Schoiffher and the other German printers for nearly the whole of the sixteenth century. Shew me Lisardo, one book, nay, one leaf only, printed in the *Roman type*, in the colophon of which the name of Faust or of Peter Schoiffher appears, and you shall immediately have the amount of the balance in my favour, at my banker's, be it great or small, be it L.200 or L.20, for such a precious and unheard-of curiosity.

"We shall now, in the second place, say a few words as to the *character of the printing*, or of the *mechanical skill*, of the early Mentz press. There can be but one opinion upon this point. Everything is perfect of the kind, the paper, the ink, and the register, or regularity of setting up the page. The Bible of the supposed date of 1455 is quite a miracle in this way;[1] but the Psalters are not less miraculous, nor is less praise due to the *Constitutions of Pope Clement V.*, of the date of 1460, and the *Bible* of 1462; while the *Durandus*, of the earlier date of 1459, exhibiting the first specimen of the smallest letter, strikes one as among the most marvellous monuments extant of the perfection of early typography. Almost all the known works before the year 1462 are printed *upon vellum*, doubtless because they ventured upon limited impressions; and even of the Bible of 1462 more copies have been described upon vellum than upon paper. Upon the whole, the vellum used by Faust and Schoiffher, although inferior to the Venetian, is exceedingly good, being generally both white and substantial.

"In the third place, let us notice the nature or character of the works which have issued from the press of Faust and Schoiffher. Whatever may be our partiality towards that establishment from which the public were first gratified with the sight of a printed book, candour obliges us to confess that the fathers of printing were not fortunate, upon the whole, in the choice of books which issued from their press.

"In the fourth place (for I told you I should be somewhat tautologous), consider what is the typographical appearance of those books which Gutenberg is really supposed to have executed. It is quite unique. A little barbarous, and certainly wholly dissimilar from any thing we observe in other contemporaneous productions of the Mentz press. You will please to understand that I think very doubtfully of the *Donatuses*, which are considered to have been printed by him; as well as of the *Speculum Sacerdotum*, and *Celebratio Missarum*; concluding the *Catholicon* of 1460, and the *Vocabularies* of 1467 and 1469, to be the more genuine productions of his press, or of the types used by him. Is it not surprising, I ask, that these works are executed in types quite different from anything we observe in the Mentz productions? and this from a man who is considered as the parent of printing in that city. No wonder, if they *be* the actual productions of Gutenberg, that Faust and Schoiffher thought so meanly of his talents, and that on a dissolution of partnership they adopted a different and a very superior character."

In confirmation of these remarks of the learned bibliographer, we shall here insert a specimen of Gutenberg's *Balbus de Janua*, which will also be a curious illustration of ancient art. Notwithstanding the appearance of these types, the reader is assured that the original is really printed from separate pieces of metal.[2]

Dr Horne, in the appendix to his *Introduction to Bibliography*, says of the Psalter, "This precious work, as Santander justly calls it, is one of the most known among early printed books, from the various and correct descriptions of it which have been given by different bibliographers. Until the discovery of Pope Nicholas' *Literæ Indulgentiarum*, this was supposed to be the very first article ever printed with a date affixed; the book is executed on vellum, and of such extreme rarity that not more than six or seven copies are known to be in existence; all of which, however, differ from each other in some respect or other. The most perfect copy known is that in the imperial library at Vienna; it comprises 175 leaves, of which the Psalter occupies the 135 first and the recto of the 136th. The remainder is appropriated to the litany, prayers, responses, vigils, &c. The psalms are executed in larger characters than the hymns, similar to those used for missals prior to the invention of printing; but all are distinguished for their uncommon blackness. The capital letters, 288 in number, are cut on wood with a degree of delicacy and boldness which are truly surprising; the largest of these, the initial letters of the psalms, which are black, red, and blue, must (as Lichtenberger has remarked) have passed *three times* through the press. Copies are now in the Queen's library at Windsor, and in that of Earl Spencer at Spencer House." A facsimile of the initial B, and a portion of the first verse of this beautiful book, and of the colophon at the end, will be found in Plate III.

The extraordinary praise awarded by these eminent bibliomaniacs to the first productions of the Mentz press may perchance excite in the minds of the more sober public a suspicion that these writers have been led away by their enthusiasm beyond the limits of matter-of-fact truth, and have seen merit in defects, beauty in deformity, and lustre in antiquity. Assuredly, nevertheless, such is by no means the case; and the happy individual who gains access to the *chef-d'œuvres* of Fust and Schœffer will return from the inspection a wiser man; for the beauty of these works is inconceivable. England fortunately possesses several of these treasures of art, there being copies of the Bible of the supposed date of 1450–55 in the Royal Library, in the Bodleian, and in those of Earl Spencer and Henry Perkins, Esq.; whilst of the six known copies of the Psalter of 1457, two are in England, namely, one at Windsor, and one in the possession of Lord Spencer. Of the Latin Bible of Fust and Schœffer, 1462 (the first bearing date), there are copies *on vellum* at Blenheim, in the libraries of Lord Spencer, the Earl of Jersey, one formerly belonging to Sir M. Sykes, in the British Museum, and in the Bodleian (imperfect). Copies *on paper* are rarer still, there being but three in this country, viz., those in the Royal Library and the British Museum, and one lately in the possession of Mr Willett.

Apparently, in retaliation for the injustice done to Gutenberg by his partners in depriving him of any share of the honour of producing the Psalter of 1457, which, as before stated, must be the joint production of all three, although it was not finished until after the secession of Gutenberg, bibliographers have generally agreed in attributing the printing of the Bible of 1450-55 to Gutenberg alone, when it is equally manifest that Fust and Schœffer had as much claim to the honour as their coadjutor. It is an exceedingly beautiful book, in two very large folio volumes, in two columns, containing from forty-one to forty-three lines each, in very large well-cut types. It consists of six hundred and forty-one leaves; it has no title, paging, signatures, or catch-words; the initial letters are not printed, but painted in by illuminators, and the initial letters of each verse of the psalms are painted alternately red and black, by way of guide to the priests in their alternate reading. From the lustre and blackness of the ink, its evenness of colour, and beautiful execution, it is a very superb book; but it is nevertheless surpassed by the Fust and Schœffer edition of 1462, when they had attained greater experience in the practice of the art. By far the choicest, however, of these *editiones principes* is the Mentz Psalter or *Codex Psalmorum* before mentioned, the initial B and first few lines of which form part of Plate III. Dr Horne says that the six known copies of this edition differ from each other in some respects, and proceeds to give some particulars in which variations are found; but by collating the copies in the Royal Library, that at Windsor, and that at the British Museum, it will be found that, although bearing the same date, they are in fact three distinct editions. It would have excited no surprise had it been found that the printed ornaments differed, as nothing would be more easy than to change the colours with which the different blocks were worked; and in fact in the Museum copy the initial B is printed in a bright blue, and the scroll-work is red; but the text varies in such a manner that there can be no doubt of their perfect distinctness. Taking the first six lines, the following are the last words of each line:—

---

[1] This is even sober praise. The mechanism of the press-work, and appearance of the ink, beautiful, regular, and glossy as the whole appears, does not strike one with more astonishment than the manufacture of the paper. "Charta," says Tungendres, "ejusdem est crassitudinis, qualem illo tempore libris imprimendis consumere mos fuit." And again, "Charta ob ejus densitatem atque spissitudinem haud ingratam ubique se maxime commendat." (*Disq. de Not. Charact. Libror.* p. 27, p. 46.) And see Meerman's testimony in favour of the paper of the Soubiaco press, *Orig. Typog.* vol. i. p. 9, note.

[2] The initial A is illuminated in a very brilliant blue. The reader who is desirous of obtaining the full effect of this specimen can fill up the printed outline in water-colour.

Windsor.	Earl Spencer.	British Museum.
. . . . abiit	. . . . qui non	. . . qui ═══

It must also be noted that in the Windsor copy each line is "justified out," which is not the case in Earl Spencer's copy; and that in the Museum copy the page commences with rubrical matter, which is continued down the two first lines of text, which are shortened. The difference is effected by variations in the contractions of many of the words. The book[2] is a very large folio, on vellum, consisting of about a hundred and thirty leaves, printed on both sides. There are generally twenty-three lines in a page, in Gothic type. Every psalm begins with a splendid initial letter, about two thirds of the size of the B, *printed* in two colours in almost every case. Occasionally, however, this appears to have been neglected, and then the letter is painted in by the illuminator, but *not* in imitation of the printed letters. The initials consist (like the B) of a bold character, of Gothic cut, surrounded by a scroll, which is sometimes of great length, that of the B extending from the top to the bottom of the page. The same wooden block is used as often as the letter occurs, but it is not always in the same colours. Moreover, every *verse* commences with a smaller initial printed in a red colour, in the same manner as the s in the specimen. Nor is this work destitute of the embellishments of the illuminator; for at the commencement of every psalm is a rubric, painted in a most brilliant red, in a smaller letter, of precisely the same character as the text, and also the music of the chant, with the words underneath it painted in black. The initial letters of both are splendidly illuminated in various colours. The paint is used in such profusion that the letters are absolutely in relief, often to the extent of one sixteenth of an inch; and besides these, the letter following the grand initial has a broad bar painted down it, and very frequently the first letter after the pauses indicated in our authorized version by a colon is illuminated in a similar manner. One page is particularly splendid; it consists of short verses, in which the first words are constantly repeated. It commences with a grand initial, and there are twenty-two smaller initials to the verses; the second letter of the first verse, and the first letter after every pause (twenty-three in number), having the broad illuminated bar. Wherever the psalm commences too near the bottom to allow of the full exuberance of the scroll, a piece of paper appears to have been laid over a portion of the cut, to prevent the impression from appearing; and in one psalm where the chant is of unusual length, the lower part of the initial O, and a corresponding portion of the scroll, are thus suppressed; the music being illuminated in its place, and the scroll continued below it. Sometimes the illuminator has omitted to add his initial letter; and in this copy the double device is omitted. The accuracy with which the coloured blocks are printed within the text and within each other is perfectly astonishing. From this description it may be conceived how very superb is the *first* book ever printed, the date, and place, and artist, of which can be accurately ascertained. Dr Dibdin in the *Bibliotheca Spenceriana*, Mr Savage in his work on *Decorative Printing*, Dr Horne, whose wood-block is not coloured, and several other writers, have given fac-similes of the same copy (Lord Spencer's), which, however, all differ from one another. The lines given in the specimen in Plate III. are copied from Dibdin, whose initial B does not accord with that of the Windsor copy; the B here given is very accurate, and the colours are as similar as possible to the latter copy, but the colour of the scroll in the original seems somewhat faded.

Early printers.

The capture of the city of Mentz by Count Adolphus of Nassau in the year 1462 had the effect of interrupting the labours of Fust and Schœffer; and moreover the distracted state of the city enabled, perhaps compelled, the workmen initiated in the mysteries of the art to flee into the neighbouring states, and thus spread its practice over the whole civilized globe. Such, indeed, was the fame it had already acquired, and such the idea entertained of its importance, that every community with the slightest pretensions to literature appears to have sought a knowledge of it with the greatest avidity. Thus, within six years of the publication of the Psalter, it had spread to several cities having some connection with Mentz, and within fifteen years to almost every town of consideration in Christian Europe. A chronological list of the cities which first seized upon the invention would be greatly too long for this article; it may be interesting, however, to extract a few of the principal, with a notice of such printers as are remarkable either for the beauty or the scarcity of their works. The reader is not to suppose that all, or indeed any great number of these, learned the practice of the art under the tuition of the first masters. A few are known to have been pupils of the inventors, and it is probable that many others of them were so; but the majority, in all likelihood, were men of learning, enterprise, or capital, who derived their typographical knowledge from such facts as had transpired, or from inferior

---

[1] It is desirable that the subsequent pages of the several editions should be collated. If similar variations should be found throughout, it will give rise to much speculation. If they are found to be identical, the suspicion will arise, that the first and last pages were intentionally varied, perhaps for the purpose of misleading, and the story of these first books having been offered for sale as manuscripts will receive some countenance.

[2] The copy described is that at Windsor; the illuminations, no doubt, vary in every copy.

workmen of Fust and Schœffer or Gutenberg, supplying deficiencies by their own ingenuity.

Strasbourg. Mentelin. Some writers have claimed for Mentelin the invention of printing, representing that Gutenberg was his servant, without, however, showing the slightest ground for their assertions; but others, more reasonable, say that he was acquainted with Gutenberg, and instructed by him, and that on the latter's quitting Strasbourg he established a printing-office, and carried on the business successfully. Mentelin most probably printed about the year 1458. His type is rude and inelegant. The only book bearing his name is Beauvais' *Speculum Historiale*, of date 1473. Schœpflin says, that he, as well as Fust and Schœffer at Mentz, printed 300 sheets per day.

In 1461. *Bamberg.* Albert Pfister. He printed a collection of *Fables*, of date 1461. This book is excessively rare; it is printed with cast metal type, and is illustrated with 101 wood-cuts, in much the same style as the old *Biblia Pauperum.* All his other works are printed in the same type.

1465. *Subiaco* and *Rome.* Schweynheym and Pannartz. Their known works are, a *Donatus*, without date; Lactantius, 1465; St Augustin on *the City of God*, 1467; Cicero *de Oratore*, without date; and the *Commentary of De Lyra on the Bible*, 1471, all in folio. These works were printed in a new letter, very closely resembling the type now in use called *Roman*, and of which they were the introducers. In *De Lyra* are the earliest specimens of Greek types worthy of the name; some few letters appear in the *Cicero de Officiis* printed at Mentz, but so wretchedly imperfect that they are unworthy of mention. It is curious that the Greek fount of Schweynheym and Pannartz at Subiaco was evidently very small; but upon their removal to Rome they cast a much larger fount. The cut and appearance of this Greek is more than respectable. There is a very curious petition from them to the pope, praying for assistance on the ground that they had entirely ruined themselves by printing *De Lyra*, for which there was no sale, and representing that they had on their hands no less than eleven hundred folio volumes of that work. Subiaco is the first place in Italy in which printing was practised. At Rome Ulric Han and Lignamine were contemporaries. Their works, particularly those of Han, are excessively rare.

1467. *Elfield.* Henry and Nicholas Bechtermunze. They purchased from Conrad Humery the types and materials of Gutenberg. Their works are not at all remarkable for beauty, but are very rare, and much sought for as affording evidence of Gutenberg's works.

1467. *Cologne.* Ulric Zell. His type is Gothic, and of no beauty; but his works are rare.

1468. *Augsburg.* Ginther Zainer printed the first book in Germany with Roman type.

1469. *Venice.* John de Spira, whose works are of the utmost beauty. His edition of Pliny is splendid, and enormous sums have been given for those printed in vellum. He did not use Greek characters; but Greek passages are composed in Roman types. In the same city, at the same time, printed Nicholas Jenson, whose works are equal, if not superior, to those of Spira; they are not so rare, but are almost equally sought after. A copy of his folio Latin Bible of 1479, printed in Gothic type, was sold at Mr Edwards' sale for L.115. 10s. Venice was also the residence of Christopher Valdarfar, whose works gave rise to a most extraordinary event connected with bibliography, viz. the sale of the first edition of *Il Decamerone di Boccaccio*, printed by him in 1471. For many years it had been known that a single copy of this work was in existence, and the most devoted bibliomaniacs had used their utmost endeavours to discover it, but in vain. At length, about 1740, an ancestor of the Duke of Roxburghe obtained possession of it for the sum of one hundred guineas. In lapse of time it became the property of John duke of Roxburghe, the accomplished, indefatigable, and undaunted bibliomaniac, after whose death his gorgeous library was dispersed by the auctioneer in the year 1811. The interest excited amongst the learned by this sale was intense. It was known that the collection contained the most superb specimens of every kind of ancient lore; that the illuminated manuscripts were the most brilliant, the ballads the most obscure, the *editiones principes* the most complete that the world could produce; that the rarest Caxtons, the finest Pynsons, and grandest specimens of the foreign printers, were here to be found; above all, it was rumoured that a mysterious edition of Boccaccio's Decameron would become a bone of contention amongst the noblest of the literati. The public, learned and unlearned, were infected with the mania, and the daily papers teemed with notices of the sale. At length the important day arrived, the 17th of June 1811. St James' Square was the place. Mr Evans presided. The room was crowded; Earl Spencer, the Marquis of Blandford, the Duke of Devonshire, and an agent of Napoleon, were amongst the most prominent. The book was a small folio, in faded yellow morocco binding, black-letter. "Silence followed his (Mr Evans') address," says Dibdin. "On his right hand, standing against the wall, stood Earl Spencer: a little lower down, and standing at right angles with his lordship, appeared the Marquis of Blandford. The duke, I believe, was not then present; but my Lord Althorpe stood a little backward, to the right of his father Earl Spencer. Such was 'the ground taken up' by the adverse hosts. The honour of firing the first shot was due to a gentleman of Shropshire, unused to this species of warfare, and who seemed to recoil from the reverberation of the report himself had made. 'One hundred guineas,' he exclaimed. Again a pause ensued; but anon the biddings rose rapidly to five hundred guineas. Hitherto, however, it was manifest that the firing was but masked and desultory. At length all random shots ceased, and the champions before named stood gallantly up to each other, resolving not to flinch from a trial of their respective strengths. 'A thousand guineas' were bid by Earl Spencer; to which the marquis added 'ten.' You might have heard a pin drop. All eyes were turned; all breathing well nigh stopped. Every sword was put home within its scabbard, and not a piece of steel was seen to move or to glitter save that which each of these champions brandished in his valorous hand. See, see; they parry, they lunge, they hit; yet their strength is undiminished, and no thought of yielding is entertained by either. 'Two thousand pounds' are offered by the marquis. Then it was that Earl Spencer, as a prudent general, began to think of an useless effusion of blood and expenditure of ammunition, seeing that his adversary was as resolute and fresh as at the onset. For a quarter of a minute he paused, when my Lord Althorpe advanced one step forward, as if to supply his father with another spear for the purpose of renewing the contest. His countenance was marked with a fixed determination to gain the prize, if prudence in its most commanding form, and with a frown of unusual intensity of expression, had not bade him desist. The father and son for a few seconds converse apart; and the biddings are resumed. 'Two thousand two hundred and fifty pounds,' said Lord Spencer. The spectators are now absolutely electrified. The marquis quietly adds his usual 'ten,' and there is an end of the contest. Mr Evans, ere his hammer fell, made a due pause, and, indeed, as if by something preternatural, the ebony instrument seemed itself to be charmed or suspended 'in mid air.' However, at length down dropped the hammer, and, as Lisardo has not merely poetically expressed himself, 'the echo' of the sound of that fallen hammer 'was heard in the libraries of Rome, of Milan, and Saint Mark.' Not the least surprising incident of this extraordinary sale is, that the marquis already possessed a copy of the work, which wanted a few leaves at the end; he therefore paid this enormous sum for the honour of possessing a few pages. The prize of this contest is now in the possession of Earl Spencer."

1469. *Milan.* Lavagna. In 1476 Dionysius Palavasinus printed the Greek Grammar of Constantine Lascaris, in quarto, which is the first book printed entirely in Greek. The first printing in Hebrew characters was performed at Soncino, in the duchy of Milan, in 1482.

1470. *Paris.* Ulricus Gering, M. Crantz, and M. Friburger.

1471. *Florence.* Bernard Cennini. In 1488 Demetrius of Crete printed the first edition of Homer's works, in most beautiful Greek.

1474. *Basle.* Bernardus Richel.

1474. *Valencia.* Alonzo Fernandes de Cordova.

1474. *Louvain.* Joannes de Westphalia.

1474. *Westminster.* William Caxton, the Game of Chess.

1475. *Lubeck.* Lucas Brandis.

1476. *Antwerp.* Thierry Martins of Alost.

1476. *Pilsen* in Bohemia. *Statuta Synodalia Pragensia;* printer's name not known.

1476. *Delft.* Maurice Yemantz.

1478. *Geneva.* Adam Steinschawer.

1478. *Oxford.* Theodericus Rood.

1480. *St Albans. Laurentii Guillielmi de Saona Rhetorica Nova;* printer's name not known.

1482. *Vienna.* John Winterburg.

1483. *Stockholm.* Johannes Snell.

1483. *Harlem.* *Formulæ Novitiorum,* by Johannes Andriesson. This is the earliest book printed at Harlem *with a date.* In giving this as the first work *known* to be printed at Harlem, the claims of Koster, his grandsons and successors, must, of course, be reserved.

1493. *Copenhagen.* Gothofridus de Ghemen.

1500. *Cracow.* Joannes Haller.

1500. *Munich.* Joannes Schobzer.

1500. *Amsterdam.* D. Pietersoen.

1507. *Edinburgh.* A Latin Breviary; no printer's name. From a patent of James IV. it appears that the first printing press was established at Edinburgh in 1507. From the style and types, it is probable that they were imported from France.

1551. *Dublin.* Ireland was apparently the last country in Europe into which printing was introduced. The first book printed is a black-letter edition of the Book of Common Prayer, printed by Humphrey Powell.

1569. *Mexico.* Antonio Spinoza, *Vocabulario en Lengua Castellana y Mexicana.*

1639. *United States,* at the town of Cambridge. Printer Stephen Daye.

It was the custom of the early printers to distinguish their books by the most fantastic devices; and by these their works may be readily recognised. Many of them were of exceeding beauty, and all the skill and appliances of their art were employed to render them striking; they are really an ornament to their works. The invention of these has been ascribed to Aldus; but the very first printers, Fust and Schœffer, used each for himself, yet conjoined, devices of rare excellence. Their celebrated Bible is adorned with one which is well worthy of being adopted as the arms of the art and mystery of printing. This is given in the plate of illustrations with those of Caxton, Wynkyn de Worde, and Pierre Regnault, who, with his brother, printed the first English Testament at Paris.

Our chronological arrangement has precluded us from mentioning some of the most skilful typographers. Their works, however, are so numerous, and their efforts so well known, as to render it unnecessary to do more than mention their names. Such men as the Aldi,[1] Frobenius, Plantinus, Operinus, the Stephani, the Elzeviri, the Gryphii, the Giunti, the Moreti, and hosts of peers, have universal fame. The printing-office of Plantinus, in the Place Vendredi, at Antwerp, exists in its full integrity, and in the possession and use of his descendants the Moreti; the same presses, the same types, with the addition of every improvement modern skill has effected, are still in use, and an inspection of these singular relics of olden art will well repay the investigation of the curious.

The First Presses.

Of the mechanical means by which these beautiful impressions of the old printers were produced there is little or no record; but it is quite evident that they must have been effected by some more skilful process than mere manipulation, that is, than the appliance of a burnisher, as is evident in the first wood-cuts, or of a roller, or superficial pressure applied immediately by hand. It is very probable that one of the difficulties which Gutenberg found insuperable at Strasbourg, was the construction of a machine of sufficient power to take impressions of the types or blocks then employed; nor is it at all wonderful that the many years he resided at that city were insufficient to produce the requisite means; for, with cutting type, forming his *screws,* inventing and making ink, and the means of applying his ink when made, his time must have been amply occupied. Moreover, the construction of a press would require a versatile genius, and excellent mechanical skill, not to be looked for in one man. But upon his junction with Fust and Schœffer, the gold of the former, and the invention of all the three, would soon supply the defect; and, for aught that appears to the contrary, the press used in their office differed in no essential point from those in use until the improvements of Blaew in 1600–20. Fortunately, amongst the singular devices with which it pleased the earlier printers to distinguish their works, Badius Ascensius of Lyons (1495–1535) chose the press; and there are cuts of various sizes on the title-pages of his works. It appears from these, that, like that of Gutenberg, they could print only four pages at a time, and that at two pulls; and when it is stated that the table and tympan ran in, and that the platten was brought down by a powerful screw, by means of a lever inserted into the spindle, the professional reader will easily recognise the wooden presses laid up in ordinary in many old London houses.

The colour which the earliest typographers used was probably made according to the style of work in hand. The earliest copies of the *Speculum* and *Biblia Pauperum* were printed in a brown colour, of which raw umber is the principal ingredient. It appears to have been well ground and thin. It was, most likely, of the same tint as the old drawings of the same subjects, and would be better adapted for the filling up in various colours, as appears to have been the practice, than a black and harsh outline of ink. Fust and Schœffer, however, introduced, and their followers adopted, black ink, and were so skilful in compounding it that their works present a depth and richness of colour which excites the envy of the moderns; nor has it turned brown, or rendered the surrounding paper in the slightest degree dingy. From the above-mentioned colophons we have also the method of applying it to the types. This was by means of balls of skin stuffed with wool, in every respect the same as those used fifty years ago. The ink was laid in some thickness on a corner of a stone slab, and taken thence in small quantities and ground by a muller, and thence again taken by the balls and applied to the types. The types appear to have been disposed in cases very much the same as ours. The composing-stick differs somewhat, but cannot now be very clearly made out. The different operations of casting the type, composing, reading, and working, are mostly represented in the same apartment; but, it is probable, more for the sake of pictorial unity, than because such was really the custom. There must have been many workmen engaged in most of the old establishments; and they well knew the value of cleanliness, which is unattainable where all the operations are carried on together.

---

[1] It should be mentioned that Aldus Manutius invented the beautiful character of type called *Italic* at the end of the fifteenth century. The first book printed with it is a Virgil, 1501.

Introduction into England.

As the invention of printing has itself become matter of serious controversy amongst the learned of all countries, its introduction into England has not been suffered to pass without an attempt of the novelty-seekers to overturn the received opinion on the subject, and to give to another the laurel of a public benefactor, torn from him to whom the general voice had for two centuries allotted it. Fortunately, the quarrel is divested of one of the great difficulties of the continental, inasmuch as there does not appear to be any vestige of an art in any degree similar (such as block-printing) having been practised prior to the introduction of type-printing; the art, when it was brought over, being in a state somewhat approaching maturity. This controversy concerns the claims of William Caxton and Frederic Corsellis to the introduction of the knowledge of the art, and the printing of the first book, in this country.

The general and original belief is that Caxton, who for thirty years resided in the Low Countries, under the reign of Charles the Bold, and who had taken every opportunity of learning the new art, and had availed himself of the capture of Mentz to secure one of the fugitive workmen of Fust and Schœffer, established a printing-office at Cologne, where he printed the French original and his own translation of the *Recuyell of the Historyes of Troy;* that whilst at Cologne he became acquainted with Wynkyn de Worde, Theoderick Rood, both foreigners, and Thomas Hunte his countryman, who all subsequently became printers in England; that he afterwards transferred his materials to England; that Wynkyn de Worde came over with him, and probably was the superintendent of his printing establishment; that his first press was established at Westminster, perhaps in one of the chapels attached to the abbey, and certainly under the protection of the abbot; and that he there produced the first book printed in England, the *Game of Chess*, which was completed on the last day of March 1474.

The correctness of these facts is not matter of dispute, all writers agreeing that Caxton did so set up his press at Westminster, and print his *Game of Chess* in 1474; but it has been asserted that Caxton was not the first printer, nor his book the first book printed, in this country. Neither does the controversy rest upon the contradictory statements of many writers, for all authors of the same and succeeding period agree in ascribing the honour to Caxton; and when, in 1642, a dispute arose between the Stationers' Company and certain persons who printed by virtue of a patent from the crown, concerning the validity of this patent, a committee was appointed, who heard evidence for and against the petitioners, and throughout the proceedings Caxton was acknowledged as incontestibly the first printer in England. Thus Caxton seemed to be established as the first English typographer, when, soon after the Restoration, a quarto volume of forty-one leaves was discovered in the library at Cambridge, bearing the title of *Exposicio Sancti Jeronymi in Simbolum Apostolorum ad Papam Laurentium,* and at the end, "Explicit Exposicio Sancti Jeronymi in Simbolo Apostolorum ad papam Laurentium, Oxonie Et finita, Anno Domini M.CCCC.LXVIII. *xvii.* die decembris." Upon the production of this book the claim for priority of printing was set up for Oxford. In the year 1644 Richard Atkyns, who then enjoyed a patent from the crown, and whose claims consequently brought him into collision with the Stationers' Company, and who was desirous of establishing the prerogative of the sovereign, published a thin quarto work, entitled *The Original and Growth of Printing, collected out of the History and the Records of the Kingdome; wherein is also demonstrated that Printing appertaineth to the Prerogative Royal, and is a Flower of the Crown of England.* The book was published "*by order and appointment of the Right Hon. Mr Secretary Morrice.*" In support of this proposition Atkyns asserted that he had received from an anonymous friend a copy of a manuscript discovered at Lambeth Palace, amongst the archiepiscopal archives. The following is an abstract of this document. "Thomas Bouchier, archbishop of Canterbury, earnestly moved the king, Henry VI. to use all possible means to procure a *printing* mold, to which the king willingly assented, and appropriated to the undertaking the sum of 1500 merks, of which sum Bouchier contributed 300. Mr Turnour, the king's master of the robes, was the person selected to manage the business; and he, taking with him Mr William Caxton, proceeded to Harlem in Holland, where John Guthenberg had recently invented the art, and was himself personally at work; their design being to give a considerable sum to any person who should draw away one of Guthenberg's workmen. With some difficulty they succeeded in purloining one of the under workmen, Frederic Corsellis; and it not being prudent to set him to work in London, he was sent under a guard to Oxford, and there closely watched until he had made good his promise of teaching the secrets of the art. Printing was therefore practised in England before France, Italy, or Germany, which claims priority of Harlem itself, though it is known to be otherwise, that city gaining the art from the brother of one of the workmen, who had learned it at home of his brother, and afterwards set up for himself at Mentz." The *Exposicio* is asserted by inference to be the work of Corsellis. That this document is a forgery may be safely assumed; because of the more than unsatisfactory manner in which it is said to have been obtained; because no one ever saw this copy; because no one, except the unknown, ever saw the original, for it is not amongst the archives nor in the library of Lambeth Palace, nor was it when the Earl of Pembroke made diligent search for it in 17(   ), nor was it found when the manuscripts, books, and muniments were moved into a new building; because Caxton himself, who took so important a share in the alleged abduction of the workman, states that twelve years afterwards he was diligently engaged in learning the art at Strasbourg, and repeatedly ascribes the invention to Gutenberg, "at Mogunce in Almayne;" because, when three years afterwards the Stationers' Company instituted legal proceedings against the University of Cambridge, to restrain them from printing, this document was rejected, as resting only on Atkyns' authority; because Archbishop Parker, in his account of Bourchier, mentions the invention of printing at Mentz, but makes no claim for his having introduced it into England, and Godwin, *de Præsulibus Angliæ*, says that Bourchier, during his primacy of thirty-two years, did nothing remarkable, save giving L.120 for poor scholars, and some books to the university, and that he minutely examined two registers of his proceedings during this term, without making any mention of his having found therein any record of so remarkable a transaction; because, since these transactions must have taken place before 1459, Henry VI. was at that time struggling fearfully for his throne and life, Edward IV. being crowned in that year; from internal evidence of the document itself, for, not to mention the weak evidence for the city of Harlem, it is quite certain that Gutenberg never printed there, and by Junius the theft is ascribed to John Fust, who certainly was a rich goldsmith of Mentz; whereupon Meerman, finding these statements at variance with possibility, boldly invents another theory, making the sufferers Koster's grandsons, who never printed, as far as is known, and the robber Corsellis himself; and, lastly, because six years elapsed between this asserted introduction and the publication of his *Exposicio*, and eleven years between this and any other publication from any Oxford press.

Although these facts entirely confute the pretensions of Corsellis, there nevertheless remains the book itself, and unless some evidence can be produced, Oxford will still maintain the distinction of having printed the earliest book in England. Some of the most learned bibliographers entirely refuse their assent to the genuineness of the book. Middleton asserts that there must be an error of an x in the imprint, and produces many remarkable instances of similar typographical errors. This, however, is mere assertion; and, as in the Lambeth record, the best evidence is to be sought in the production itself; accordingly the work is printed with *cast* metal types, which are not proved to have been used by Koster at all, that art being invented by Gutenberg, Fust, and Schœffer at Mayence. The letter is of very elegant cut, the pages regular, and the whole work has the appearance of having been executed at a considerably advanced era of the art. Another and a good argument is, that the work has signatures, or marks for the binder, at the foot of the page, which were not used on the Continent before 1472, by John Koelhoff at Cologne. The evidence in favour of Caxton is direct and strong; the date of the Oxford book is contradicted by internal evidence, and discredited by the story set up in its support; there seems, therefore, no sufficient ground for withdrawing from Caxton the fame of being the introducer of printing into England.

Caxton.

William Caxton was born about the year 1412, in the Weald of Kent. His father was a wealthy merchant, trading in wool. He was brought up to the business of a mercer, and conducted himself so much to his master's satisfaction, that on his death he bequeathed him the then considerable sum of twenty marks. Caxton then proceeded, probably as the agent of the Mercers' Company, into the Low Countries. He must have been a man of some wealth and consideration, for in 1464 he and Richard Wethenhall were appointed by Edward IV. "ambassadors and special deputies" to continue and confirm a treaty of commerce between him and Philip duke of Burgundy; and, upon the marriage of Edward's sister Margaret with Charles duke of Burgundy, he was appointed to the household retinue of the princess, by whom he appears to have been treated with much familiarity and confidence; for at her instigation he first commenced his literary labours, and he mentions her as repeatedly commanding him to amend his English. His first work was a translation of the *Recuyell of the Historyes of Troye*, which he afterwards printed at Strasbourg, when his leisure had allowed him to turn his attention to the study of printing. The first production of his press is allowed to be the French *Recuyell* above mentioned, his second the *Oracion of John Russell on Charles Duke of Burgundy being created a Knight of the Garter*, which took place in 1469. Of his transactions between 1471 and 1474 there is no record; probably he was engaged in the diligent pursuit of the art, and preparing to transfer his materials to England, which he accomplished some time before 1477, when we find him printing in or near the Abbey of Westminster, of which Thomas Milling, bishop of Hereford, was at that time abbot. The first production of his English press was the *Game of Chess*, bearing date 1474, which work, however, some assert to have been printed by him at Cologne. The following is a specimen of this famous book, the initial letter being printed in red:—

Thus ought the Quene be maad / ſhe ought to
be a fair lady ſittynge in a chayer and crowned
wyth a corone on her heed and cladd wyth a
cloth of gold ⁊ a mantyll aboue furrid wyth ermynes

His next production was the *Boke of the hoole lyf of Jason*; but his first book bearing date and place in the colophon is the *Dictes and Sayings of Philosophres*, a translation from the French by the gallant Earl Rivers, "at Westmestre, the yere of our lord m. cccc. lxxvij." From this time he continued both to print and translate with great spirit. His "capital work" was a *Book of the noble Historyes of Kyng Arthur*, in 1485, the most beautiful production of his press.

There is but one copy of any of Caxton's works printed upon vellum; it is the *Doctrinal of Sapyence*. "Translated out of Frensshe in to Englysshe by wyllyam Caxton at Westmestre. Fynyshed the vij day of May the yere of our lord m.cccc.lxxix. Caxton me fieri fecit." This unique copy is in the library at Windsor, and it is in beautiful preservation. It is moreover doubly unique, for it contains an additional chapter, to be found in no other copy whatever, and which is entitled "Of the negligencies happening in the Masse and of the Remedies. Cap. lxiiij." It is a curious treatise of minute omissions and commissions likely to occur in the service of mass, with directions how to remedy such evils. Of their importance here are two specimens, "If by any negligence fyl (fall) any of the blood of the Sacrament on the *corporas*, or upon any of the vestments, then ought to cut off the piece on which it is fallen, and ought well to be washen, and that piece to be kept with the other relics." "And if the body of Jesu Christ, or any piece, fall upon the palé of the altar, or upon any of the vestments that ben blessed, the piece ought not to be cut off on which it is fallen, but it ought right well to be washen, and the washing to be given to the ministers for to drink, or else drink it himself." This singular treatise finishes with this grave confession, "This chapitre to fore I durst not sett in the booke, by cause it is not convenient ne appertaining that every lay man should know it et cetera." At the usual termination of this work is that colophon of Caxton which is given amongst the illustrations of this article in Plate III.; it is, however, considerably reduced.

The Royal Library possesses another work of Caxton, which, as a *perfect* copy, is also unique. This is the "Subtyl Historyes and Fables of Esope. Translated out of Frenshe in to Englyshe by Wyllyam Caxton at Westmynstre In the yere of our lord m cccc lxxxiij Emprynted by the same the xxvj daye of Marche the yere of our lorde m cccc lxxxiiij And the fyrste yere of the regne of kyng Rycharde the thyrde." It consists of 142 leaves. Each fable is illustrated by a rude wood-cut, all of which are said to have been executed abroad, where similar editions of Æsop were frequently printed. They are, however, most probably copied; for there is nothing either in their design or execution that a most moderate artist might not perform; and this will equally apply to other wood-cuts interspersed in Caxton's works.

It has been said that the works of Caxton have been eagerly sought for by English bibliomaniacs. The most remarkable instances of this are the enormous prices given for some of them at the sale of the Duke of Roxburghe's library before mentioned. The *Chastysing of God's Children* was knocked down to Earl Spencer for L.146. The *Sessions Papers* were bought for the Society of Lincoln's Inn for L.378. The Duke of Devonshire gave L.351. 15s. for *The Mirrour of the World*, and L.180 for the *Kalendayr of the Shyppers.* Gower's *Confessio Amantis* produced L.366; *The Boke of Chyvalry*, L.336. The *Recuyell of the Historyes of Troye* gave rise to a startling contest. It was the identical copy presented by Caxton to Elizabeth Grey, queen of Edward IV. and sister of his patroness. "Sir Mark Sykes vigorously pushed on his courser till five hundred guineas were bidden; he then reined in the animal, and turned him gently on one side 'toward the green sward.' More hundreds are offered for the beautiful Elizabeth Grey's own copy. The hammer vibrates at nine hundred guineas. The sword of the marquess is in motion, and he makes another thrust—'One thousand pounds.' 'Let them be guineas,' said Mr Ridgway, and guineas they were. The marquess now recedes. He is determined upon a retreat; another such victory as the one he has just gained (the Valdarfar Boccaccio) must be destruction; and Mr Ridgway bears aloft the beauteous prize in question." (Dibdin.) At Mr Willett's sale *Tullius of Old Age* produced L.210, and became the property of the Duke of Devonshire.

The following are specimens of Caxton's *Pilgrimage of the Sowle*, and of the *Royal Book*:

O Glorious Jheſu. O mekeſt Jheſu. O mooſte
ſwetteſt Jheſu/I praye the/that I may haue trewe con-
feſſion/ contricion/ and ſatiſfaction or I dye/And that I

WHan I remembre and take hede of the conuerſacion of
vs that lyue in this wretched lyf.in which is no ſuerte
ne ſtable abydyng. And alſo the contynuel teſynes of euery

He must have been a man of wonderful perseverance and erudition, cultivated and enlarged by an extensive knowledge of books and the world. Of his industry and devotedness some idea may be formed, when Wynkyn de Worde, his successor, states, in his colophon to the *Vitæ Patrum*, that Caxton finished his translation of that work from French into English *on the last day of his life.* He died in 1491, being about fourscore years of age. His epitaph has been thus written by some friend unknown: "Of your charite pray for the soul of Mayster Willyam Caxton, that in hys tyme was a man of moche ornate and moche renommed wysdome and connynge, and decesed full crystenly the yere of our Lord MCCCCLXXXXI.

> Moder of Merci shyld him from thorribul fynd,
> And bryng hym to lyff eternal that neuer hath ynd."

The type used by Caxton is in design very inferior to that used upon the Continent even earlier than his period; but in the latter part of his life he very materially improved his founts, and some of his later productions are very elegantly cut. The design is peculiar to him, and is said to be in imitation of his own hand-writing; it bears, however, some resemblance to the types of Ulric Zell, from whom Caxton derived most of his instruction, and is something between *Secretary* and *Gothic.* He appears to have had two founts of *English*, three founts of *Great Primer*, one *Double Pica*, and one *Long Primer.*[1] He used very few ornamented initial letters, and those he did employ are very inferior in elegance to those of foreign printers. He preferred inserting a small capital letter within a large space, and leaving the interval to be filled up according to the taste of the illuminator, owing to which many excellent performances are destitute of these beautiful ornaments. Caxton's ink was not remarkable for depth of colour or richness; his paper was excellent; and he probably used presses of the same construction as the continental printers. His works are not very rare, but are highly prized by English collectors. Copies of one or more of his works are to be found in most collections of any pretension, and are well worthy of inspection. The number of his productions is sixty-two. Although Caxton was the first English printer, he was not the only one of his day, Wynkyn de Worde, Lettou and Machlinia, Hunte, Pynson, the Oxford printer whoever he may have been, and he of St Alban's, being his contemporaries.

Wynkyn de Worde.

WYNKYN DE WORDE came, as we have already seen, from Germany with Caxton, and remained with him in the superintendence of his office until the day of his death, when he succeeded to the business. He was a native of Lorraine, and evidently a man of considerable information and taste, and of great spirit in the conduct of his affairs. After his succession to Caxton's business, he carried it on in the same premises for about six years, when he removed to the "Sygn of the Sonne in flete strete, against the condyth." De Worde appears to have immediately commenced a complete renovation of the art, cutting many new founts of all sizes, with vast improvement of the design and proportion; he moreover provided his contemporaries, then becoming very numerous, with type; and it is even said that some of the letter used by English printers less than a century ago are from his matrices, nay, that the punches are still in existence. He was the first (or Pynson) to introduce Roman letters into England, which he made use of amongst his Gothic to distinguish any thing remarkable, in the same manner as Italic is used in the present day. His works amount to the extraordinary number of four hundred and eight. "His books are, in general, distinguished by neatness and elegance, and are always free from professed immorality. The printer has liberally availed himself of such aid as could be procured from the sister art of engraving; although it must be confessed that by far the greater, if not the whole, number of wood engravings at this period are of foreign execution; nor is it without a smile that the typographical antiquary discovers the same cut introduced into works of a directly opposite nature."

In his *Instruction for Pilgrims to the Holy Land*, printed in 1523, the text of which is in Roman, and the marginal notes in Italics, he makes the first use in England of Greek, which is in moveable type, of Arabic and Hebrew, which are cut in wood; and the author complains that he is obliged to omit a third part, because the printer had no Hebrew types. Appended to the work are three Latin epistles, in which he makes use of Arabic.

His works are, of course, not so rare as those of his predecessor, but are nevertheless much sought after; and, when sold by the side of the Caxtons at the Duke of Roxburghe's sale, produced large prices. *Bartholomæus de Proprietatibus Rerum*, the first book printed on paper made in England, was bought by the Duke of Devonshire for L.70. 7s.

---

[1] These are terms by which modern English printers distinguish the sizes of their type.

Chaucer's *Troyius and Cresseide*, L.43; Hawys' *Exemple of Vertu*, L.60; *Passetyme of Pleasure*, L.81; *Castell of Pleasure*, L.61; *The Moste Pyteful Hystorye of the Noble Appolyon, Kynge of Thyre*, L.110.

De Worde died about the year 1534. In his will, still in the Prerogative Office, dated 5th June 1534, he bequeaths many legacies of books to his friends and servants, with minute directions for payment of small creditors and forgiveness of debtors, betokening a conscientious and kindly disposition. His device is generally that of Caxton, with his own name added to the bottom; but he also used a much more complicated one, consisting of fleurs-de-lis, lions passant, portcullis, harts, roses, and other emblazonments of the later Plantagenets and the Tudors. A fac-simile of the former will be found in Plate III.

Lettou.

JOHN LETTOU and WILLIAM MACHLINIA printed separately and jointly before the death of Caxton, but were very inferior to him in every respect; their type being most especially barbarous. Their works are not very numerous, and are principally upon legal subjects; they printed the first edition of Lyttleton's Tenures.

Pynson.

RICHARD PYNSON was a Norman by birth, and studied the art of printing under his "worshipful master William Caxton." It would seem that he was an earlier printer than Wynkyn de Worde, having established an office before the death of Caxton. His first work is of date 1493, and was printed "*at the Temple-bar of London.*" He enjoyed high patronage, and was appointed by Henry VII. to be his printer before 1503. He is perhaps inferior to De Worde as a typographer, his first types being extremely rude. He afterwards used a fount of De Worde's, and another peculiar to himself in this country, probably imported from France. Some of his larger works, Fabian's Chronicle, Lord Berner's translation of Froissart (which are the first editions of these important additions to English literature), and some of his law-works, are very fine specimens of the art. His device was a curious compound of R and P, on a shield which is sometimes supported by two naked figures.

Early English printers.

Of Julian Notary, William Faques, Henry Pepwell, and others, it is unnecessary even to mention their names, inasmuch as they add little that is interesting to the history of English typography.

Grafton.

RICHARD GRAFTON, however, claims especial notice. He was by trade a grocer, although of good family. Of his education nothing appears; but he was one of the most voluminous authors of his time, having, by his own account, written a considerable portion of Hall's Chronicles, an Abridgment of the Chronicles of England, and a Manual of the same, a Chronicle at Large, and other books of historical character, under what circumstances is not known. In 1537 Grafton published Thomas Mathew's translation of the Bible, which was printed abroad, but where is not satisfactorily ascertained; and in 1538 the Testament translated by Miles Coverdale, which was printed at Paris by Francis Regnault. At this time it would not appear that English printers were in high estimation; for Lord Cromwell, desirous of having the Bible in the English language, thought it necessary to procure from Henry VIII. letters to the king of France for license to print it at Paris, and urged Bonner to tender his earnest assistance. Bonner entered upon the undertaking with such zeal, that in recompense he was soon afterwards appointed to the bishopric of Hereford. Miles Coverdale had charge of the correctness (see his letter, Gent.'s Mag. 1791), and Richard Grafton and Edward Whitchurch were the *proprietors;* but under what arrangement does not appear. When the work was on the point of completion, the Inquisitors of the Faith interfered, seized the sheets, and Grafton, Whitchurch, and Coverdale, were compelled to make precipitate flight. The avarice of the lieutenant-criminal induced him to sell the sheets for waste paper instead of destroying them, and they were in part repurchased. The Testament was intrusted to Francis Regnault, whose brother used the tasteful colophon which will be found in Plate III. Under the protection of Cromwell they next, after many difficulties, obtained their types and other materials from Paris, and the Bible was completed at London in 1539. "Thus they became printers themselves, which before this affair they never intended." The edition consisted of 2500 copies. Cromwell next procured for them a privilege (not an exclusive one, however) for printing the Scriptures for five years. Very shortly after the death of Lord Cromwell, Grafton was imprisoned for printing Mathew's Bible and the Great Bible, his former friend Bonner much exaggerating the case against him. The prosecution, however, was not followed up; but in a short time he was, with Whitchurch, appointed printer to Prince Edward, with special patents for printing all church-service books and primers. The document is curious. It recites that such "bookes had been prynted by strangiers in other and strange countreys, partely to the great losse and hynderance of our subjects, who both have the sufficient arte, feate and treade of prynting, and partely to the setting forthe the bysshopp of Rome's usurped auctoritie, and keping the same in contynuall memorye;" and that, therefore, of his "grace especiall, he had granted and geven privilege to our wel-biloved subjects Richard Grafton and Edward Whitchurch, citezeins of London," exclusive liberty to print all such books for seven years, upon pain of forfeiture of all such books printed elsewhere.

One Richard Grafton, supposed to be the above, was member of parliament for the city of London in 1553–54, and also in 1556–57, and in 1562 was member for Coventry. He is supposed to have died about 1572, and not in very affluent circumstances. He used a punning, or, as the heralds would call it, a canting device, of a young tree or *graft* growing out of a *tun*. His works are distinguished for their beauty, and are very numerous and costly. He was one of the most careful and meritorious of English printers.

These are the titles of a few of his early Bibles, &c.

The Byble, 1537, folio. "The Byble, which is all the holy Scripture: In whych are contayned the Olde and Newe Testament truly and purely translated into Englysh by Thomas Mathew. Esaye 1 ☞ Hearcken to ye heauens, and thou earth geaue eare: For the Lorde speaketh. M.D.XXXVII." The title of the New Testament is, "The newe Testament of our sauyor Jesu Christ, newly and dylygently translated into Englyshe, with Annotacions in the Mergent to help the Reader to the vnderstandyng of the Texte." This was printed in France.

The New Testament, Latin and English. 1538. Octavo. "The new testament both in Latin and English after the vulgare texte; which is red in the churche. Translated and corrected by Myles Couerdale: and prynted in Paris, by Fraunces Regnault. M. CCCCC. XXXVIII in Nouembre. Prynted for Richard Grafton and Edward Whitchurch. cytezens of London. Cum gratia & priuilegio regis."

The Byble in Englysshe. 1539. Folio. "The Byble in Englyshe, that is to saye the content of all the holy Scrypture, bothe of ye olde, and newe testament, truly translated after the veryte of the Hebrue and Greke textes, by ye dylygent studye of dyuerse excellent learned men, expert in the forsayde tongues. *Prynted by Rychard Grafton, and Edward Whitchurche. Cum priuilegio—solum.* 1539." This is a very superb book, and is the one which was commenced at Paris and finished at London under the circumstances before related.

NEWE TESTAMENT IN ENGLYSSHE. 1540. Quarto. "Translated after the texte of Master Erasmus of Roterodame."

THE PRYMER. English and Latin. 1540. Octavo.

THE BYBLE IN ENGLYSHE. 1540. Folio. A noble volume, called, from the preface, Cranmer's Byble.

The Byble in Englyshe. 1541. Folio. "The Byble in Englyshe of the largest and greatest volume, auctorised and appoynted by the commaundement of oure moost redoubted prynce and soueraygne Lorde, Kynge Henrye the VIII, supreme head of this his churche and realme of Englande: to be frequented and vsed in euery Churche within this his sayd realme, accordyng to the tenoure of hys former Jniunctions geuen in that behalfe. Ouersene and perused at the cōmaundemēt of the kynges hyghnes, by the ryght reuerend fathers in God Cuthbert byshop of Duresme, and Nicholas, bisshop of Rochester." The lines of the title are printed alternately red and black.

Such, with many other manuals, primers, &c. were the productions of this most eminent British typographer.

John Day.

John Day was a printer of much eminence; and his works are numerous, beautiful, and useful.

Isaac Jaggard, Edward Blount, &c.

The first complete edition of Shakspeare's Plays was printed by Isaac Jaggard and Edward Blount, in folio, in 1623. Of his single plays, the earliest is "The first part of the Contention betwixt the two famous Houses of Yorke and Lancaster," which was printed by "Thomas Creed for Thomas Millington, and are to be sold at his shop, under Saint Peter's Church, Cornwall" (Cornhill), in 1594. These plays were printed by various typographers, amongst whom appear the names of George Eld, Valentine Simmes, R. Young, John Robson, and others who only give their initials.

Peter Parker.

The first edition of Milton's Paradise Lost was printed in quarto by Peter Parker in the year 1667; the Paradise Regained in 1671.

During the troublesome times that preceded the great rebellion, the Puritans, jealously watched and persecuted, introduced the anomaly of ambulatory presses, which were constantly removed from town to town to escape the vigilance of the Star-Chamber. At these presses many of Milton's controversial pamphlets were printed; and it is even said that the identical press at which the *Areopagitica* was printed is still in existence, and was lately in the possession of Mr Valpy, the well-known printer of the Variorum Classics.

It is a very pleasing reflection, that the earlier practitioners of the art did, by their uniform good character and religious turn, tend much to render their profession productive of a highly moral class of literature, and to raise it in the estimation of all men. Had they been less respectable, had they turned their attention to the many ribald and tasteless writings of those times, the effect of the new art would have been to degrade literature and lower morals, to delay the spread of knowledge, and to give a depression to the character of the art and its practitioners, from which possibly they might never have recovered. These excellent and learned men appear to have received their temporal reward, in public estimation, sufficient wealth, and a length of years beyond the ordinary term of mortality.

Oxford.

Setting aside the claim of Corsellis, printing was first practised at Oxford by Theoderic Rood and Thomas Hunte from 1480 to 1485. In Rymer, vol. xv. is a grant by Queen Elizabeth to Thomas Cooper, clerk of Oxford, for the exclusive printing of his Latin Dictionary. In 1585 a printing press was established at the expense of the Earl of Leicester, chancellor of the university. Joseph Barnes was appointed printer to the university in 1585.

Cambridge.

At Cambridge John Siberch printed in 1521, when Erasmus resided there, and probably executed some of his books. Thomas Thomas, M. A. was the first printer to the university in 1584.

St Alban's.

At St Alban's printing was very early practised, certainly in the year 1480. It would appear that the printer was a schoolmaster. It has been asserted, but without shadow of argument, that printing was introduced here many years before Caxton.

Early Scottish printers.

Printing was not introduced into Scotland till thirty years after Caxton had set up his press at Westminster. Under the patronage of James IV., who was a zealous encourager of learning and the useful arts, Walter Chepman and Andro Myllar established the first printing press at Edinburgh, as appears by a royal privilege granted to them in 1507.[1]

The only publications known to have issued from the press of Myllar and Chepman are a collection of pamphlets, chiefly metrical romances and ballads, in 1508, of which an imperfect copy is preserved in the Advocates' Library;[2] and the Scottish Service Book, including the Legends of the Scottish Saints, commonly called the Breviary of Aberdeen, in 1509.[3]

It is difficult to account for the discontinuance of printing in Scotland for about twenty years after this time: probably the disastrous events at the close of the reign of James IV. may have contributed to render it an unprofitable trade; but in its revival by Davidson there was no deterioration, either in the magnitude and importance of the works attempted, or in the mode in which the mechanical part was executed. It was probably about the year 1536 that he printed, in a black-letter folio, "The History and Croniklis of Scotland, compilit and newly correckit be the Reuerend and Noble Clerke Maister Hector Boece. Translatit laitly be Maister Johne Bellenden. Imprentit in Edinburgh be Thomas Davidson, dwelling fornent the Frere Wynd;" and in 1540 he printed the whole works of Sir David Lindsay.

Davidson was succeeded by Lekprevik, Vautrollier, and others; but none were distinguished as printers till the time of Ruddiman.

A mere catalogue of printers would afford little amusement, and less instruction; especially since the productions of the English press, save in the works of the printers above named, not only exhibited no advance, but even much deterioration, in most requisites of good printing. Indeed, to so low a point had the art fallen, and so little spirit was exhibited by English typographers, that the regeneration was left to an alien, whose perception of the inferiority and capacity of improvement at once raised the art to the level of the finest productions of Bodoni and Barbou.

Baskerville, Bulmer &c.

This was John Baskerville, a japanner of Birmingham, who, having realized a considerable fortune, turned his attention to cutting punches for type, and succeeded in producing a series of founts of remarkable beauty, so excellently proportioned, and standing so well, that the best of modern type-founders (and this seems the Augustan age of type-founding) have done no more than vary the proportions and refine the more delicate lines and strokes. Added to this, his press-work is of most excellent quality; his paper the choicest that could be procured; and his ink has a richness of tone, the mode of producing which has died with him. The works of Baskerville are amongst the choicest that can adorn a library. He died in 1775. His types and punches were purchased to print the splendid edition of Voltaire's works at Paris. He was worthily succeeded by BULMER, whose magnificent Shakspeare and Milton are amongst the most superb books ever issued from the press, and, with Macklin's Bible and Ritchie's, Bensly's Hume, and other works, may be fearlessly produced to win for this country the palm of fine printing; whilst in Scotland, THOMAS RUDDIMAN and the two FOULIS may challenge the prize of classical typography from Aldus and the Stephani. Indeed, the larger Greek types of the Foulis are without parallel for grandeur, their press-work is beautiful, and their correctness beyond all praise.

---

[1] "James, &c. To al and sindrj our officiaris liegis and subdittis quham it efferis, quhais knawlage thir our lettres salcum, greting; Wit ye that forsamekill as our lovittis servitouris Walter Chepman and Andro Millar, burgessis of our burgh of Edinburgh, has at our instance and request, for our plesour, the honour and proffit of our Realme and liegis, takin on thame to furnis and bring hame ane prent, with all stuff belangand tharto, and expert men to use the samyne, for imprenting within our Realme of the bukis of our Lawis, actis of parliament, crouiclis, mess bukis, and portuus efter the use of our Realme, with addicions and legendis of Scottis sanctis, now gaderit to be ekit tharto, and al utheris bukis that salbe sene necessar, and to sel the sammyn for competent pricis, be our avis and discrecioun thair labouris and expens being considerit," &c.

"Geven under our prive Sel at Edinburgh the xv day of September, and of our Regne the xx^ti^ yer."

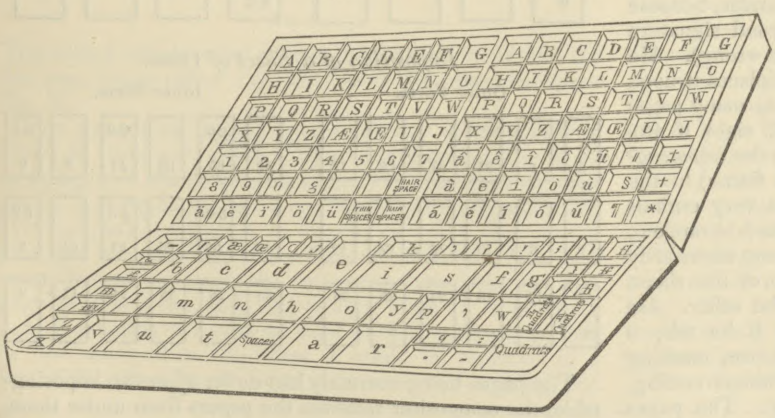
[2] These pamphlets were reprinted in a handsome quarto volume, edited by Mr David Laing. The preface contains much accurate information regarding early printing in Scotland.

[3] Of this Service Book, which forms two volumes octavo, handsomely printed with red and black letter, in the years 1509 and 1510, a beautiful copy is preserved in the University Library of Edinburgh. As the name and device of Walter Chepman occur in the work, without any mention being made of his partner, we are led to the conclusion that Andro Myllar, if then alive, had relinquished his share in the concern.

Modern printers, with all their faults, are not degenerate successors of these worthies. The works from present offices that make pretensions to fine printing need not be ashamed of comparison with these *chefs-d'œuvres;* whilst, from the vast improvements in the mechanism of the art in all its branches, paper, presses, ink, type, and other adjuncts, the average of the printing of the present day is infinitely superior to that of the last century. But in what relates to practical skill, correctness, taste, and diligence, we cannot hope to excel, though we may perhaps equal, these departed masters.

PRACTICAL PRINTING.

The first operation when the new fount[1] has entered the doors of the printing-office, is to *lay* it in the *cases* (fig. 1). These are always in pairs; the *upper case* being divided into equal spaces or *boxes;* the part on the left of the broader division being appropriated to CAPITAL letters, figures, diæresis vowels, particular *sorts*, &c.; that on the right to SMALL CAPITALS, accented letters, and references. The letters and figures are arranged in alphabetical and numerical order, from left to right. The *lower case* is divided into unequal portions, according to the average occurrence of the particular letters; for the compositor (the workman whose duty it is to lay the fount, and afterwards to place together or *compose* the separate types into words) never looks at the face of the letter he picks up, but unhesitatingly plunges his fingers into any box, being sure that the letter he picks out thence is the one to which that box is appropriated, and consequently the one he requires. As there is no external mark or guide attached to the different boxes to denote the letters they contain, a stranger is not a little surprised and puzzled at the eccentric movements of the workman's hand. Accordingly, it will be observed, upon looking at fig. 1, that the letter e has a box one-half larger than c, d, m, n, h, u, t, i, s, o, a, r; and these are twice the size of b, l, v, k, f, g, y, p, w, or the comma; and four times the size of z, x, j, q, or the [] crotchets, full points, &c. These boxes are not arranged in alphabetical order, but those of most frequent occurrence are placed about the middle of the case to diminish the distance the hands of the compositor have to travel in picking up and receiving the types. There are also other pairs of cases similarly arranged for the *italic* letters. The following are the proportions of some of the letters in a fount of pica of 800 lb. weight:—



A B C D E F G A B C D E F G
H I K L M N O H I K L M N O
P Q R S T V W P Q R S T V W
X Y Z Æ Œ U J X Y Z Æ Œ U J
1 2 3 4 5 6 7 â ê î ô û ‖ ‡
8 9 0 £ HAIR SPACE à è ì ò ù § †
ä ë ï ö ü THIN SPACES HAIR SPACES á é í ó ú ¶ *
- æ œ k ! ; ff
b c d e i s f g fi
l m n h o y p , w
x v u t Spaces a r q : . - Quadrats

Fig. 1.

Capitals, from 400 to 600 of each, but of J 80, Q and X 180, and Z 180.

Small capitals, from 150 to 300 of each, excepting J, Q, X, and Z, which, as in the capitals, are reduced in number.

a	8,500	b	1,600	j	400	z	200
e	12,000	c	3,000	k	800	&	200
i	8,000	d	4,000	m	3,000	,	4,500
o	8,000	f	2,500	n	8,000	.	2,000
u	3,400	h	6,400	q	500		

In a whole fount there are about 150,000 letters, spaces, and figures.

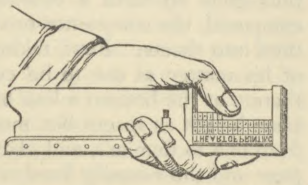


Fig. 2.

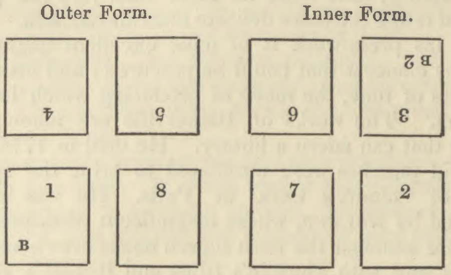
The compositor, having placed his copy upon a part of the upper case little used, and having received the necessary directions, takes up an instrument called a *composing-stick* (fig. 2), (which, as well as the way of holding it and its use, will be better understood by reference to the drawing than by description), and sliding the inner moveable portion wider or closer according to the desired width of the page, he fastens it with a screw; he then cuts a piece of brass rule to fit in easily between the end of the stick and slide, and which is called the *setting-rule.* This rule causes the letters to slip down without any obstruction from the screw-holes of the stick, or the nicks which serve to distinguish one fount from another and enable the compositor, by turning them outwards, to place the letters in their proper position. He then reads the first few words of his copy, takes first a capital letter from the upper case, the succeeding letters from the lower case, and at the conclusion of the word a *space*, which is merely the shank of a letter without any face, and not so high as a letter by about one-fourth part; and therefore, not receiving the ink, forms the blank space between words; but sometimes, through carelessness, it is allowed to stand up, in which case it is a fearful blotch upon a fair page, and must have been observed by most readers. He then proceeds with his next word, which will probably consist of lower-case letters only; and so on until he has arrived at the end of his line. It is most likely, however, that the words he has occasion to compose, with the necessary spaces, will not fill up the exact width of the line, and that there will be sometimes too much, sometimes too little room, for getting in the whole or part of the next word. In this case he has to consider whether it will be better to crowd the line and get in the word or syllable, or make the line more open and take it over to the next line; his care being that his matter, when composed, shall not look too open or too close. Having decided, he takes out the spaces he has inserted, and puts in their stead others of greater or less width, as the case may require, in such a manner that on the face of the line being touched, it shall not feel loose, or require any particular pressure to force down the last letter into its proper place. This being accomplished in an artist-like manner, he takes out his setting-rule and places it in front of his line, and with a gentle pressure of his thumb forces both back into the composing-stick; he then proceeds in a similar manner with other lines until his stick is full, when, placing it upon the *frame* on which the cases rest, his setting-rule being in front, he lifts his lines out of the stick and places them upon a proper instrument called a *galley*. If, however, the matter is to be *leaded*, that is, if the lines of types are to be more apart than usual, the process is a little different. The compositor then has before him a quantity of pieces of metal called *leads*, of the exact width of the page, only one-fourth, one-sixth, or one-eighth of the body of the type, and not higher than spaces. After composing a line, before moving his setting-rule, he takes one or more of these and places it before the line; he then takes out the setting-rule, and proceeds as above described. Having thus gone on until a considerable quantity of matter is composed, the compositor next makes it up into pages, and then into sheets. First, taking by portions as many lines of his matter as are to be contained in a page, he adds thereto at the bottom a line of quadrats, which are of the same height as spaces but much larger, varying in length from one to four m's, and places at the top the folio of the page and the *running head* or line which indicates the title of the work or the subject of the page or chapter, and then adds such leads or other things as may be necessary; taking care that in the first page he places the *signature* (a letter of the alphabet intended for a guide to the binder, because by keeping this always outside, and the second signature on the next leaf, he cannot fold the sheet wrong). He next ties it tightly round with page-cord, and places it upon a piece of coarse paper. Having made up as many pages as the sheet consists of, viz., four if folio, eight if 4to, sixteen if 8vo, he next lays them down upon the *imposing-table*[1] (a large plate of iron screwed on to a frame) in the necessary order. This is, to a stranger, a very curious arrangement; they appear to him to be placed at random, without any design or fixed rule, and as they are necessarily laid down in two divisions, one for each side of the sheet, one is of consequence the very reverse of the other. He may easily instruct himself, however: for if he take a sheet of paper and fold it into any required size, marking the folios with a pencil, and then open it without cutting, he will find they fall in curious irregularity. The pages are laid down on the table reverse of the order they have on the paper; for it must be remembered that every type and every page is like a seal, the reverse of the impression it leaves; consequently, were the pages laid down as on the marked paper, viz., the first page on the right hand, it would, in type, be at the extreme left, and so on. The following schemes of the *laying down* or *imposition* of a sheet of 4to, 8vo, 12mo, and 18mo, will give some idea of the apparent confusion of this process:—

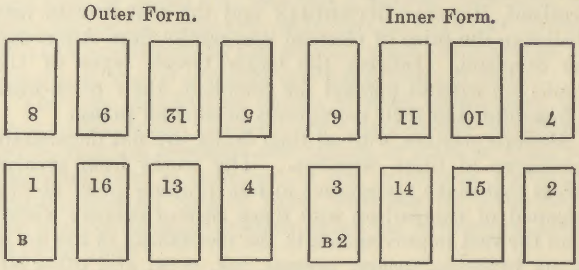
---

[1] A fount is any weight of type of the same body and face, consisting of every letter, stop, figure, &c., in certain proportions, as stated above, together with spaces and quadrats. (See TYPE-FOUNDING.)

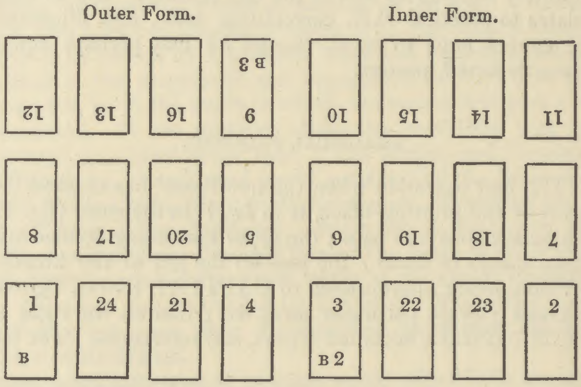
Imposition of a Sheet of 4to.



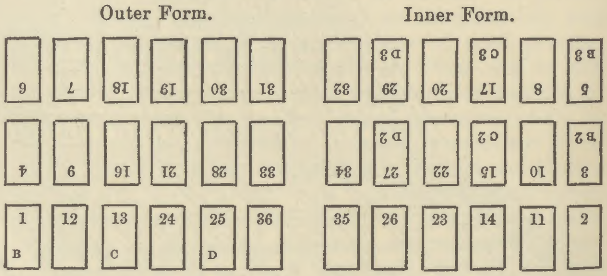
Imposition of a Sheet of 8vo.



Imposition of a Sheet of 12mo.



Imposition of a Sheet of 18mo.



The pages being correctly laid down upon the imposing-table, the compositor removes the papers from under them, and next takes in both hands a *chase* (a frame of iron divided by cross-bars into four compartments, the inner angles of which are made rectangular with much care) and places it over them; and then having ascertained the size of the paper to be used, adjusts pieces of wood or metal, called *furniture*, between them. Within the chase, but next to the pages, he places other pieces of wood or iron called *side* and *foot sticks*, which are rather wider at one end than the other, and between these and the chase small pieces of wood, which decrease in width in the same proportion as the side-stick, and which are called *quoins.* He now takes off the cords from the pages, and, as he removes each cord, he tightens the adjacent quoins that the letters at the sides of the pages may not slip down. When all the pages are untied, and the quoins pushed up with his finger and thumb, he planes down the pages gently with a *planer* (a piece of beech perfectly plane and smooth on the face, about 9 inches long, 4½ inches wide, and 2 inches thick), to prevent any of the letters from standing up. With a *shooting-stick* (which formidably-named weapon is merely a piece of hard wood,[1] a foot in length, an inch and a half in width, and half an inch in thickness) and a mallet he forces the quoins towards the thicker ends of the side and foot sticks, which consequently act as gradual and most powerful wedges, forcing the separate pieces of type to become a compact and almost united body, so that, the pages being securely *locked up* and again planed down, the whole mass, consisting of many thousand letters, may be lifted entire from the table.

---

[1] Formerly a large slab of marble or stone was used for this purpose; but as it was liable to split, and to have its smooth surface indented, a plate of iron turned in a lathe is now very generally substituted.

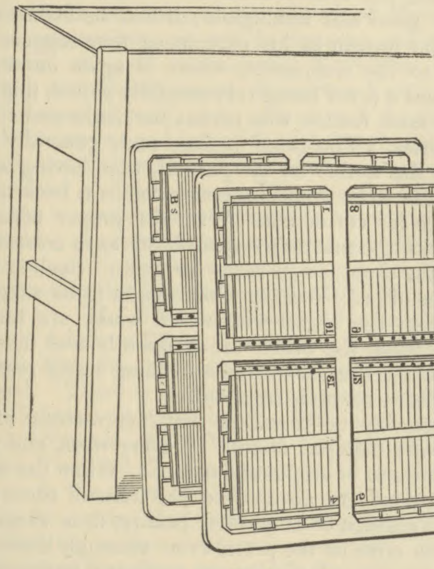


Fig. 3.

This united mass is called a *form;* that one which contains the first page being called the *outer form,* the other the *inner* (fig. 3).

The compositor is paid by the number of thousands of letters he composes, which is thus ascertained:—The letter m, being on a shank which is supposed to have its four sides parallel and equal, is taken as the standard; he ascertains how many m's the page is in length, including the running head and the white line at the bottom; that is, in fact, how many lines of the particular type used there would be in a page of the given size, supposing it were all solid type; next, how many m's (laid on their side) it is in width, that is, how many times the letter m would be repeated in a line of the given length were it to consist of nothing but m's so laid. This latter sum is then doubled, because experience shows that the average width of the letters is one-half of the depth, or one-half of that of the letter m. The length of the page is then multiplied by the product of this doubled width, then by the number of pages in the sheet, and the result will give the average number of letters in the sheet. This will be much better understood by the following *casting-up* of a sheet of 8vo in pica:—

Number of m's long........................	47
... m's wide 24, × 2..............	48
	376
	188
	2256
Number of pages in a sheet of 8vo......	16
	13536
	2256
	36096

The compositor therefore is paid for composing 36,000 letters; for the odd figures are dropped, unless they amount to or exceed 500, when they are paid for as if they completed another 1000. If the sheet be of solid type, of the ordinary size, the price paid in London is sixpence per 1000 letters; if in the small type called minion, sixpence farthing; in nonpareil, sevenpence; in pearl, eightpence. If the work be composed from print copy, the price is three farthings per 1000 less than it would be paid if the copy were manuscript. If, however, the type be leaded, the price is a farthing per 1000 less for founts above pearl. If the work is to be stereotyped, and high spaces are used, it is subject to an additional charge of a farthing per 1000; if low spaces, of a halfpenny per 1000. Works in foreign languages, in type of the ordinary size and character, are paid one halfpenny per 1000 more, and three farthings per 1000 more in the smaller. Greek, with leads and without accents, is eightpence halfpenny per 1000; without leads or accents, eightpence three farthings; with accents, tenpence farthing. Hebrew, Arabic, Syriac, &c., are paid double.[2] The compositor, it appears, must therefore pick up 72,000 letters before he can receive an ordinary week's wages, must make up his matter into pages and impose them, and, moreover, correct all the blunders mischance or carelessness may have occasioned, with great expenditure of time also in many other particulars; but, as is hereafter described, he must have previously placed every one of these 72,000 into the appropriate boxes whence he has withdrawn them in composition. Now it is usually reckoned that this latter operation, called *distributing,* occupies one-fourth of a compositor's time, and the other operations another fourth; he has therefore only one-half of his time for composition; consequently he must pick up letters at the rate of 144,000 per week, 24,000 per day, or 2000 per hour. His rapidity of motion is therefore wonderful, and the exertion is so long continued, that the business, although apparently a light one, is in fact extremely laborious.

The number of thousands of letters in a sheet necessarily varies with the size of the type, width and length of the page, and the number of the pages. The example above given is the casting-up of an octavo sheet of pica solid, the page being of moderate size; a similar sheet of brevier would contain 81,000 letters, and the cost of composing it would be L.2, 0s. 6d. Single tables, forming one uninterrupted mass of type, will sometimes contain 250,000 letters; and the labour of the compositor being very great in getting them up, he is paid double. Consequently the cost of composing such a table in pearl or diamond (as the 13th of Bell's *Chronological Tables*, 4th edit.) would be not less than L.16, 13s. 6d., without extra charges. Yet this large number of types, by the power of the wedge-formed side and foot sticks and quoins, is compressed into so solid a mass that it can be moved without much danger of disruption.

---

[1] Iron or gun-metal is now generally substituted, as being more durable.

[2] In 1804, after a protracted litigation before the Court of Session, the journeymen compositors of Edinburgh succeeded in obtaining the sanction of the Court for an advance of one penny per thousand letters, or, upon an average, about one-fourth on the prices of their work. The grounds upon which the Court rested this decision were, that the wages were much too low; that they had remained for forty years unaltered, whilst the price of the necessaries of life had very much increased; that although it was proper to avoid a rise of wages which might lead to idleness, yet it was equally necessary to place the workmen upon a respectable footing, so as to enable them to do their work properly, and also to encourage them in cultivating and acquiring that degree of literature by which the public must infallibly be benefited; and that the fair criterion was, to make the wages of Edinburgh bear the same proportion to those of London which they did in the year 1785, before the London prices were raised. That a court of law, whose province it is not to legislate, but to apply and enforce existing statutes, should have entertained a question regarding the price of labour, for the regulation of which there not only existed no law, but which had never been deemed a fit subject for legislative interference, appears to be a very singular incident in the history of judicial procedure. The prices thus fixed, however (namely, 4½d. per 1000 for book-work, with an additional halfpenny if nonpareil, and a penny if pearl, and 5½d. for law-papers and jobs), being regarded as not unreasonable, have ever since been adhered to by every respectable establishment in Edinburgh.

The sheet being now imposed, an impression is taken, called a *proof*, which is carried down to the reader, who, having folded the proof in the necessary manner, first looks over the signatures, next ascertains whether the sheet commences with the right signature and folio, and then sees that the folios follow in order. He now looks over the running heads, inspects the proof to see that it has been imposed in the proper furniture, that the chapters are numbered rightly, and that the directions given have been correctly attended to, marking whatever he finds wrong. Having carefully done this, he places the proof before him, with the copy at his left hand, and proceeds to read the proof over with the greatest care, referring occasionally to the copy when necessary, correcting the capitals or italics, or any other peculiarities, noting continually whether every portion of the composition has been executed in a workman-like manner; and having fully satisfied himself upon these and all technical points, he calls his reading-boy, who, taking the copy, reads in a clear voice, but with great rapidity and often without the least attention to sound, sense, pauses, or cadences, the precise words of the most crabbed or intricate copy, inserting, without pause or embarrassment, every interlineation, note, or side-note. The gabble of these boys in the reading-room, where there are three or four reading, is most amusing, a stranger hearing the utmost confusion of tongues, unconnected sentences, and most monotonous tones. The readers plodding at their several tasks with the most iron composure, are not in the least disturbed by the Babel around them, but follow carefully every word, marking every error, or pausing to assist in deciphering every unknown or foreign word. This first reading is strictly confined to making the proof an exact copy of the manuscript, and ascertaining the accuracy of the composition; consequently first readers are generally intelligent and well-educated compositors, whose practical knowledge enables them to detect the most trivial technical errors. Having thus a second time perused the proof, and carefully marked upon the copy the commencement, signature, and folio of the succeeding sheet, he sends it by his reading-boy to the composing-room to be corrected by the workmen who have taken share in the composition. These immediately divide the proof amongst them, and each, taking that portion of it which contains the matter he had composed, and going to his cases, gathers the letters marked as corrections in the margin, together with a quantity of spaces of all sizes, and returns to the forms, which in the meanwhile one of them has *laid up* on the imposing-table and unlocked. He then with a bodkin lifts up each line in which a correction is required, draws out the wrong letter and inserts the right one, adjusting the spaces in such a way as to compensate for the increased or diminished size of the letter substituted, overrunning carefully several lines should any word have been added or struck out, so that the spacing may be uniform, and the corrected matter exhibit no indication of any alteration having been made. This is an operation requiring much practice and skill; and here is shown the value of attention in the preliminary operations. Should the types have been carelessly laid or inaccurately distributed, should the workman have been negligent in composition, capitalling, or spacing, he will consume as much time in amending his errors as in composing his matter, to the great detriment of his work, the injury and inconvenience of his employer and his companions, and great delay in every department of the printing-office. When every compositor has corrected his matter, that one whose matter is last in the sheet locks it up, and another proof is pulled, which, with the original proof, is taken to the same first reader, who compares the one with the other, and ascertains that his marks have been carefully attended to, in default of which, he again sends it up to be corrected; but should he find his revision satisfactory, he sends the second proof with the copy to the second reader, by whom it undergoes the same careful inspection; but this time, most technical inaccuracies having been rectified, the reader observes whether the author's language be good and intelligible; if not, he makes such queries on the margin as his experience may suggest; he sends it up to the compositor, where it again undergoes correction, and a proof being very carefully pulled, it is sent down to the same reader, who revises his marks and transfers the queries. The proof is then sent, generally with the copy, to the author for his perusal, who, having made such alterations as he thinks necessary, sends it back to the printing-office for correction. With the proper attention to these marks, the printer's responsibility as to correctness ceases, and the sheet is now ready for press. Such at least is the process of proof-reading which ought to be adopted; but now, from the speed with which works are hurried through the press, the proofs are frequently sent out with only one reading, the careful press-reading being reserved until the author's revise is returned.

It need scarcely be remarked that "correctness of the press" is a very material feature in every work, and more especially in those of a scientific nature. When the attention and the mind are devoted to the train of some close argument or passage of surpassing beauty, it is surprising how easily an error of the press, even although it may not injure the sense, and may be as evident "as the sun at noon," will destroy the charm, and break the "thread of the discourse;" and even in works of ordinary reading they are exceedingly offensive. Many curious anecdotes are related of the methods which the earlier printers adopted to attain correctness. It was the glory of the early literati to take charge of the accuracy of new works; and, in return, the value and sale of each edition varied with the skill and reputation of the corrector. Of these, Erasmus is an illustrious example. Many of the first printers were led to the practice of the art by their love of learning, and their anxiety to promote it by the production of classic authors. Hence several are better known in the world of learning than in the circle of bibliographers; as the editors and correctors of valuable works, than as the careful or beautiful printers of them. Aldus, it is true, has so admirably succeeded in both characters that he has fully established his double fame; but whether he most valued himself upon his learning or his skill may be doubted. It would appear from his letters that he considered it as his chiefest duty to correct every sheet that passed through his press. In all his bustle in preparing every material in use in his art, in all his occupations public and private, this important duty was never neglected. He tells us "that he has hardly time to inspect, much less to correct, the sheets which are executed in his office; that his days and his nights are devoted to the preparation of fit materials; and that he can scarcely take food or strengthen his stomach, owing to the multiplicity and pressure of business; meanwhile," adds he, "with both hands occupied, and surrounded by pressmen who are clamorous for work, there is scarcely time even to blow one's nose:" nor did his son or grandson depart from his ways, but did themselves insure the correctness of their works, even when the latter had risen to wealth and eminence, and enjoyed the laborious dignity of a professor's chair. The beautiful Greek works of the Stephani are especially valued for their correctness. Stephens corrected his own press with intense labour and minuteness, and is reported to have adopted a singular plan for obtaining perfect similarity to the copy, by employing females who had not the slightest knowledge of the Greek characters or language to compare every letter of the proof with the manuscript; a labour so intense as to be almost incredible. He is moreover said to have hung up proofs on the doors of his printing-office, and to have amply rewarded any who could detect inaccuracies therein. Coverdale, it will be recollected, corrected the first English Bible and Testament, and received a bishopric as his reward. Foulis, the celebrated printer at Glasgow, adopted the same plan to insure the accuracy of his edition of Horace, which is styled immaculate; in which, however, one error escaped detection, the ode commencing SCRIBERIS Vario, being printed, as originally issued, SCRIBFRIS Vario.

The experience of every printer will furnish a host of laughable errors; and indeed these defects have been deemed of such importance as to deserve preservation. (D'Israeli's *Curiosities of Literature.*) The omission of the word *not* from the seventh commandment, in an edition of the Bible printed by the Stationers' Company, is well known; and the company richly deserved the severe fine they incurred for spreading the immoral command, "Thou shalt commit adultery." The Bible so misprinted has received the name of the "Adultery Bible;" and a copy is preserved in the British Museum, the edition having been carefully suppressed. There is another Bible known as the "Vinegar Bible," from a misprint in the 20th chapter of St Luke, where "Parable of the Vinegar" is printed for "Parable of the Vineyard:" this proceeded from the Clarendon press. In the reign of Charles I. a very curious traffic in Bibles, &c., arose; they were printed by any one who chose, and imported in vast numbers from abroad. It will readily be imagined that these were made for *sale*, not for *use*, and that they abounded with egregious errors; but, what is worse than this, they were full of mistranslations and interpolations, and the omissions were fearful. All these were done as much by design as by accident, the Romanists and sectaries taking the opportunity of advancing their own tenets by interpolating and altering texts to suit their views. These monstrous anomalies produced, however, some good; they occasioned the necessity of the authorized version now in use, and printed under such authority as insures perfect fidelity, whilst there is sufficient competition to make it impossible that the Word of God can ever become a sealed book to the humblest and poorest Christian. Some of the blunders in these editions are sufficiently absurd to overcome the repugnance which must naturally be felt at such license. Thus, in Luke xxi. 28, *condemnation* has been misprinted for *redemption.* In Field's Bible of 1653, called the Pearl Bible, Rom. vi. 13, we find "Neither yield ye your members as instruments of *righteousness* unto sin," for *unrighteousness;* and 1 Cor. vi. 9, "Know ye not that the unrighteous *shall inherit* the kingdom of God?" for *shall not inherit.* It is said that these corruptions are in great measure owing to Field's cupidity, and that he received a bribe of L.1500 from the Independents to alter the text in Acts vi. 3, to sanction the right of the people to appoint their own pastors, "Wherefore, brethren, look ye out among you seven men of honest report, full of the Holy Ghost and wisdom, whom *ye* may appoint over this business," instead of *we.* This Bible is notorious, and, strange to say, valued, for its gross incorrectness. It is asserted that no less than six thousand errors of greater or less magnitude have been noted in it. But the most extraordinary example of carelessness is presented by the Vulgate, the printing of which was sedulously superintended by no less an authority than Sextus V., a curious example of the infallibility of the Pope. To the astonishment of the world, it swarmed with errors; and a whimsical attempt was made to remedy the defects by pasting printed slips of paper over the erroneous passages. As this, however, was exceedingly laughable, the papal authority was exerted to the utmost to call in the edition, and with such effect that it soon became very scarce, and a copy of it has produced the sum of sixty guineas. To add to the absurdity, the volume contains a bull from the Pope anathematizing and excommunicating all printers who, in printing it, should make any alteration in the text. The monkish editor of *The Anatomy of the Mass,* printed in 1561, a work consisting of 172 pages of text and fifteen pages of errata, very amusingly accounts for these mistakes by attributing them to the artifice of Satan, who caused the printers to commit such numerous blunders; but he does not inform us whether it was really the archangel fallen, or only his minor satellite, the printer's devil. The editor of an Ethiopic version of St Paul's Epistles innocently confesses, in palliation of his errors, "that they who printed the work could not read, and we could not print: they helped us and we helped them, as the blind helps the blind."

The sheet being printed off in the way hereafter to be described, and the forms returned by the pressmen to the composing-room, and very carefully washed with lye, and rinsed with water, the compositor lays them up on a letter-board in the sink, and there unlocks them; he then passes one hand backwards and forwards over the pages so as effectually to loosen the type, and at the same time with the other pours on water, till, the lye and ink being washed away, it runs off clear. The forms are then allowed to drain, and carried to the bulks at the ends of the frames. Each compositor employed on the work then takes a share of the letter, and, wetting the face of it plentifully with a sponge, which causes the types to adhere sufficiently to prevent accidents, yet not so much as to retard the workman, takes up a portion on his setting-rule, with the nick upwards, and the face turned towards him; he then takes between his fingers and thumb a few letters, gives a rapid glance at the face to see what letters they are, and then, passing his hand rapidly over the cases, drops each into its appropriate box. In this operation the greatest attention is necessary, for it must be remembered that every letter dropped into a wrong box in distributing is sure to cause an error in composing; for the workman, as before stated, never looks at the letter he takes up, relying upon the correctness of the distribution. Compositors, therefore, should be especially careful, when learning their business, not to sacrifice accuracy to swiftness; for in this instance most especially is it found that too much haste is little speed. If the rapidity of motion in composition strikes the stranger with wonder, what must that of distribution occasion? Most compositors distribute four times as rapidly as they compose; if, therefore, he pick up two thousand letters in an hour, he would distribute eight or ten thousand, or about three per second. His letter being properly distributed, he again proceeds to compose in the manner before described, until the work is finished. The number of times the types are returned to the cases must depend upon the size of the fount. A thousand pounds weight of types would get up five or six sheets; and therefore, in an ordinary octavo volume, the types would be returned five or six times.

Many attempts have been made to substitute machinery for the manual labour of the compositors. The machines of Messrs Young and Delcambre (1842), and of Major

Rosenborg, deserve mention for their great ingenuity; and Major Beniowski has attempted a process by which, by the use of a new description of type, logotypes, cases, and machinery, a great saving of time and money may be effected. But there are requirements in the process of composing which are independent of mechanism, and which have hitherto rendered these inventions practically useless.

THE PRINTING-PRESS.

The press is the machine whereby impressions are obtained of the type, when set up by the compositor as above described. On the skill and care of the pressmen depends the beauty of the work. If the press-work be not good, all the labour of the compositor is thrown away; his work makes no respectable appearance, and the master gets no credit.

It has already been mentioned that very little alteration had been made in the printing-press from the time of the first printers to that of Blaew of Amsterdam, about 1620. Blaew's improvements, although very great, only consisted in alterations in the details, and not in the principle. These presses have in their turn been superseded by those of Lord Stanhope; and the latter has found successful competitors in the Columbian, Albion, and others of more modern invention. Very few of Blaew's construction are now in existence, in England at least, save in old offices, where they are used as proof-presses, or kept merely as curiosities. As a description of these bygone pieces of mechanism would be of little utility, the Stanhope press, by which they have been superseded, has been selected for illustration, for which it is best adapted, from the simplicity of its construction and its being easily explained. The novelty of his lordship's invention consists in an improved application of the power to the spindle and screw, whereby it is greatly increased. Upon reference to fig. 4, it will be seen that this press possesses great strength and compactness. The heavy mass of iron AA, somewhat resembling a vase in outline, is called the *staple*. It is united at the top and bottom, but the neck and body are open. The upper part is called the *nut* B, and answers the purpose of the head in the old press; it is in fact a box with a female screw, in which the screw of the spindle C works; the lower portion of the open part, described as the *neck*, is occupied with a piston and cup D, D, in and on which the toe of the spindle works.

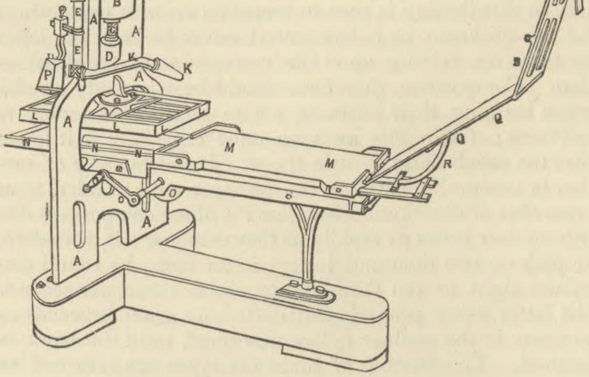

Fig. 4.

On the nearer side of the staple is a vertical pillar or *arbor* A (fig. 5), the lower end of which is inserted into the staple at the top of the shoulder; the upper end passes through a top-plate B, which being screwed on to the upper part of the staple, holds it firmly. The extreme upper end of the arbor (which is hexagonal) receives a head C, which is in fact a lever of some inches in length; this head is connected by a *coupling-bar* E to a similar lever or head D, into which the upper end of the spindle is inserted.

The bar or lever F, by which the power is applied by the workman, is inserted into the arbor, and not into the spindle, by which ingenious contrivance,—1*st*, the lever is in length the whole width of the press, instead of half, as in Blaew's press, and is, moreover, in a much better situation for the application of the pressman's strength; 2*d*, there is the additional lever of the arbor-head; 3*d*, the additional lever of the spindle-head; and, *lastly*, the screw itself may be so enlarged in diameter as greatly to increase its power. The *platten* L is screwed on to the under surface of the spindle; the *table* M has slides underneath, which move *in* the *ribs* N, N, instead of *upon* them, as in the old presses, and is run in and out by means of girths affixed to each end, and passing round a drum or wheel O. As the platten is of considerable weight, the workman would have to exert much strength in raising it from the form after the impression has been given, were not a balance-weight P suspended upon a lever and hook at the back of the press, which counterbalances the weight of the platten, raises it from the form, and brings the bar-handle back again, ready for another pull. These are the principal parts of the machinery whereby the impression is given, and are sufficient to give the general reader, with the aid of fig. 5, an idea of the mechanism of the Stanhope press. For the printer there are yet other appliances. At the right-hand end of the table is an iron frame Q, moving freely upon pivots, so as to fall upon the table, or rise until stopped by what is called the *gallows* R; this is covered with parchment very tightly stretched, and is then called the *tympan;* upon the tympan blankets are placed, which are covered by an inner tympan, and fastened by hooks; the whole forming a solid yet elastic and yielding surface, admirably fitted for impressing the paper upon the type (for this is its use), inasmuch as the surface of the parchment is soft and without grain, and readily receives the impression of the type, while the blankets give freely to every projection, without retaining any indentation. To protect those portions of the paper which are not intended to be coloured from ink or soil, there is at the upper end of the tympan another iron frame, of much lighter make, and also moving upon pivots, so as to fall upon the face of the tympan. This is covered with a sheet of coarse paper, and after an impression has been taken upon it, the exact size and form of the pages are carefully cut out therefrom, the parts left being an excel-

lent protection of the paper under them. This is called the *frisket.*

Such is the ordinary Stanhope press. A notice of the principle of many other excellent presses which have been since invented, and very extensively introduced, will be found in a subsequent part of this treatise. The manner of working is the same in all.

On the left front of the press stands the inking-table. This is made of iron, about four feet high, and three feet four inches wide; at the back is a solid iron cylinder, turned perfectly true, against which a thin steel straight-edge is made to press by means of levers and weights, thus forming a trough for the ink; of which, when the cylinder is turned round, it becomes covered with a thin film, its thickness being regulated by adjusting the weights on the levers. Against this iron cylinder the inking-roller (which will be hereafter described) is dabbed, and being rolled backwards and forwards on the table, the ink is evenly distributed over its surface.

It must be fully understood that printers' ink is a very different composition from that used for writing. It is of such consistency that if a small portion be taken up between the finger and thumb, when they are opened it will produce a thread of an inch or an inch and a half in length. Of all the materials used in printing this is the most important, and the most opposite qualities are required in it. It must be of excellent colour. Formerly excellence of colour was deemed to consist in an exceeding dark hue, not exactly black, but black enriched with a hue of the darkest blue or purple. This gave indescribable effect to the works for which it was used, a richness and intensity which it is impossible to describe, but of which the works of Baskerville and Bulmer, especially the *Milton* of the latter, afford the best specimens. *Now* we hold perfection to consist in the intensest black, and all the resources of chemistry and the arts have been sought to attain this end. It must stand for ever; but here we have miserably failed. Compare the productions of the old printers with those printed twenty years back. What a difference! The works of the Aldi and Elzevirs, of Plantinus, Caxton, Pynson, and Grafton, preserve their colour as intense as on the day they were printed; there is no yellowness or brownness, no foxiness; whilst the books printed from 1810 to 1820 are wretchedly discoloured. Where fine printing, however, has been required *and paid for*, the modern ink is no whit inferior to the ancient. Witness the works of Bulmer, Macklin, Ritchie, Bowyer, Baskerville, and others; but certain it is that the ink in general use twenty years ago was of very inferior quality. It must be perfectly mixed, and ground until it is absolutely impalpable, otherwise it will speedily clog the types and inking apparatus; it must adhere to the paper, and not to the type, or it will tear off the face of the former, and clog up the latter; it must be sufficiently thick; it must keep perfectly undried when in large masses, and dry very quickly when it is transferred to the paper. Few printers of the present day make their own ink, although some add ingredients which they believe to improve the colour or quality. Ink-making is a distinct business; and by the aid of machinery, capital, and exclusive attention to the manufacture, the ink now supplied is admirable in the qualities of being thoroughly mixed and ground, drying, blackness, &c.; but whether it will stand the test of time, time alone can show. It is an expensive article, the commonest book-ink being one shilling and sixpence per pound, whilst the usual qualities are two shillings and sixpence, three shillings, and four shillings per pound; those used for superior work are five shillings or six shillings; and those for cuts as high as ten shillings—though it is questionable whether, at the latter price, the consumer is not paying for a mere name.

Every manufacturer has of course his own secrets both of ingredients and process. The universal ingredient is the finest possible lamp-black; the great secret probably consists in the manner in which, and the material from which, this is made. There are vast buildings appropriated to the sole purpose of burning oil, naphtha, spirits, coal-gas, &c., to produce this black, which is collected from the sides, ceilings, &c., of the buildings; it is brought from Germany and many other countries; and no expense is spared to get the most superior quality. The next most important article is nut or linseed oil boiled and burnt into a varnish; then oil of turpentine, &c. The following receipts have been given. The first is the method used by Baskerville and Bulmer, and nothing can be better than the results:—

1. Fine old linseed oil boiled to a thick varnish, and cooled in small quantities, three gallons; a small quantity of black or amber rosin dissolved therein; the mixture then stands for some months, that all impurities may be deposited; after which it is mixed with the finest lamp-black, and carefully ground for use.

2. One hundred pounds of nut or linseed oil are reduced by boiling and burning one-tenth or one-eighth of its bulk, and to the thickness of a syrup, two pounds of coarse bread and several onions being thrown in to purify it from grease. Thirty or thirty-five pounds of turpentine are boiled apart, until, on cooling it on paper, it breaks clean, without pulverising. The former is poured nearly cold into the latter, and well mixed. The compound is then boiled again. Lamp-black is next thoroughly mixed with it, in quantity according to the ink required, and being well ground, the ink is then ready for use. Some add indigo, some Prussian blue, which considerably improves the colour; but these inks are so difficult to work, and so clog up the type, that the *improvement* is better let alone. The turpentine is added to give greater varnish, and improve the drying quality; but if the oil be old and fine, the quantity required is proportionally less.

3. Mr Savage, an admirable artist, denies that any ink can be depended on of the varnish of which oil is the basis; he therefore gives the following receipt:—Balsam capivi, 9 oz.; best lamp-black, 3 oz.; Prussian blue, $1\frac{1}{2}$ oz.; Indian red, $\frac{3}{4}$ oz.; turpentine soap dried, 3 oz. This ink is of beautiful colour, but appears to work foul. There can be no doubt, however, that the best and cheapest plan is always to purchase what is required of a proper ink-maker.

At the right front of the press stand the *bank* and *horse.* The bank is a deal table of some size; the horse is an inclined plane which stands upon the bank; upon it is laid the white paper properly damped for working; and as each sheet is worked, it is taken off the tympan and laid on the bank. There are two pressmen to each press, one of whom attends to the inking only, to ascertain the excellence of which, whenever he has a moment to spare, he turns to the worked sheets upon the bank, glancing his eye rapidly over each, to see that every part is of its proper colour, and that no picks or other imperfections mar the work; the other attends only to the press, and gives the impression. These men are paid by every two hundred and fifty impressions, called a *token.* Thus, if the number be five hundred, and the price $4\frac{1}{2}$d. per token, each man receives 9d. for the five hundred impressions of each form, and the cost therefore is,

Inner form, two men, two token, at $4\frac{1}{2}$d.............1s. 6d.
Outer form, do. do. do. ....1s. 6d.
3s. 0d.

The price varies with the size of the type and the form; with the quality of the paper and the ink; with the number, and the care required. Common work used to be paid for at $4\frac{1}{2}$d., good at 6d., superior at 7d., the very best at 8d., 9d., or even 1s. per token. But now the price is matter of agreement between the master and pressmen.

One of the pressmen, having received the forms after the final correction, lays the inner form, or that one which contains the second signature, upon the table of the press, and secures it in the centre by quoins; the other in the meanwhile pastes a stout sheet of paper upon the frisket frame, and then secures it upon the tympan. The form is then inked, and an impression taken upon the frisket, and the printed parts only being cut away, that which is left protects the paper from ink or soil. The puller now carefully folds a sheet of the paper according to the crosses of the chase, and laying it upon the form, opens it carefully, by which the paper is made to lie evenly upon the form, with the same margin with which it is to be afterwards worked. Having slightly wetted the tympan, he turns it down upon the form, and takes an impression, when the paper will be found to adhere to the tympan, and thus become a guide whereby to lay all the subsequent sheets, and therefore much care should be taken to lay it properly. They now choose their *points*, which are thin and narrow pieces of iron, having a short point or spur projecting from one end, and a shank at the other made to screw on to the tympan-frame, which must be done in such a manner that the spurs may fall into the grooves in the cross of the chase; because if they did not, they would be battered or broken at the first pull. It is advisable to make the inner form *register*, for it may be very difficult to correct any error in the furniture when the *reiteration*, or outer form, is laid on.

The puller now brings his paper from the wetting-room; for before any good impression can be taken the paper must have been damped, by rapidly passing it, one-fourth or one-fifth of a quire at a time, through water, and then allowing it to soak for two or three days under a heavy weight, until it is evenly and thoroughly damped; and laying a ream upon the horse, he takes a sheet, and placing it carefully over the tympan-sheet, closes the frisket over it, shuts both tympan and frisket down upon the form, which in the meanwhile his companion has inked (a process that will be described below), runs the table in under the platten, pulls the handle of the bar or lever over by his full weight, until brought up by the stop, at which moment the platten descends, and exerts a powerful pressure to the tympan, &c., upon the form, producing upon the paper a perfect fac-simile in reverse of the surface of the pages. The pressman now gradually releases his hold, the balance-weight raises the platten, the bar returns to its first position, the table is run out, the tympan and frisket are raised by the workman, and the frisket thrown up to the catch. The sheet is taken off the spurs of the points, which have been forced through it by the pressure, and the back of the impression is carefully examined, to ascertain that every part of it is just and even, which is the great test of the workman's skill and the excellence of the press. The first impression is, however, invariably defective: the parchment may have been thicker in some parts than in others, the blankets worn, or one of two founts of type may not have been of equal height, in which respect "the estimation of a hair" would produce a manifest imperfection, but which may be remedied by the thinnest possible tissue paper. The pressman now proceeds to *overlay;* that is, by pasting upon his tympan-sheets portions of paper of the exact size of the defects, thicker or thinner as may be required, to *bring up* the form; he overlays the faint parts of the impression; or if the defect be great, he places a part of a sheet of paper within the tympan, or, which is a much better plan, he raises the form, and pastes the paper under the defective part. If there be any small portion of undue prominence, or that "comes off hard," he rubs down a portion of the tympan-sheet with his wet fingers, or cuts it away altogether. Having, as he supposes, remedied all blemishes, he takes another impression, which he again examines with equal closeness, and carefully removes every remaining defect by the same method; and having at length satisfied himself, and his master or overseer, that the form is well brought up, the work is proceeded with, the inker taking off from the table with the roller or balls even portions of ink, which has been well distributed on its surface, and rolls or beats the form, being very careful that every part is equally inked; the puller taking a sheet and laying it on the tympan as before. They thus proceed until the whole number of the white paper is worked off; when it is a good precaution to count the heap, to ascertain that the number printed is correct. The form is now lifted from the table, and carefully washed with very strong lye. The outer form is then laid on and made ready.

The making ready of this form varies a little from the mode previously described. It has been stated that the spurs of the points penetrate the paper at the first impression. The holes thus made are the guides whereby perfect *register* is obtained; that is, whereby not only the pages, but the lines, are made to fall exactly upon the back of each other, any variation in this respect being a great defect in good book-work. The outer form, therefore, having been placed on the table in precisely the same position which the inner previously occupied, a printed sheet is taken from the heap, and laid upon the tympan with its printed face inwards, in such manner that the spurs of the points pass through the holes made by them in the working of the inner form, but of course the opposite way; and an impression is taken. If the pages do not back, the points are shifted until they do; or if the defect arise from the furniture of the form, such alterations are made in it as may be necessary. The impression is then brought up as before, and when all is ready, a thin sheet of white paper, called the *set-off* sheet, is placed over the tympan-sheet and under the points. It must be remembered that one side has been worked, that the ink has not yet dried, that the paper is still damp; therefore at every impression some portion of the ink will be transferred to or impressed upon the set-off sheet. When this has taken place in many impressions, some of the ink of the print will be re-transferred from the set-off sheet to the sheet then working, producing a most unpleasing blurred appearance, very perplexing to the eyes, and utterly destructive of the beauty of the presswork. To obviate this, the puller, after a few impressions, moves the set-off sheet slightly, and when it has become very black, takes it off, and replaces it with another. The pressman should be very attentive to this; and the master should not grudge ample supplies of set-off paper, for it is not destroyed, but, when dried, may be used again for the same purpose, or in other departments as waste paper. The form is now lifted, and carefully washed with lye, and the two are ready for the composing-room, where they are laid up, as previously described. Two good pressmen are supposed to do about one token, or 250 impressions, per hour of fair work. This, however, must depend entirely upon the quality of the work required; with small type, stiff ink, and many rules, the work is more slow, and paid for accordingly. The finest work is seldom paid for by the token, the pressmen being placed upon weekly wages, and allowed as much time as they require, the rapidity being at the discretion of the overseer. Frequently they are limited to a certain number per hour, often as few as fifty, the most careful inspection being given to every sheet by both pressmen, and continual attention by the press-overseer and other chief persons in the establishment. In such work the very best materials are employed. Instead of parchment, the tympans are covered with fine calico, or even silk; instead of blankets the finest broad cloth; picked blotting-paper for the thick overlays, the thinnest tissue-paper for the finer. It will readily be understood that in all operations of the press-room, where everything depends upon the skill of the workmen, there are infinite minutiæ, which it would be tedious, if it were even possible, to enumerate. Seven years' apprenticeship are not more than sufficient to educate a good pressman; it is the accumulated labour of a life to make a first-rate one: and, after all, excellence depends upon the native talent and ingenuity of the man himself.

The ink is distributed over the type either by balls or by rollers. The rollers are of modern use. The balls, which are such prominent objects in the representation of ancient printing-offices, and which form part of the armorial bearings of the printers' guilds on the Continent, were formerly made of sheepskins, with the hair taken off by lime, and formed into a ball with wool, gathered at all corners, and nailed upon a wooden handle. One of these was held in each hand; and a small portion of ink being taken, they were well beaten upon the inking-table, and then upon each other, until the ink was so evenly distributed over the whole surface, that if touched gently with the finger, the prominent lines of the skin would be blackened, whilst the channels would be left perfectly clean. The balls were then beaten over every part of the type, so that the whole surface should be evenly covered; an operation requiring much skill and practice. The skins were prepared and softened by the nastiest processes imaginable, which converted a press-room into a stinking cloaca. Thanks, however, to the observation and ingenuity of Mr Forster, a practical printer, and Mr Donkin, an engineer, this has been entirely done away, and a press-room now regales the nose with a warm scent of ink and paper, anything but unpleasant. This invention has been of the greatest consequence to printing. The printing-machine is said to be the handmaid of modern literature; and so it is; but without this, printing-machines were mere old iron and brass. Earl Stanhope had attempted to substitute skin rollers for skin balls; but his plan failed owing to the difficulty of preparing the pelts, and the inevitable seam, which left a broad mark upon the type. But the use of rollers, which in the hand-press would have been merely an improvement on a process in use, was a necessity to the printing-machine, and the complete failure of the earliest of these machines was in a great degree owing to the imperfection of their inking appliances. For many years the workmen in the potteries had used a composition of glue and treacle for applying colours to their ware. Mr Forster observed that this composition possessed every requisite for the use of the printing-office, and he immediately proceeded to form balls of canvas, with a facing of composition. They answered admirably, proved beautifully soft, distributed satisfactorily, kept clean, and were easily washed and purified if soiled. Some opposition was offered by the workmen; but the advantages proved so great that they were readily adopted by the masters, and speedily drove away for ever the nasty skins. The next step, however, was more important still. Mr Donkin observing the adaptability of the composition to casting rollers for printing-machines, devised moulds, by which he was able to cast cylinders without seam, and of somewhat greater tenacity than the original compound. The rollers answered perfectly for printing-machines; and there was little difficulty in perceiving that at the hand-press the roller might be advantageously substituted for beating by balls. They were accordingly introduced, and after meeting with some opposition, are now in universal use. They consist of a solid wooden cylinder, with a thick coating of composition cast in a metal mould perfectly true; through the middle of the cylinder passes an iron rod attached to a curved bar, upon which are fixed two handles; the roller revolving freely upon the rod. The pressman regulates the quantity of ink to be taken by adjusting the pressure of the straight edge against the cylinder at the back of the table, as above described; and according as that pressure is greater or less, the cuticle of ink on its surface is proportionately diminished or increased in thickness. Having taken off upon the inking-roller a line of ink, he distributes it carefully upon the table until the entire face is evenly covered, and then rolls the form, taking care that the whole surface receives its due proportion. If he does this lightly and steadily, there is no fear of the result; he cannot in rolling leave any part without ink; but it nevertheless requires some judgment. If there be any heavy titles or large type, he must roll that portion several times; if there be blank pages, he must take care that the roller does not sink, and so leave the pages in line with them slightly touched. The greatest judgment, however, is displayed in choosing the exact quantity of ink required for the form. If the type be small, the quantity taken must also be small; it must be very carefully distributed, and the form rolled many times; for if the quantity be too great the type will become clogged, and if too little, the colour will become faint. The pressman must from time to time examine the sheets as they are printed, and in working the reiteration, turn up the corners of the sheets to see that the colour corresponds with that of the inner form, detecting with quick eye every defect; and he must be particularly careful that for every sheet of the same work he takes the same quantity of ink, so that the book when bound may present an even and beautiful colour, every bold line being perfectly covered, and yet every fine stroke clear and distinct. This can only be effected by careful distribution and repeated rolling, with nice judgment as to the quantity of ink to be taken.

The sheet having been thus worked off, the printed paper is taken away by the warehouseman, and hung by the boys upon poles stretched under the ceiling, by means of a *peel*, which is a handle with a broad end, upon which a quire or two is hung at a time, thence transferred to the poles, and distributed in portions of four or five sheets. Here they hang a day or two, until the ink and paper are perfectly dry. This should be a gradual process, for if by artificial heat the drying is hurried, a skin will be formed upon the surface of the ink, which will prevent that underneath from drying; the work will look very well until it is pressed or bound, when the skin breaks, the ink spreads, and the sharpness of the impression is entirely destroyed. When perfectly dry the sheets are taken down and laid in heaps upon the gathering-board, each signature separately; thus, first, a heap, say 1000, of B, then C, D, E, F, and, lastly, the title-sheet A. The boys then take one sheet from each heap; consequently, when they have got to the last signature, each boy has gathered one complete copy of the work. These are laid upon one another at the end of the gathering-board in such a manner that each book is perfectly distinct. The warehouseman then takes away this heap, and with a collator (a needle inserted in a handle) goes over the whole with great rapidity, ascertaining that no sheet has been carelessly omitted, and that more than one of each signature has not been taken. The books are then folded down the middle, counted out in tens, thirteens, or twenty-fives, and tied up in bundles of convenient size. The process of printing is thus complete, and the work is ready for the binder.

Works of finer description, indeed most works of the present day, are submitted to another process after they have been taken down from the poles, viz., hot or cold pressing, which very much improves their appearance. In cold pressing the sheets are placed one by one between glazed boards, which are sheets of coarse material pressed and glazed on both surfaces by burnishing on a steel plate with a steel ball. The heaps are then placed in a hydraulic press, with cold iron plates at small intervals, and the whole is subjected to considerable pressure for some hours; they are then taken out, and the sheets extracted from the boards, when the indentations consequent upon the working will have been all pressed out, the roughnesses of the paper smoothed out, a slight gloss given to the ink, and the whole will present a very agreeable smoothness to the eye and the touch. Hot-pressing is used when the paper is very stout and the ink strong. The sole difference is, that the iron plates are heated until they can hardly be touched. The effect produced is much greater than that by cold pressing; the whole surface of the paper is perfectly glazed, and the ink absolutely shines; but the effect is not so agreeable to the eye; it is too glossy. A machine of great power has been invented for superseding the use of glazed boards and the hydraulic: in this machine the sheets are placed between two plates of copper or zinc, and passed in rapid succession between two hard steel rollers, and come out more perfectly smoothed than by the ordinary hot or cold pressing. As these processes set the ink and also make the books lie perfectly flat, they render much beating by the binder unnecessary, which is a great advantage, as the beating causes the ink to set-off upon the opposite pages when the work is recently printed. The glazed boards must be often cleaned by rubbing with waste paper, or they will soil the sheets placed between them. Every printing-office of credit should have an hydraulic press and glazed boards; for it is incredible how much smartness pressing gives to the work, and how greatly the warehouse work is facilitated by the readiness with which the hydraulic is pumped up, and by its great power. A press of eight-inch ram will be found sufficient for most purposes; but where much hot and cold pressing are required, one of ten-inch ram will prove cheapest, because, from its immense power, a few hours are sufficient to give the requisite surface, and the press may therefore be filled twice or thrice a day.

Wood-blocks are very often worked along with the common type. The block, having been carefully reduced by the engraver to the exact height of the type, is placed in the composing-stick, and justified to the width of the page; it is then made up along with the other matter in its proper place. When laid upon the press for working, and an impression of the form has been taken, the pressman examines with great minuteness whether it stands well with the type; if not, the form is unlocked, and paper placed under it if it be too low, or under any corner that may be lower than the rest; if the block be too high, it must be scraped or filed at the bottom. The artist in wood contents himself with producing his lights and shades by cutting his lines in greater or less degrees of fineness upon a plane, leaving to the printer the task of producing the required effects by a tedious process of overlaying; so that the pressman becomes to a certain extent an artist, and must have a good eye for perspective and for the proper adjustment of tints. These effects he produces by careful and skilful overlaying. But Bewick and some other eminent engravers, instead of imposing this tedious process upon the pressman, used to cut away the parts of the block intended to appear light before engraving them; and thus, by repeated lowering and rounding, they so regulated the lights and shades that the cut left their hands in a fit state to be worked. This process was, however, very costly, and has been discontinued by modern artists. In machine-printing, to prevent the loss that would be incurred if the machine were to stand still during the operation of bringing-up, the machiner, some time before the sheet is laid on, takes an impression of the cuts, and by overlaying and other processes, so prepares them that they require very little additional work when the forms are laid on. Where it can be managed, the cuts should be worked in the outer form, to prevent setting-off and the impression of the reiteration upon them. The cuts may then be worked with the type without any other care than that of keeping them clear from clogging or picks. When done with, they must be very carefully cleaned with spirits of turpentine and a brush.

The working of woodcuts by themselves, as illustrations of works, differs from type-printing in no other respect than in the superior materials and skill required. The woodcut must be imposed in a chase, and locked up upon the table of the press, which is generally a smaller one than that used for ordinary printing, of most excellent construction, and in good order. The tympans are, as before stated, often of silk or cambric. For the inking, balls are preferred to rollers. The greater opportunity for manual skill offered by the former enables the pressman to exercise an artistic judgment which is not possible when rollers are used. The ink is generally brayed out by a muller on a slab.

There are in London, and probably in the larger provincial cities, parties who make an especial business of the manufacture of composition balls and rollers, which they supply to printers upon payment of a rent. The skill and experience of these persons enable them, as must be the case in every instance where a manufacture engages exclusive attention, to supply a much better and cheaper article than could be manufactured by any individual whose engagements are varied; consequently there are not many printers, either in town or country, who do not avail themselves of these opportunities. The rent is paid for each roller required, and by the quarter; that is to say, if a printer employs six presses, and consequently six rollers, he pays for six rollers, the manufacturer engaging to supply him with as many changes as he may require from their getting out of order or being injured; in fact, to keep him supplied with six rollers in good condition. The rent for a common press-roller is the moderate sum of six shillings per quarter: they are sent into the country in boxes fitted for the purpose. There are, of course, situations in which it is not easy to obtain a regular supply of the necessary article, and in this case the printer may very easily make them for himself; but the expense of the utensils is so great as to exceed the usual rent for years. They consist of the following:—For rollers, a hollow cylinder of iron, the bore of which must be most accurately turned and well polished; this mould consists of two semi-cylinders closely fitted, and brought into contact by screws along the sides and collars at the end, and a head is made to fit into the lower end. The core, a wooden or iron cylinder, upon which the composition is cast, is held in the centre of the bore by means of a star, through the radii of which the composition flows. For balls are required a concave mirror of about half an inch cavity, and a board of the same size and of a quarter of an inch convexity. A kettle for melting and mixing the composition is also required. This is made double like a glue-pot, fitting exceedingly close, and with a small orifice for the escape of the steam from the hot water between the two; and the inner vessel should have a large lip. The recipes for making the composition vary, and this appears to arise from the different circumstances under which it is made. The ingredients are but three, and these easily purchaseable, viz., fine glue, treacle (not that procured from the sugar-bakers, which is adulterated, but the best from the sugar-refiners), and a small quantity of carbonate of barytes, called in commerce Paris white, or of carbonate of soda. The first two ingredients are quite sufficient with a little skill. The following are good recipes:—

1. Two pounds of glue to one pound of treacle.
2. Two pounds of glue to three pounds of treacle.
3. One pound of glue to three pounds of treacle and a quarter of a pound of Paris white.

(Sugar is sometimes used in lieu of treacle, and is said to make the composition firmer.)

Soak the glue in water until it is soft; then place it in the inner vessel, and boil quickly, until the glue is thoroughly dissolved; add the treacle, mixing it well, and let it boil for an hour or more; then sift in the Paris white, but do not stir it violently, or the mixture will be full of air-bubbles, which are destructive to the roller or ball. Rub the mould slightly with a rag dipped in thin oil, taking care that no globules and streaks remain upon the surface. When the mixture is ready, pour it gently between the radii of the star, so that no air be detained within the cylinder, until the mould be filled; allow it to set, and then take it from the mould, cutting off the superfluous portion with a string. When the roller has been hung up twenty-four hours it will be fit for use. Owing to the rapidity of the printing-machines recently introduced, the ordinary rollers have proved inadequate to the work; but improvements have been introduced into the manufacture which remedy the defect. The excellence of the new rollers is said to depend entirely on skilful manipulation. The ingredients are the same, but great experience is required in the choice of the glue, the proportion of the ingredients, the mixture, and the heat applied. In making balls, having oiled the mirror, pour the composition upon the centre, and having allowed it to spread itself, lay over it a piece of coarse canvas, place the board upon it, and lay weights upon it to press it down; it will consequently be found that the composition face of the ball will be slightly thicker in the centre than at the edges, which, besides being a convenience in the working, will allow it to be *knocked up* with much facility, which is done in the ordinary manner. These balls and rollers are very easily kept in order: if they are too soft, cold water will harden them; if too hard, warm water will soften them. When not in use they should be covered with refuse ink, and hung up in a room of even temperature, and carefully scraped with a palette-knife before use. They should not be cleaned with spirits of turpentine, as that will give them a hard surface. These rollers will be fit for use for a long while if attention be paid to them; and when spoiled, the composition may be repeatedly melted down, and, with an addition of new materials, will make as good rollers as before. When the proper apparatus is wanting, small balls for woodcuts or single pages may be made upon an earthen palette, or even upon a smooth dinner-plate.

A new process has recently been patented by Messrs Harrild for the manufacture of composition rollers, which enables them to resist the friction of the fastest machines even in the warmest weather, and to continue in working order for a much longer period than those at present in use. They are also but slightly affected by atmospheric changes. These are great advantages for the fast newspaper machines, and for country printers who have not the same facilities as the printers in the metropolis for changing their rollers when out of order. The principal difference in the new process is, that the glue is liquified without any admixture of moisture, the condensed steam which floats on the surface of the glue being entirely drawn off by a syringe.

STEREOTYPING.

Stereotyping is a mode of making perfect fac-similes in type-metal of the face of pages composed of moveable types. Letterpress printing being a very expensive process, the price of books consequently high, and the heaviest expense consisting in the composition, the printers of the Continent very soon set up the entire of such small works as were in constant demand, and thus were enabled to sell them at little more than the cost of paper and press-work. Some works of very great extent, especially Bibles and prayer-books, were kept standing by the privileged printers. This, however, was exceedingly expensive, as the cost of the type would be very great; the forms would occupy much space in storing, and be liable to continual damage from the dropping out of letters, from batters, and other accidents to which they would be unavoidably exposed. Some method, therefore, by which all or some of these disadvantages might be remedied, became desirable. About the beginning of the eighteenth century, Van der Mey, in Holland, sought to avoid this liability to accidents, by immersing the bottom of his pages in melted lead or solder, and thus rendering them solid masses: "c'est une réunion des caractères ordinaires par le pied, avec de la matière fondue, de l'épaisseur d'environ trois mains de papier à écrire;" therefore the mass together would be somewhat less than the height of our type. It is not very easy to imagine how they contrived to make the backs of these blocks of such evenness as to produce anything like a good impression; but Dibdin says that *the book* is very handsome. The same process was followed by a Jew of Amsterdam, in printing an English Bible; but he was utterly ruined by his speculation.

Some time before the year 1735 there is sufficient evidence that the French used casts of the calendars placed at the commencement of church books. These plates are thus described by Camus: "It (one of the plates) is formed of copper, and is three inches and a half long by two inches broad and one-seventh of an inch thick. From the roughness of the casting, it has evidently been made in a mould formed of sand or clay." After the plate had been cast, the back of it had been dressed with a file, in order that it might bear equally upon a block of wood to which it had been attached.

Who really invented the art of stereotyping as at present practised (and after all, he who finds out the efficient *modus operandi* is the inventor of the art, though he may not be of the principle) is, like the inventor of the parent art, a matter of some controversy, which has been carried on with more vigour than the subject merited. It seems however most probable, when all assertions are weighed, that William Ged, a goldsmith of Edinburgh, deserves the credit. According to his statement, being in 1725 in company with a printer, they lamented the want of a good letter-founder in Scotland; and the printer asked him whether he could do anything to remedy the inconvenience. He immediately answered, that it would be more easy to cast plates from pages when composed in moveable type; and he undertook to produce, and very shortly did so, a specimen cast on his new plan, and not long afterwards made arrangements with a capitalist for the advance of the requisite funds. The latter failing to perform his part of the engagement, Ged made a similar contract with a London stationer, in conjunction with whom he made many attempts; but being repeatedly thwarted in perfecting his plans, he separated from his partner, and made proposals to the universities and the king's printers for the stereotyping of Bibles and prayer-books. These all entered into the scheme with eagerness, and some works were produced from plates quite equal to the ordinary printing of the day. Nevertheless, so much ignorance and prejudice prevailed amongst the workmen and other interested persons that Ged was obliged to abandon the undertaking. He entered into several subsequent arrangements, in which he was equally unsuccessful; a type-founder, in particular, causing so much opposition that the invention made no progress. Ged died before he had met with much encouragement; and his son was equally unsuccessful, although, as the practicability was made more manifest, the very parties who had rejected his plans subsequently made extensive use of his plates. What was Ged's method of stereotyping is unknown, as he kept it private; nor did he fully communicate the secret to his partners.

Fifty years afterwards Mr Tilloch made a similar invention; but from private circumstances the design was laid aside, not, however, before several volumes had been printed from his stereotype plates at the press of Mr Foulis.

Some years after this, Lord Stanhope engaged an ingenious London printer, Mr Wilson, to prosecute the invention; and after many trials, the noble lord's ingenuity succeeded in bringing the invention to practical use.

When a work is expressly intended to be stereotyped, the spaces, quadrats, and leads generally used are somewhat different from those commonly employed, being cast of the same height as the stem of the letter, in order that the base of the plate may be more solid and of uniform thickness. When low spaces, &c., are used, plaster is poured upon the face of the type to fill up the interstices, and just before it sets the superfluous plaster above the stem of the letter is removed by a brush, which damages the face of the type not a little. The page is composed in the ordinary manner, and very carefully corrected; it is then imposed in a small chase with metal furniture, and the whole is placed within a moulding-frame, somewhat less than half an inch higher than the type. The surface of the type is then rubbed with a soft brush holding a small quantity of very thin oil.

The plaster of Paris (gypsum) of which the mould is formed is of the finest quality, and may be purchased ready prepared. Having been carefully mixed with water to the thickness of cream, a small portion is gently poured upon the surface of the page, and softly worked in with a brush, care being taken that every part is fully covered, and that no air-bubbles remain. Then a larger quantity is poured on, and spread over the previous layer without disturbing it; a straight-edge is then passed over the moulding-frame, clearing away the superfluous plaster, and leaving that within the frame of uniform thickness. It is then left to set. When sufficiently dry, the moulding-frame is raised, and the mould with it, from off the face of the page; the mould is then dressed, and placed in a heated oven until it be perfectly dry, and raised to an adequate temperature for the casting. The oil with which the page is rubbed prevents the plaster from adhering to the type.

The melting-pot is a square vessel of iron about two inches and a half deep, having a separate lid, of which the four corners are cut off, the inner face being turned true, but the outer face hollow towards the centre. A floating plate, of which the upper surface is turned, is placed at the bottom of the pot. Over the melting-pit is a crane with a rack, upon which a pair of nippers are made to run. These lay hold of ears upon the melting-pot, closing with its weight, and opening when relieved. The metal does not differ from type-metal, and must be sufficiently fluxed to flow easily, but not made too hot, or it will prove brittle. The melting-pot having been heated in the same oven with the mould, and consequently to the same temperature, the latter is placed within it, the face being turned down upon the floating-plate. A bar or other piece of iron is screwed down upon that part of the lid which is turned hollow; and the whole being suspended by the rack and crane, is swung over the melting-pit, and gradually let down into the metal, which flows gently into the pot through the openings left at the corners. The metal flowing slowly in gradually expels all the air; the mould immediately rises to the inner surface of the lid; the floating-plate, being specifically lighter than the metal, rises also to the edge of the mould; consequently the metal which has run in between is of the exact thickness of the depth of the mould, the upper surface being the field upon which are the casts of the type, the under surface the smooth face of the floating-plate, and the rest of the melting-pot being filled with metal. The pot is allowed to remain immersed ten minutes or a quarter of an hour, that is, until the air is supposed to be perfectly expelled. It is then drawn up, and swung to a board resting upon a trough of water, and there allowed to cool. The cooling is a process requiring much care and attention. It is obvious that unless the whole mass cool equally, the plate will be warped, and consequently spoiled; it is equally clear that the heat will more readily radiate at the corners, and consequently that the centre will remain fluid after the other parts are set, and that the contraction must be unequal. This is provided against by the lid having been turned hollow in the centre, and it will therefore allow the metal under it to cool more rapidly. The mass having been turned out from the pot, the metal under the plate is separated by a smart blow or two of the mallet; the floating-plate will be readily disengaged, and the mould be removed from the cast. Some defects will invariably be found in the new plate; but these are removed by the picker, who goes carefully over it, clearing away the picks from the face of the letter, and deepening the larger white lines with a graver, that they may not blacken in working at press; for it must be remembered that the quadrats and spaces used in stereotyping are higher than those in moveable-type printing. If the face of the plate has cooled evenly, and it is in other respects a successful cast, it is placed, the face inwards, in a turning-lathe or planing-machine, and the back rendered a plane parallel to the face; the margins are then squared, and the edges flanched. The plate is now ready for use. If any errors or batters occur in the plates, they are cut out, and the corrections made with moveable type let in and soldered at the back.

A great improvement in the stereotype art was a number of years ago introduced by Mr Thomas Allan, printer in Edinburgh, into his establishment, by which a number of plates are cast at once, whilst the risk of broken casts is considerably lessened. This is effected by means of a pot sufficiently deep to contain moulds placed in a perpendicular position. The pot is an oblong square cast-iron box, widening towards the mouth, and having placed inside, at each end, a wedge-like block, of which one face is parallel to the side, while the other is perfectly vertical. On the vertical side are perpendicular grooves, at distances rather greater than the thickness of the stereotype moulds. Into these grooves are inserted plates of malleable iron, by which the interior of the box or pot is partitioned into spaces sufficiently wide to admit with ease the plaster moulds. The moulds, when baked, being inserted into these spaces, a cross bar of metal is placed over the top, instead of a cover, which serves to prevent the moulds from being raised by the liquid metal flowing beneath them; and it is then suspended upon the crane, and dipt into the metal-pit in the usual way. By this method not only are the moulds saved from all risk of breaking by being placed horizontally and pressed between the two broad surfaces of a float-block and cover, as in the method of single-page casting, but a number of plates are produced at one cast, and thus additional celerity is combined with greater certainty of sound plates. The plates of the *Encyclopædia Britannica*, which is the most extensive work ever stereotyped, have been for the most part produced by this process, in pots containing each five moulds; and it is especially advantageous for large plates, the risk of breakage by the old method increasing in a greater ratio than the increase in the size of the page.

The plates are sometimes screwed down at the corners upon blocks of wood, the height of which is the difference between the thickness of the plate and the height of the type. This answers very well for jobs and standing advertisements; but for ordinary book-work it is usual to have the blocks formed of several separate pieces of mahogany furnished on one side and at one end with brass or iron catches (let in and screwed to the blocks), the upper part of which is turned over so as to take hold of the flange of the plate. But as wood is liable to warp and to other accidents, a plan has recently been devised of making hollow blocks of type-metal of the requisite height and of different sizes, by means of which pages may be easily composed to any required size, the plates being fastened on by brass holders. At a small expense, once incurred, the stereotype printer may furnish himself with blocks capable of being made up to suit works of any measure.

There are many smaller instruments requisite, which it is unnecessary to mention. The founder requires some practical skill, which, however, it is not difficult to acquire; and the excellence of the casts will depend upon his personal knack and observation. The best metal for stereotyping is composed of new metal and old type in moieties. The price of prepared metal is about 28s. per cwt. The following, however, are proportions which may be used when the prepared metal cannot be procured:—

1. From five to eight parts lead, one of regulus, one fiftieth of block-tin.
2. One seventh of pure regulus, six sevenths of lead. The best lead is that which comes from China, in the lining of tea-chests.

The mixing of the metals is exceedingly injurious to the workman, and should be avoided wherever it is possible. The foundry should be thoroughly ventilated, as the fumes from the melting-pit, and the moisture and smell of the drying oven, are very noxious.

In some cases stereotyping is of great advantage; but chiefly in books of numbers, in which it is of the utmost importance that every figure should be correct. In this case the proofs must be read again and again, until the correctness is unquestionable; when once stereotyped, there is no fear of alteration from the error of compositors or carelessness of readers, but the book remains the same for ever. Such works also are most expensive in getting up, and the cost of composition very much exceeds that of stereotyping. Books of logarithms may be especially mentioned, tables of longitude, indexes to maps, and other works, which being once written, remain unchangeably the same, such as ready reckoners, interest tables, &c.; or when it is found expedient to have duplicates of the work where large numbers are required, and it is necessary for speed to work on double-sized paper, the cast and the moveable type are imposed together, and are worked side by side at the same moment, producing two copies instead of one. There is also another advantage, for the stereotype remains without further expense for another edition; again, where it is expedient to send duplicate plates to other countries to be worked.

Woodcuts may be stereotyped with great advantage; for a small cut which has cost several guineas to engrave may be multiplied indefinitely, and at a cost of only a few shillings.

No printer should stereotype by the common process who wishes his type to be a credit to his house. The wear of the type in casting is very great, especially when low spaces, &c., are used; the gypsum is at best a fine powder, and grinds away the edge and face of the letter when rubbed in with the brush, in a frightful manner. The letter can never be entirely freed from the plaster, and will present a very dirty appearance ever after. The wear of a fount of 1000 lb. weight, returned six times from the foundry, is greater than would occur in six years' constant fair usage; besides which, the high spaces, quadrats, and leads, are all extra expenses, for which the economical bookseller makes no remuneration whatever.

The plan of stereotyping Bibles and prayer-books has been nearly abandoned, and the entire sheets are kept standing in moveable type, at a great expense, by the Queen's printer, and the universities of Oxford and Cambridge. Before every edition, however, is worked, each sheet must undergo a careful reading, in order to guard against accidents which may have occurred since the last edition.

Such is the process of stereotyping at this time in common use, and which will probably continue in practice in provincial and colonial printing-offices, by reason of the readiness of the materials and the knowledge now acquired by the workmen.

A greatly improved method has, however, been recently introduced by Messrs Dellagana, by which all the inconveniences incident to the existing system are obviated. The page is composed with the ordinary spaces, leads, &c., and there is therefore no additional charge for composition; the destructive tampering with the face of the type is avoided; the plaster-mould is not required; and there is no necessity for re-imposition, as the new moulds can be taken from the pages as they are imposed in the chases; and the forms can be returned to the printer within an hour from the time of their being sent to the foundry. So great are the resources of this invention that the largest or the smallest pages can be cast with equal facility, and either plane or curved to suit the periphery of cylinder machines. The pages, for instance, of *The Times* newspaper are each cast in a single plate, in a curved form to fit the cylinders of the great machines used in that establishment. The following is a brief account of the process:—

A page of a newspaper or a sheet of bookwork (as imposed), carefully cleaned and perfectly dry, is laid on an iron chest previously filled with hot water. A fine brush, having the whole of its surface slightly anointed with olive oil, is rubbed over the face of the type to remove any picks or other impurities from the pages, which are then ready for moulding. A substance, in appearance resembling two or three sheets of wrapper-paper pasted together, of a soft and pulpy nature (the matrix), understood to be composed of an earthy material very finely ground, and afterwards felted together, and which is not affected by heat, in a damp state, is laid smoothly on the face of the type, and carefully beaten in with a brush until every letter is indented into this substance, and the matrix is thus formed. The type, with the matrix unremoved, is taken to a press and subjected to a steady pressure, continued for two or three minutes. The matrix is then removed from the type, which may now be returned to the printer. Not more than ten minutes is required for these operations. The matrix is next laid upon a plate heated to 200° or 300°, and covered with a piece of flannel (as a non-conductor of heat and an absorbent of the moisture generated in drying) upon which is placed a thin metal plate of the dimensions of the page or form, to keep the matrix flat. It remains on this hot plate about two minutes, and is then ready for casting. The matrix, with its face upwards, is now placed in a "register" flat or curved, as the plates are required to be plane or convex. The register is formed of two iron plates, the inner surfaces of which are accurately planed; these plates are joined together by hinges at the further end. The matrix is placed, face uppermost, on the lower of these plates, and is secured on three sides by an iron guage, which varies in height according to the intended thickness of the plate about to be cast. The upper plate is closed over, and the two, inclosing the matrix, are firmly clamped together by an iron bar which passes over, with a screw in the centre, which presses the two plates upon the guage. The register swings upon trunnions; and thus prepared, is turned into a vertical position, and the metal, at a temperature of 500°, is poured in through a mouth. In one minute the metal is set sufficiently hard to bear removal, the register is brought back to a horizontal position, the upper plate is thrown back, and the cast and matrix are taken out and placed (the matrix uppermost) on an iron table, which is flat or curved like the register, otherwise the cast in cooling would contract or spring, and its flatness or curvature would not be preserved. The matrix may now be carefully lifted off, and, if required, again placed in the register for another cast.

The curved casts for newspapers are fixed on the cooling-table by four screws, and the dressing is performed by a tool on the lever principle, which cuts off the flange or waste piece of metal at the top of the page, and bevels it at the same time. For book-work, the under surface of the cast is planed, as in the ordinary mode. A little chiselling is required to lower the white and break lines, to prevent their blacking the paper when worked. The casts obtained by this process are remarkably true, and require little "bringing up." The matrix is uninjured by the casting, and may be used again for any number of casts, or preserved for future use. The power of multiplying casts from the same matrix is of immense advantage where large numbers are required to be printed in a short space of time. As before stated, a matrix and the first cast may be obtained in less than a quarter of an hour, and several subsequent casts will not require more than five or six minutes each. In half an hour, therefore, several machines may be at work simultaneously.

It is of course not necessary that any cast should be taken from the matrix; and therefore when a second edition of a book is doubtful, the matrix only need be made, and may be kept until required, at a cost of not more than one-third of a casting; and when used, may be put by without inconvenience, and another cast taken when the first is worked out or injured.

In book-work also this process will be found of great advantage, as compared with the charge for re-composition. The matrices of a work of 500 pages would occupy no more space than a ream of demy, and not weigh more than 10 lb. They will remain unchanged for years if preserved free from damp or water.

The cost of casts by this process is about 10 per cent. less than by the ordinary mode; and the proportions of lead and regulus used in the composition of the metal are those given above in recipe No. 2.

The great excellence of the imperial Austrian printing establishment in the art of stereotyping should not escape mention. In the Exhibition of 1851 were some magnificent moulds taken from type by the electrotyping or galvano-plastic process. From these moulds other copies in relief were obtained by doubling the process, which are stated to produce beautiful work; or casts in type-metal could be taken of great perfection. A curious specimen was also exhibited, the work of the Rubeland ducal foundry, of a stereotype-plate of cast-iron.

OF POLYTYPAGE, AND OTHER METHODS OF PRODUCING PRINTING SURFACES ON METAL PLATES.

Many considerable improvements in stereotyping are to be ascribed to French artists; but stereotyping has never been a favourite with them, and they have rather exerted their inventive talents in a series of experiments which may be classed under the general name of *polytypage*.

In 1780 Hoffman, a German residing in France, not satisfied with his success in stereotyping, made many ingenious experiments in polytypage. Whilst he was thus engaged, a practical printer named Carez discovered a method which Hoffman afterwards pursued. The page, after being composed in the ordinary manner, was attached, with the face downwards, to the under side of a heavy block of wood, suspended from a long beam. Immediately under the page was an anvil, whereon was a tray of oiled paper into which the workmen poured a portion of type metal, attentively watching the cooling. When the metal was on the point of setting, the page, block, and beam, were brought down with a very smart blow, forcing the face of the type into the setting metal, and producing a very sharp matrix; which again was made to take the place of the type upon the block, was struck in a similar manner upon the fused metal, and thus produced a perfect and excellent polytype plate. This having been properly dressed at the edges and back, was affixed to the usual wooden raiser and made type height, and might be printed separately or in conjunction with moveable type. Several casts might be made from the same mould. This process was designated *cliché*.

Ign, a native of Alsace, who settled in Paris as a printer in 1784, availing himself of the discoveries made in the art of stereotyping, endeavoured to extend them by inventing logotypy, or the art of uniting several characters into a single type. He printed on solid plates several sheets of his *Journal Polytype*, and advertised Father Chenier's *Recherches sur les Maures*, 3 vols. 8vo, as a polytyped book; but being deprived of his printing-office in 1787 by a decree of the council, he was prevented from executing his design.

In 1791 M. Gegembre made considerable improvements in the art of polytyping in printing the fifty-sous notes of the Caisse Patriotique. He caused the whole print of the notes to be engraved in relief upon a plate of steel, and this engraving he pressed into a plate of copper, from which polytype casts were taken. Any number of these casts could be taken from the copper mould, and if by chance the copper mould became injured, a new one could be readily made from the steel engraving.

When the revolutionary government commenced issuing assignats, it became necessary to have an immense number of plates to work the enormous quantity required of these documents. A design having been approved of, artists were employed to engrave *three hundred* fac-similes. Of course, if three hundred so-called fac-similes could be engraved, other artists would find no difficulty in engraving another hundred, nor could even the bank-officers tell which document was printed from a forged fac-simile and which from the plates engraved by their authority. The consequence was an utter want of confidence in the government paper. To remedy this, the committee of assignats caused many experiments to be instituted for the production of plates which should be not only imitative and similar, but *pro re* identical. The plan adopted was the engraving a plate *in intaglio* on steel, from which copper matrices were obtained *in relief*. From these perfect fac-similes of the original engraving were struck and were worked by the roller-press in the manner of copperplates. But it was a great defect in this process, that the air compressed within the hollows of the letters frequently destroyed the form in the reproduction. Upon the suppression of assignats this establishment was broken up; but some of the plates and matrices are preserved in the public repositories of France.

Polytyping, as now practised in England, is confined to the production of casts from metal plates in intaglio and from woodcuts. Instead of the cumbrous machinery employed by Carez, a fly-press is used, the woodcut is fixed upon what may be called the platten, and a tray containing semi-fluid metal is placed upon the table of the press immediately under the cut to be matriced. By a slow motion the cut is impressed into the metal, and an intaglio matrix is produced. The matrix is then attached to a drop stamp to perform the *cliché* process, and by the rapid descent of the stamp with the matrix attached into a tray of molten metal, a polytype in relief is obtained. The type-founders have adopted this process for the production of casts of their ornamental designs; and Mr Bramston has practised this mode so successfully that he is able to take fac-simile polytype casts of the most elaborately-engraved woodcuts, without in the slightest degree injuring the original.

A method of producing raised surfaces for the purposes of printing has of late years been extensively used in Paris and London, chiefly for forming maps and rough designs

Polytypage

for the cheap illustrated press. The art is of French origin, but has been patented in England. In a patent granted in 1853 to Mr Vizetelly it is described for "improvements in producing plates for printing surfaces, by which the manipulatory process of engraving is superseded."

A plate of highly-polished zinc, copper, or steel is thoroughly rubbed over with very fine pounce powder moistened with water, and then with a soft dry piece of linen it is again rubbed until no greasy appearance remains on the surface, which is now in a fit state to receive the transfer.

Where the engraving has been recently printed, say within a month, the transfer is thus effected:—The print is soaked for five minutes in a flat dish containing a liquid composed of seven parts of water, one of azotic acid, and six drops of phosphoric acid. It is then taken out and placed between two sheets of blotting-paper, to absorb the superfluous moisture, after which it is laid on the prepared plate and covered with a sheet of soft paper, and subjected to the strong pressure of the lithographic press. When the transfer is thus effected, the plate is washed with a sponge moistened in a solution of gum arabic, slightly acidulated with nitric acid; this preparation having remained on the plate for five minutes, is sponged off with clean water. While the plate is still wet, a lithographic roller charged with ink composed of bitumen of Judæa, powdered very fine with a muller and mixed with linseed oil, is passed over it. The linseed oil must be of the purest quality, and be boiled for at least an hour, and afterwards filtered through a felt bag containing some animal black. For zinc plates, lithographic transfer-ink and melted virgin wax, well mixed and ground together, must be substituted. When the plate is well rolled over with this ink, it will be observed that the transfer only has taken up the ink, the parts of the plate where the lines of the print do not occur having no power to take it up. While the ink is still wet, some resin, ground to an impalpable powder, is distributed over the plate with a piece of cotton wool or a camel's hair brush, care being taken that it adheres to the inked transfer only, and not to the other parts of the plate. The plate is now placed over a spirit-lamp, and gradually heated until it becomes lukewarm, in which state it is allowed to remain undisturbed for at least two hours; if expedition is not required, it will be better not to disturb the plate for twelve hours, as the resin and ink will then have thoroughly combined, and more completely protect the portions of the plate covered by the transfer from the corroding action of the acid, by which the surface in relief is produced. Before the plate is subjected to this "biting" process, it is necessary to cover its back with a varnish or other substance, to protect it from the action of the acid. When this is done, it is placed in a slanting position, and a liquid composed of nitric acid, diluted to about 4° Reaumur for zinc and steel plates, and to about 12° for coppers, to which is added a table-spoonful of spirits of wine to every half-pint of acidulated water, is applied with a clean sponge to the surface of the plate. This bathing is continued for a quarter of an hour, and pure water is then poured over the plate until the acid is entirely washed off. The plate is then again sponged over with the slightly-acidulated gum-water, re-inked, submitted to the action of the acidulated water, and washed with pure water as above described; and these operations are repeated four or five times, until the exposed portions of the plate are so much bitten away by the acid as to leave the transfer sufficiently in relief to be printed from.

The "whites,"—*i.e.*, the blank spaces in the engraving,—must be lowered or removed to prevent their receiving the ink in process of printing, and blacking the paper. This is effected by covering the surface of the raised lines of the transfer, and the sides also where practicable, with engraver's varnish, which is composed of bitumen of Judæa dissolved in essence of turpentine, with the addition of lamp-black to make it of a proper consistency, and allowed to stand two hours before it is used. The plate is then bathed with the solution of acidulated water and spirits of wine, and washed as before described; but in this operation a stronger solution is used, being 8° instead of 4°. Where the whites are very large, essence of spikenard (aspic) is substituted for essence of turpentine, or they may be lowered by scrapers or gouges, or cut out with a fine saw. Great care must be taken that the bitumen is entirely dissolved, and that the varnish is made of the proper consistency.

Printing for the Blind.

A raised printing surface being now produced, the plate is cleaned with turpentine and well rubbed over with charcoal, after which it may be mounted on raisers to type height, and used as a stereotype cast.

When an *old* print is to be transferred, it is treated in the manner commonly employed by lithographic printers prior to making a transfer, and which has been described in the article LITHOGRAPHY.

Anastatic printing is a process by which a print, whether from type or a copperplate, may be reproduced without drawing or engraving. The print is saturated with a strong solution of nitric acid; it is then placed between sheets of blotting-paper, and the superfluous fluid absorbed; after which it is laid, face downwards, upon a polished plate of zinc, and another placed over it. The plates are then passed between iron rollers, and subjected to great pressure. The nitric acid is thus squeezed out upon the zinc, except in those parts which are protected by the ink of the old print. The acid bites away the zinc, and a rough surface is produced, the protected parts continuing bright and unaffected. The plate is then wetted with a solution of gum in water. The corroded surfaces retain the fluid, while the unaffected portions remain dry. A roller charged with the ink used by copperplate printers is then rolled over the plate; the ink covering the dry and being repelled by the wet surfaces. This is repeated until the lines of the print are well covered with the ink,—a process which is rapidly effected if the ink of the original print is fresh, and has parted with a portion of its oil under the pressure of the rollers. Impressions may now be readily taken in the same manner as lithographic prints.

PRINTING FOR THE BLIND.

The invention of printing for the blind forms a new era in the history of literature. In European countries, one individual in every 1200 or 1400 of the entire population is blind, and in America one in every 2000. To open up to this large and unfortunate class such a source of profit and pleasure as reading could afford was long considered very desirable, and also very doubtful; but while, of late years, embossed books have very rapidly increased, it is exceedingly gratifying to find that blind readers have far more rapidly multiplied. The credit of this invention belongs to France. In 1784 Valentine Haüy printed the first book at Paris with raised letters, and proved to the world that those for whom such books were intended could easily be taught to read with their fingers. He seems to have caught the hint from a blind pianist of Vienna, who distinguished the keys of her instrument by the sense of touch. After many experiments as to the form of his raised letters, he at last chose a character a little approaching the Italic. A new institution was at once established,—*Institution Royale des Jeunes Aveugles*,—and Haüy was placed at the head of it. Twenty-four of his pupils exhibited their attainments in reading, writing, arithmetic, music, and geography, before the king and the royal family at Versailles on the 26th December 1786, to the very great delight of those high personages. In 1814, when Haüy was pen-

Printing for the Blind.

sioned off, Dr Guillié was chosen in his stead. This enterprising *directeur-général* modified Haüy's letters, and prosecuted the publication of embossed books with renewed vigour. Still, however, very little progress was made towards the extension of Haüy's system; and their books could only be read by those possessing a very delicate touch. In 1806 M. Haüy established schools for the blind in Germany and St Petersburg, but they have made very slow progress. It was in Scotland and the United States that improvements were first made in embossed typography. To Mr James Gall of Edinburgh belongs the merit of reviving and improving this very useful art. After canvassing every form of letter, he at last adopted his angular alphabet. Before 1826, when Mr Gall began his experiments, not a single blind person using the English language could read by embossed printing. On the 28th September 1827 he published *A First Book for Teaching the Art of Reading to the Blind*, the first book printed for the blind in the English language. In October 1834 this zealous individual published in a perfected alphabet *The Gospel by St John, for the Blind.* The text, which was embossed, and, unlike his former effort, printed not with wooden but with metallic types, consisted of 141 pages, with 27 lines on a page of 70 square inches. This book was counted a great improvement, but it was objected that the types were too angular. He afterwards printed a number of books with serrated edges. It is unquestionably to Mr Gall, more than to any other man, that the interest in the education of the blind was awakened throughout Great Britain and America. While Mr Gall was engaged in perfecting his plan in this country, Dr S. G. Howe, of the Perkins Institution, Boston, United States, was busily engaged in developing his system. In 1833 Dr Howe began, like Gall, by taking Haüy's invention as the basis of his system, and soon effected those improvements upon it which have given so wide a fame to the Boston press. He chose the common Roman letter of the lower-case, reducing it by cutting off the flourishes, &c., until it occupied but a space and a half instead of three. This alphabet remains unchanged. So rapid was his progress, that in 1836 he printed in relief the whole of the New Testament for the first time in any language, in 4 small quarto volumes, comprising 624 pages, for four dollars. More than twelve times this amount has now been printed, and seventeen of the American States have adopted Dr Howe's method.

The Society of Arts in Edinburgh awarded a medal, on the 31st of May 1837, to Dr Fry of London for the *invention* of an alphabet, which seems, however, to have been in use in Philadelphia since 1833. Mr Alston of Glasgow improved upon Fry's alphabet, by reducing the size of the letters, and sharpening the embossing. In 1840 Mr Alston published the entire Old Testament in 15 quarto volumes, of 2535 pages, and 37 lines to a page, in double pica type. Alston, in his just pride, designated this "the first Bible ever printed for the blind;" in which he was wrong, however, for Boston had claimed the honour years before. Some 70 distinct volumes have been printed by the Glasgow press; but since the death of Alston, on the 20th of August 1846, it has almost ceased to work. Since 1837 it has supplied England, Ireland, and Scotland with embossed books in Roman type. The best of all the arbitrary systems is that of T. M. Lucas of Bristol, who set it on foot about 1835, and which "The London Society for Teaching the Blind to Read" has been gradually improving since its establishment in 1839. In May 1838 "The London and Blackheath Association for Embossing the Scriptures" adopted the phonetic method of James Hartley Frere. A cheap plan of embossing or stereotyping was devised by Mr Frere in 1839. His books read from left to right, and back, after the ancient Greek βουστροφηδόν writing. Mr Moon, of the Brighton Blind Asylum, has slightly improved on Mr Frere's method. Dr Howe's typography is judged, however, to be superior to the British both in cheapness and in size. There are at present no less than five different systems of typography in use in Great Britain.

The following table shows the results of the six systems of printing for the blind used in the English language, taking the New Testament as a standard of comparison:—

Systems.	No. of Vols.	Size.	No. of Pages.	No. of Lines in a Page.	No. of Square Inches in a Page.	Price.
The New Testament:—						L. s. d.
Howe's.....	2	4to.	430	...	117	0 16 0
Alston's ...	4	„	623	42	90	2 0 0
Gall's......	8	„	...	28	70	2 0 0
Lucas's....	9	„	841	27	70	2 0 0
Frere's.....	8	Ob. 4to.	723	...	110	2 10 0
Moon's.....	9	„	...	25	110	4 10 0

(For an interesting account of the different systems of printing for the blind, see the *Reports of the Juries of the Exhibition* for 1851.)

Other Processes.

OTHER PROCESSES.

To the magnificent establishment of the imperial printing-office at Vienna we owe the introduction of several processes, which, though not founded on the use of type, belong to the art of printing. The description of these new arts is derived from the Reports of Jurors of the Exhibition of 1851.

Galvano-plastic Process.—The Austrian department contained some extraordinary prints of fossil fishes, which were produced by the following process:—By means of successive layers of gutta percha applied to the stone inclosing the petrified fish a mould is obtained, which being afterwards submitted to the action of a galvanic battery, is quickly covered with coatings of copper, forming a plate upon which all the marks of the fish are reproduced in relief, and which, when printed at the common press, gives a result upon the paper identical with the object itself.

Galvanography.—The artist covers a plate of silvered copper with several coats of a paint composed of any oxide,—such as that of iron, burnt terra sienna, or black-lead,—ground with linseed oil. The substance of these coats is thick or thin according to the intensity to be given to the lights or shades. The plate is then submitted to the action of the galvanic battery, from which another plate is obtained reproducing an intaglio copy, with all the unevenness of the original painting. This is an actual copperplate resembling an aquatint engraving. It may be touched up by the engraving-tool. This process has been improved upon by outlines etched in the usual manner, and the tones laid on with a roulette. A galvano-plastic copy of this sunk plate is obtained. On this second raised plate the artist completes his picture by means of chalks and Indian ink, and puts in the lights and shades; from this a second galvano-plastic copy is produced. This second copy or sunk plate, the third in the order of procedure, serves, after being touched up, for printing from in the copperplate press.

Galvanoglyphy.—Upon a plate of zinc coated with varnish a drawing is etched: then ink or varnish is rolled over. The ink adheres only to the parts it touches, every application when dry raising the coating and consequently deepening the etched lines,—a galvanic battery produces a plate in relief, which is printed at the common press.

Chemitypy.—A polished zinc plate is covered with an etching-ground. The etching is bitten in with diluted aquafortis. Remove the etching-ground, and carefully wash out the aquafortis. Heat the plate thus cleansed over a

Nature Printing.

spirit-lamp, after covering with filings of a fusible metal, until fusible metal has filled all the lines of the engraving. When cold, scrape down to level of zinc plate until none of the metal remains but what has entered into the engraving. Place compound plate in solution of muriatic acid; and as of the two metals one is positive the other negative, the zinc alone is eaten away by the acid, and the fusible metal which had filled the lines of the engraving is left in relief, and may be printed by the common press.

Paneiconography.—On a polished plate of zinc draw with lithographic crayon or ink, or transfer impressions from lithography, wood engraving, or copperplates. The thickness of the drawn lines is increased by repeated rollings or powdered resin. For relief-block, place plate in trough of very dilute sulphuric or hydrochloric acid. The acid eats away the unprotected parts of the plate, and leaves raised lines of the protected parts.

NATURE-PRINTING.

Mr Henry Bradbury, who has had a principal share in introducing this beautiful process into England, describes it as a method of producing impressions of plants and other natural objects, in a manner so truthful that only a close inspection reveals the fact of their being copies. So deeply sensible to the touch are the impressions, that it is difficult to persuade those who are unacquainted with the manipulation that they are the production of the printing-press. The process, in its application to the reproduction of botanical subjects, represents the size, form, and colour of the plant, and all its most minute details, even to the smallest fibres of the roots. The distinguishing feature of the process, compared with other modes of producing engraved surfaces for printing purposes, consists, firstly, in imprinting natural objects—such as plants, mosses, sea-weeds, feathers, and embroideries—into plates of metal, causing, as it were, the objects to engrave themselves by pressure; and, secondly, in being able to take such casts or copies of the impressed plates as can be printed from at the ordinary copperplate-press.

The art is by no means new in idea, many persons having attempted something analogous to the present process, and produced results which were imperfect, merely because science had not yet discovered an art necessary to its practical development. It is to the discovery of electrotyping that the existing art of nature-printing is due.

The progress of the art, and the persons to whose ingenuity the steps were severally due, are stated by Mr Bradbury thus:—

Professor Kniphof of Erfurt took impressions from leaves, &c., which had been coloured with lamp-black, printers' ink, &c., 1728–57.

Kyhl, a goldsmith of Copenhagen, took copies of natural objects in plates of metal between two steel rollers. These were not for the purposes of printing, but for reproduction of embossing and ornamentation in metal. 1833.

In 1851 Dr Ferguson Branson of Sheffield read a paper before the Society of Arts, in which he detailed some experiments in nature-printing. He had taken impressions from plants, &c., in gutta percha, for the purpose of having them printed. The experiment failed through the softness of the material. Dr Branson then bethought himself of the electrotype process; but appears to have found it too tedious and costly, and he abandoned the idea.

In 1849 Professor Leydolt of Vienna availed himself of the facilities afforded by the imperial printing-office to carry out experiments in the representation of flat objects of mineralogy,—such as agates, fossils, and petrifactions,—and obtained great results. Soon after, Haidinger and Abbate suggested, the former the reproduction of plants, &c., and the latter the representation by this means of different sorts of ornamental woods on woven fabrics, paper, and plain wood; and lastly, Andrew Worring, of the imperial printing-office, Vienna, perfected the application of these processes to printing, 1853.

These circumstances are dwelt upon at some length, because nature-printing is yet in its infancy, and appears capable of development to a degree at which it will be an impressorial art of greater importance than any which has been invented since the art of printing itself. Worring's services were so highly estimated that the emperor rewarded him with a munificent gift, and with the Order of Merit.

The plant, perfectly dry, or any other suitable subject, is placed on a plate of fine rolled lead, the surface of which has been polished by planing. The plate and subject are then passed between rollers, by the pressure of which the subject is forced into the surface of the lead. The leaden plate is then subjected to a moderate heat, by the action of which the subject is loosened from its bed and easily removed. This mould is then subjected to the galvanoplastic process, the second cast being a perfect fac-simile of the leaden mould. When the subject to be printed is of one colour only, that pigment is rubbed in, and any superfluity removed; but when it is of two or more colours, the process is simple, but, it is believed, perfectly novel in any process of printing heretofore practised. In the case, for instance, of flowering plants, having stems, roots, leaves, and flowers, the plan adopted in the inking of the plate is to apply the darkest colour, which generally happens to be that of the roots, first; the superfluous colour is cleaned off; the next darkest colour, such, perhaps, as that of the stems, is then applied, the superfluous colour of which is also cleaned off; this mode is continued until every part of the plant in the copperplate has received the right tint. In this state, before the plate is printed, the colour in the different parts of the copper looks as if the plant were embedded in the metal. The plate thus charged, with the paper laid over it, is placed upon a copperplate-press, the upper roller of which is covered with five or six layers of blanket of compact fine texture. The effect of the pressure is, that all the colours are printed by one impression; for when the paper is removed the plant is seen quite perfect, highly embossed, with the roots, stems, and other parts, each of its proper tint.

The great national work which the Austrian establishment has produced as the exemplar of the new art is truly imperial. The *Physiotypia Plantarum Austriacarum* consists of 5 volumes large folio, containing 500 plates (about 600 plants), with a quarto volume of plates and text. The first production of the English press, though it will bear no comparison in extent with the imperial magnificence of the Austrian work, fully equals it in beauty of execution. It is *The Ferns of Great Britain and Ireland*, by Thomas Moore, edited by Dr Lindley, imperial folio, with 51 plates. It is printed by Mr Bradbury. (See notices of meetings of the Royal Institution of Great Britain, part v., 1855; and the printed Lecture delivered at the same Institution, May 11, 1855.)

Printing in Colours.

PRINTING IN COLOURS.

One of the most beautiful aids to typography, the art of printing in colours, has been unduly neglected in this country; at least as far as relates to the embellishing works of ordinary excellence with vignettes, capitals, tail-pieces, and other devices of fancy, in beautiful tints, in the manner of the early typographers. It is true that some very beautiful works, illustrated with remarkable richness of design and colour, have been produced; but these have been executed rather as examples of the beautiful in art than as books,—the work of the artist has been the principal object, and the work of the author the occasion and vehicle.

In other works, chiefly ecclesiastical, the object has been to reproduce in *fac-simile* the rich illuminations of the monkish scribes. But as regards the average printing—the literature of the day—the art of printing in colours has been very much neglected. This may very easily be accounted for. To print in two colours occupies more than twice the time necessary to print in one; and it also requires more skill and ingenuity. These unfortunately must be paid for; and this pecuniary consideration is sufficient to banish from our pages this lovely art. So did not our forefathers; *they* took pride in choosing the most tasteful designs, the most harmonious colours, to illuminate their productions, and beguile the reader into study by the illusive charms of gold, and blue, and crimson. Fortunately, either time was of little value, or the exclusive possession of the market enabled them to demand remunerating prices for the time thus well bestowed; but in the bustle and competition of our more mercantile days, time is money, and blue and gold, scarlet and green, give way to the equally useful but infinitely less beautiful uniformity of unredeemed black. To a country printer, however, some knowledge of colour-printing would be of advantage, because, as his founts of type are more limited, he can create unlimited variety by a judicious use of colours in job-work: moreover, as he has usually much more time upon his hands, his ingenuity would have ample scope for the production of small works of *vertù*, in a taste which cannot be indulged by the denizens of a busy metropolis.

Except in the execution of works of a very high order, and the imitation of intricate and delicate patterns, printing in colours requires no addition to the ordinary accomplishment of printing, other than considerable ingenuity and a little practice in preparing the colours. The latter may, it is true, be purchased of the ink-maker, prepared for use; but the charge for them is enormous, and they require constant replacement, whilst it is not possible to have on hand every variety of tint. By the purchase of the most simple materials from the oil-shop, the ingenious printer has at his hand every colour that fancy can require, at the most moderate cost, without waste or delay. The appliances are few and cheap: a muller, a marble slab, and a palette-knife; the materials, a can of printers' varnish, to be purchased of the ink-maker, which will keep any length of time, and the raw colours hereafter given, which may be purchased from time to time; care, however, being taken that they are of the best quality, or they will fade and turn rusty in a short time, and be a deformity instead of an ornament to the work.

Useful tints of *red* may be prepared of orange lead, vermilion, burnt sienna, Venetian red, Indian red, and lake. Vermilion is the most brilliant of these reds; but its beauty depends very much upon the particular parcel used. The pale vermilion is best for a bright tint, as the dark, when mixed with the varnish, produces a dull red. Orange lead and vermilion ground together produce a very bright tint, which is more permanent than vermilion alone.

Yellows are prepared with yellow ochre, gamboge, and chromate of lead. Of these, the brightest is the chrome; yellow ochre, when mixed with the varnish, produces a very dull tint.

Blues are made from indigo, Prussian blue, and Antwerp blue. Of these, indigo is exceedingly dark, and not very easily lightened. Prussian blue is a very useful colour; Antwerp blue is very light.

Greens may be produced from a mixture of any of the blues and yellows, as gamboge and Prussian blue, chromate of lead and Prussian blue. These may be mixed in any proportions until the required tint is produced; but it must be remembered that the varnish has a considerable yellow tinge, and will produce a decided effect upon the mixture. With a slight portion of Antwerp blue it will, without the mixture of any of the yellows, produce a decidedly greenish tinge.

Purples of any degree of richness are made by judiciously mixing reds and blues.

Sæpia produces a nice brown tint, burnt umber a very hot brown, raw umber a much lighter brown, bistre a brighter still. Neutral tints may be obtained by mixing Prussian blue, lake, and gamboge. In fact, every pigment that painters use can also be used in printing, avoiding, as much as possible, all heavy colours. In truth, if the printer is desirous of imitating any particular colour, or of producing any particular tint, he cannot do better than consult the nearest artist in oil or water colours (oil in preference), or in default of that, the neighbouring house-painter.

The necessary colours having been procured, the method of preparing them is very simple. Each must first be well ground by the muller upon the slab, even although they may have been purchased well powdered. The colour should then be well mixed with the palette-knife with the varnish, until the pigment has attained the required consistency, which will vary with the quality of the work to be executed; for if it be a posting-bill or coarse job, the ink should be very thin, and consequently a much larger proportion of varnish should be used. If, however, the work be a wood-cut, or in small type, the pigment should be made as thick as possible. If the colour required be a compound, the predominant tint should be first mixed with the varnish, and the lighter tint added in small quantities, until the exact shade required be produced. Thus, if the colour be a dark green, the blue should be mixed up first, and the yellow added; but if it be a very light green, then the yellow should be first applied, and the blue added. If the tint desired be exceedingly light, it will be found that the quantity of raw material to be employed will not make the mixture sufficiently thick to be applied to the type or wood-block: in this case whitening is added to thin colours, and dry white lead to the heavier, in considerable quantities, which must be adjusted in the course of mixing. To insure thorough combination, the mixture should be scraped into a corner of the slab, and a very small portion of it spread with the palette-knife, and well ground with the muller until no specks or lumps appear, then scraped up and placed in another corner. This should especially be done when white lead is used, as it will be found that every little lump when crushed will produce a white streak upon the slab. If this be not carefully done, independently of its tendency to clog the type, it will very materially alter the tint. When the pigment seems sufficiently mixed, it is better to bray it out with the muller instead of the usual brayer, and grind again each particular portion immediately before it is used. Colours may be worked either with a ball or a roller. If the job be large and coarse, and the ink consequently thin, the roller will answer every purpose; but if it be small, and requiring much nicety in the manipulation, decidedly with a ball; but in either case the ink should be well distributed, and the form well beaten or rolled. When two or more colours are employed, they must be worked at as many different times. In this case extreme nicety in the register and justification is required, in order that every colour may fall in its just place, without overlaying any other tint employed in the print. This would be a great dis-sight in any case, but most especially where the combination of colours would produce a third; as, for instance, if any part of a blue line should unfortunately fall upon a yellow, a green outline would be the result. The simplest way to guard against this is to have the wood-blocks all cut to precisely the same size, with the print in the proper place upon each; when, therefore, the first colour has been worked, the form is unlocked, the block taken out, and the second block inserted; it then falls at once into

Printing in Colours.

its proper position. If the form consist of type, each line should be carefully composed in its proper body; that is, if three colours be employed for as many different lines in *pica, small pica*, and *long primer*, the one to be first worked should be composed in pica *letters*, the other lines in small pica and long primer *quadrats*. When the second line is to be worked, its quadrats should be taken out and letters inserted, while the type of the first line should be removed and quadrats substituted; and so of the third line. The points on the tympan must never be moved. It is clear, therefore, that if the paper be placed upon the same point-holes as before, and if the form has never been moved, the new line cannot fail to fall into its proper place. The illustrative Plate III. has been worked upon this plan; the black, being the largest body, was first printed, as it afforded the best guide for subsequent working. The blue was next worked, because it was much easier to adjust it to the black, than to adjust the red so exactly that the blue should precisely surround it and yet not infringe upon or retreat from the black, while there would be no difficulty in making the other red portions fall in their proper places. In these cases the paper must never be suffered to dry; indeed the sooner each colour succeeds the other the better. If it be covered with a wet blanket, and the edges well sprinkled, the danger will be little; but if it should dry and shrink in the slightest degree, it will be impossible to obtain register. For printing *red-letter days* in almanacs and the rubrics in prayer-books (an almost extinct practice), an especial type is used called rubrical; it is cast about an m higher than ordinary type. The black is first worked, quadrats having been inserted in the places of the red letter, which are subsequently withdrawn, and the rubrical type inserted. But as, in so small an insertion in so large a body this process does not attain any very good register, and is expensive withal, the red-letter days have been abandoned, and some other distinguishing type (generally old English or black) has been substituted, which sufficiently indicates the day. It would not be possible here to give sufficient instructions to enable a printer to execute landscapes, portraits, and other delicate subjects, in various colours and shades. The difference between this and other colour-printing consists mainly in the superior individual skill and ingenuity of the artist, the excellence and truth of his engravings, and the superiority of his appliances. In truth, before the printer can produce any great effect, he must be excellently qualified as a painter, which it is not the province of an article on printing to teach. It will be sufficient to state that the lighter and more extensive tints, and especially those in which transparent colours are used, are worked first; that the colour is gradually deepened by successive blocks until the required effects are produced; and that the outline is printed last, which has the effect of giving sharpness and finish to the design.

The curious reader is referred to Mr Savage's beautiful book on Decorative Printing, and to the many admirable productions of Mr Baxter and Mr Vizetelly. Nor should the accurate work and beautiful colours of Mr Delarue's playing-cards be passed over without notice. To Mr Delarue, indeed, the revival of colour-printing as a practical art is greatly due.

The lottery system and the stamp duties gave extensive employment to the colour-printer, and also gave occasion to a process which is denominated "compound plate-printing." The effects are produced by an ingenious system of mechanism, by which several plates are made to separate for the purpose of receiving the colours, and to combine with perfect accuracy, for the purpose of transferring these colours to the paper by a single impression. This process is in daily use at the stamp and excise offices, and the most familiar examples are to be seen in the intricate patterns printed on the labels of reams of paper, or those of patent medicines. The printing is effected by the cylinder printing-machine with the greatest rapidity.

There is no difficulty in printing in gold; it is within the power of any typographer. The type is composed and made ready at press in the usual manner. Take the best printer's varnish, grind it to a thick consistency with burnt sienna or brown umber; reduce this with gold-size, the same as that used by gilders and japanners. The first admixture is necessary because it has been found that the number will not combine with the size. The type is then rolled with this compound in the same manner that ordinary ink is applied, and the impression is taken upon the paper. Leaf-gold is then laid over it with a piece of cotton wool, and pressed lightly upon it. When the varnish has had time to set, a piece of cotton-wool is rubbed steadily over the part printed, and the superfluous leaf is thereby removed, leaving the gold adhering to the varnish. The print should then be passed between steel rollers, or hot-pressed,—care being taken in the latter process that the plates be not too hot, or a dull drossy surface will be produced. The sharpness of the print will vary with the judgment of the printer in the quantity of sizing applied to the type; for if the press-work be bad, the print will be bad also. For inferior gold-printing bronze-powder is extensively used. For this the varnish is made very much thicker than for gold: the method of printing is the same. After the impression has been given, the powder is brushed over the print, and adheres thereto, whilst the superfluity is easily removed. In printing the golden "Coronation Sun" with this powder, a very distressing disease arose,—the hair became perfectly green, and the men were very seriously affected; great care should therefore be taken that particles of the powder be not allowed to fly about the room. Dutch gold cannot be used as a substitute for gold-leaf. When all these appliances cannot readily be obtained, very fair gold-printing may be produced by the following process:—Let the surface of the type be heated by any convenient means—as by laying upon it for a space a heated metal plate—and then cover it carefully with leaf-gold by a ball of cotton-wool. Having carefully sifted dry white-of-egg or resin, finely pulverized, over the surface of the paper, place it on the tympan, and bring it gently down upon the type. Dwell upon the pull. The leaf-gold will be found perfectly adherent to the impression on the paper, and the superfluous part may be brushed off. The sheet, after drying, should then be hot-pressed. Some observation is required to ascertain the proper heat to be given to the type: if it be insufficient, the gold transfer will be imperfect and the tint light; if too great (of which there should be no danger) the colour will be dull.

Bank-Note Printing.

BANK-NOTE PRINTING.

The Bank of England notes were formerly printed from steel-plates; but in 1853 the Bank adopted the surface or letterpress mode of printing. The plates are produced by the electrotype process. An original is first engraved in metal *in relief*. This original is subjected to the galvano-plastic process, by which a matrix is obtained, and from this matrix a second cast is obtained in relief, a perfect *fac-simile* of the original engraved plate. From this plate the bank-notes are printed. The metal of which these plates are formed is exceedingly hard, frequently yielding nearly one million impressions without being worn out. The original engraving is never used for printing, but only for the production of matrices; consequently it always remains unimpaired, and thus perfect identity is maintained in the appearance of the notes.

Printing-Presses.

The notes are printed at platten-machines possessing great advantages over the ordinary printing-machines, more particularly in the distribution of the ink. Three machines are employed, two of which were manufactured by Messrs Napier & Sons, and the other by Messrs Hopkinson & Cope. A *tell-tale*, or register, is attached to each machine, which marks the number of impressions. These registers are set by a clerk before the printing commences, and are checked by him at the close of the day, when the printer must account for (either in bank-notes or "spoils"), the number of impressions registered by the dial. The notes are printed upon dry paper, a process which has been very greatly accelerated by the recent improvements introduced into the ink by Mr Winstone, who manufactures for the bank.

The numbers and dates of the bank-notes are added in an after-printing. This is effected at Messrs Napier & Sons' cylinder machines: a very ingenious mechanism being attached to these machines which makes it impossible to commit any fraud by printing two notes of the same number. The apparatus consists of a series of brass discs, of which the rim is divided by channels into projecting compartments, each containing a figure. The numbers 1 to 9 having been printed in the course of the revolution of the first disc, the second disc then presents the figure 1, which, by combining with the 0 of the first disc, the number 10 is formed. The second disc now remains stationary until, in the course of the revolution of the first disc, the numbers 1 to 19 have been printed, when it presents the figure 2, and does not again move until another revolution of the first disc completes the numbers 20 to 29. Thus the two discs proceed until 99 notes have been numbered, when the third disc comes into operation, and with the first two, produces 100, consequently the first disc performs one hundred revolutions to ten of the second and one of the third. The notes may be numbered indefinitely by this process, without the possibility of error, the machine, meanwhile, being its own check.

PRINTING-PRESSES.

In the description of the Stanhope press it has been stated that many other presses upon different principles have been since invented; most of these, however, contain some application of the Stanhope power. The most powerful and durable, but the most expensive, is the Columbian or Clymer Press (fig. 6). The power in this press is acquired by an extremely massive lever, moving on a pivot-bolt in the top of the near staple, and passing over the press to the further staple, at which end the power is applied, through the Stanhope coupling-bar, by a bar-handle working from the near side. The platten is attached to the centre of the lever by a square bar of iron, and its vertical descent is preserved by two projecting guides, one from each cheek; it is raised from the form, and the iron bar carried back, by two levers,—the one attached to and above the head, weighted with an eagle; and the other behind the press, attached to the arm to which the coupling-bar is fixed, and having a weight at the end. The great power of this press adapts it to the working of large and solid forms; but it is heavy and slow. It is, it should be remarked, too high for small premises.

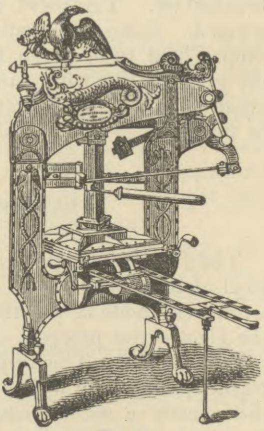

Fig. 6.

Printing-Machines.

The Albion Press (Fig. 7), manufactured by Hopkinson and Cope, is much esteemed for its exceeding lightness: it runs very easily, the pull is short, the power great, and the means whereby it is attained so simple, that there is little fear of the press getting out of order. It is very easily taken down for cleaning, and put up again. The power is gained by causing an inclined piece of steel to become perpendicular; in so doing the platten is forced down, and the impression takes place at the moment the piece of steel is brought into a vertical position. On the return of the bar, the platten is raised by a spiral spring fixed on the head of the press.

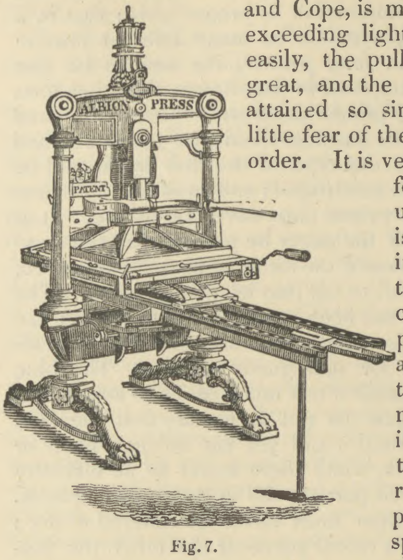

Fig. 7.

Cope and Sherwin's Imperial is another very excellent press, upon principles which do not greatly differ from the Albion.

In Harrild's Press the power is obtained by the straightening a knuckle or elbow-joint, in precisely the same manner as the bent arm is straightened.

PRINTING-MACHINES.

As long as the thirst for literature was confined to books and a few periodicals of limited sale and size, the ordinary printing-presses sufficed to supply the demand; nor was it discovered that any further speed was requisite, until the increased facility of conveyance, and the important events at the close of the last century, created a demand for news which the utmost exertions of the printers were unable to supply; for the attempt to increase the speed by the composition of two distinct forms of type would avail little, so long as the presses could turn out only 250 or 300 impressions each per hour. Accordingly for this branch of the art were the first machines projected. Many schemes were proposed for accelerating the movements of the press; but the first attempts at anything like the machine afterwards introduced were made by William Nicholson, a gentleman connected with periodical literature, who took out a patent about 1790 for a printing-machine, of which the chief points were the following:—The type being rubbed or scraped narrower towards the bottom, was to be fixed upon a cylinder, in order, as it were, to radiate from the centre of it. This cylinder, with its type, was to revolve in gear with another cylinder covered with soft leather (the impression-cylinder); and the type received its ink from another cylinder, to which inking apparatus was applied. The paper was impressed by passing between the type and impression cylinders. Most of these plans were, when modified, adopted by after-constructors. This machine was never brought into use.

König, an ingenious German, was the next who undertook to construct a machine; and having made considerable advance in his plans, obtained a contract with Mr Walters, the proprietor of *The Times* newspaper, for manufacturing two for that journal. His machine was successful, and the number for the 28th November 1814 was worked by it at the rate of 1100 impressions per hour. In this Nicholson's plan was so far altered, that the ordinary type was used and laid upon a flat surface, and the impression was given by the form passing under a cylinder of great size. König afterwards invented a machine in which the sheet was printed on both sides before it left the machine; but his arrangements for the equal distribution of the ink were so complicated and clumsy (consisting of not less than forty wheels), and the works of every part of the machine so intricate, that it never came into practical use.

The first really useful machine was constructed by Messrs Applegath and Cowper, being an extensive modification of that of König; its principal improvement consisting in the application of two drums between the impression-cylinders, one of which reverses the sheet, and the other secures the register, by retaining it, after the impression of the first form, just so long that it may pass on to the second cylinder in exact time to be impressed thereby upon the second form; and of the distribution of the ink upon a plane surface, instead of by a number of rollers, by which König's complicated machinery was got rid of. These machines, with numerous modifications, according to the plans of different makers, are now in general use.

For newspapers, machines are generally made to work but one side at a time. It is manifest that a machine will work a much greater number (more than double) of one form than of two, and that the machinery will be lighter and less expensive, and of course require less motive power. One form, therefore, of a newspaper, containing advertisements and the less important matter, is worked at leisure; and the second form, containing the leading article, important news, and other matter of consequence, is reserved until the last moment, and is then thrown off with immense rapidity. For the usual description of book-work, machines (perfecting-machines) are constructed to work both forms at a time. In these, perfect register, and the exact and even distribution of the ink, are of the greatest consequence, and such immense rapidity is not necessary. These machines, therefore, differ very much in construction, though not in principle, from those used for newspapers.

The subjoined engraving (fig. 8) is a representation of Middleton's admirable perfecting-machine, which is the same in principle as Applegath and Cowper's, but with some improvements. An explanation of this machine will enable the reader to comprehend the construction of all the cylinder machines, the same principle pervading all of them. Upon friction-rollers placed within the frame which supports the whole apparatus, traverses a carriage which conveys the two forms of type, and attached to both ends of which are tables for the distribution of the ink. A reciprocating motion is given to this carriage by means of a pinion, which works alternately upon the upper and under surface of a rack. In gear with this carriage, and, supposing the paper to be omitted, in immediate contact with the type, revolve two cylinders of large dimensions, covered with blankets, by which the impression is given; these cylinders are separated by two drums, but are kept in uniform and steady motion by two large wheels (seen at the back of the engraving), the teeth of which work within each other. The ink is distributed over the forms by an apparatus attached to each end of the frame, consisting of a trough which contains the ink, in contact with the edge of which, or very nearly so, a metal roller called the *ductor* is made to revolve slowly by means of a catgut, which passes over a pulley attached to the axis of the impression-cylinder. A composition-roller is made to rise into contact with the ductor, and receive a portion of ink, with which it descends, and communicates it to the inking-table as that passes underneath it at the extremity of the traverse. Two composition-rollers are placed somewhat diagonally across the frame, and their spindles being of extra length, as the table passes under them they are caused to revolve and also to travel slightly across it, thus evenly distributing the ink all over the surface of the inking-table, the cross motion removing any accidental accumulation of ink. The table now traverses under four other composition-rollers, supplying them with an even quantity of ink, which they in turn distribute over the type as it passes under them in going and returning, the form being thus rolled no less than eight times. These rollers are merely dropped into notches in the frame, their own weight sufficing to retain them in their places, and to bear sufficiently hard upon the type to impart the necessary quantity of ink. For the purpose of carrying the paper round the different cylinders there are two distinct series of endless tapes, one of which, coming in contact with the left surface of a small roller,[1] passes from thence to the right surface of the first cylinder, and underneath it; thence *over* the first and *under* the second drum, which reverses the sheet, and has an apparatus attached to it for making register; thence to the left surface of and under

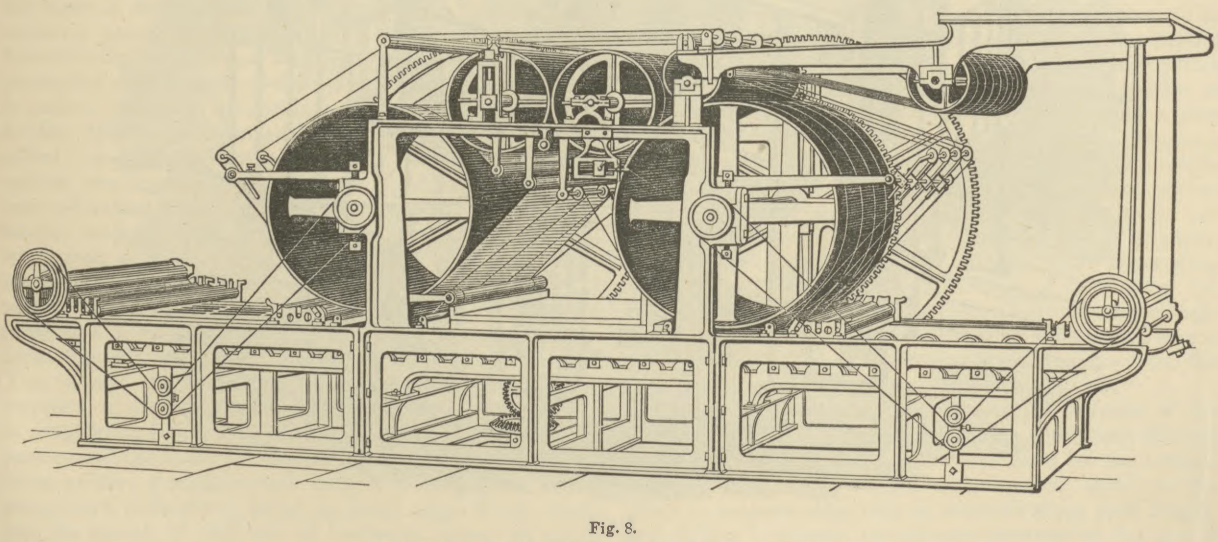

Fig. 8.

Applegath and Cowper's Perfecting Machine, by Middleton.

---

[1] The description commences with that portion of the machine where the paper first enters the machinery, for *endless* tapes can of course have no *beginning*; the words *first*, *second*, and *third*, &c., must therefore be understood to refer to the position as respects the *right hand* of the reader.

the second cylinder; from this it passes to the right, until it arrives at the roller first mentioned. The course of the second series of tapes is different; for, following the course of the first series, and in contact with it (supposing the paper withdrawn) until it has passed with it under the second cylinder, it then takes a different direction, and, turning to the left, passes over the machine until it arrives at the roller from which we have commenced the description. Both series of tapes are kept tightly stretched by means of various small rollers revolving in different parts of their course. The paper being laid upon other tapes from a table at the right of the machine, is moved forward until it comes in contact with the endless tapes, and being received between them, it is passed under the first cylinder, and the first side is then printed; thence passing over and under the drums on to the second cylinder, it receives the impression upon the other side; thence it passes onward to the point where the tapes take different directions, when it is shot out printed on both sides, upon a board between the cylinders and under the drums. The whole machine is put in motion by means of a strap which passes over a wheel under the frame, and *may* be worked by the power of men, but is mostly worked by steam. It is capable of doing very fair work at the rate of from 2000 to 2400 impressions, or from 1000 to 1200 perfect sheets per hour: it requires only two boys, one to lay on and the other to take off the sheets.

The machine constructed by Messrs Applegath and Cowper in 1827 for *The Times*, two of which are still used for printing the supplements and advertising pages, differ considerably from that just described. It has four impression-cylinders, which are so arranged that two are in contact with the type as the table passes to the right, and two as it passes to the left. As this machine prints the paper on one side only, the systems of tapes are single. It will print from 4000 to 5000 impressions per hour.

One of the principal impediments to great speed in this form of printing-machines is the necessity for a reciprocating motion in the type, table, and inking-table,—a great weight, the *vis motus* of which has to be neutralized, and then the *vis inertiæ* overcome, at each end of the traverse. This not only occasions a great waste of motive power, but also causes breakages and serious accidents. Mr Applegath, finding these and other difficulties insuperable, abandoned the principle of placing the type on a plane table and the reciprocating motion, and constructed a machine in which the type is placed on the surface of a cylinder of large dimensions, which revolves on a vertical axis, with a continuous rotatory motion. *The Times* has the credit of being first in adopting this great improvement in newspaper printing.

The following is a careful description of this vast and complicated piece of machinery:—

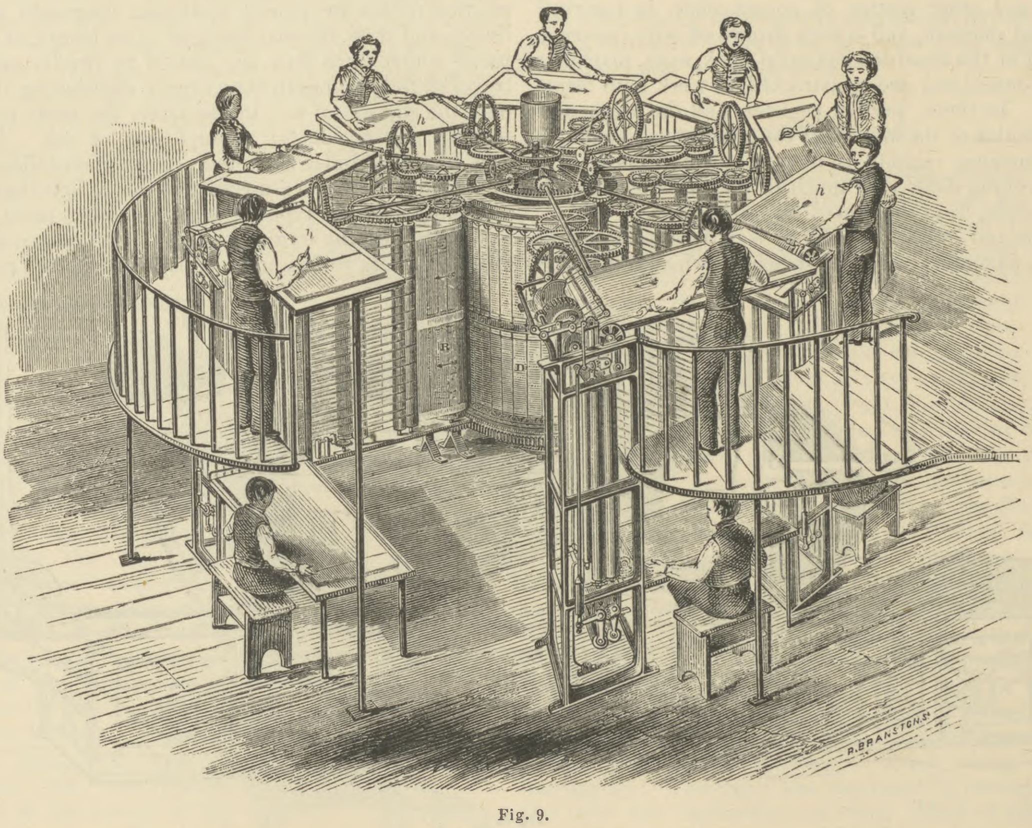

Fig. 9.
Applegath's Vertical Machine.

In the centre of the machine (Fig. 9) is a vertical cylinder or drum, 5 feet 4 inches in diameter. In contact with it, and revolving each on its own vertical axis, are eight impression cylinders, 13 inches in diameter, each of which has a set of inking-rollers working in advance of it. The cylinders move with the same velocity as the surface of the drum. The columns of type are placed in a kind of iron galley, or *turtle*, curved to fit the surface of the drum. The outer surface of these galleys is not formed into a segment of a circle, but into facets, each the width of a column; the wedge-shaped interval, which is left between the top and bottom of the types of every two adjoining columns, is compensated by column-rules, made thicker at the top than at the bottom in the same proportion. The middle column-rule is fixed. The columns are locked-up in the galleys by means of screws, and the column-rules press the types together like key-stones in an arch. The fixed rule in the centre prevents the types from rising. The galleys are then screwed on to the drum, the columns vertical. The outer face of the forms is now, it must be remembered, a series of facets, sides as it were of a polygon; the surfaces of the impression-cylinders are made to conform to these facets, with sufficient accuracy, by paper overlays. When stereotype plates are used, they are cast by Dellagana's process, in accurate segments of a circle, and the overlaying is unnecessary. The forms of types do not, of course, occupy the whole circumference of the central drum: a large part of the remainder is made the inking-table. The ink-box, which is also vertical, supplies ink to a ductor-roller, which works between two straight edges. As the drum revolves, a portion of ink is taken from the ductor by two vibrating rollers, and distributed on to the inking-table. The inking-table precedes the type-forms, and as it passes the inking-rollers attached to each impression-cylinder come into contact with it, and receive ink from its surface. The type-forms, following next, come into contact with these inking-rollers, and take from them the ink they have just received. The inking-table passes under the impression-cylinders without touching them; but the type is brought into contact with the paper upon them, and the impression is given. Therefore, at every revolution of the drum, the type is inked eight times, comes into contact with eight impression-cylinders, and prints eight sheets of paper.

It is most difficult to convey, by any verbal description, the singularly ingenious mechanism by which the sheets of paper are conveyed to and round the impression-cylinders. It must be remembered that the sheets are necessarily laid on the feeding-table *horizontally*, and that they pass round the cylinder *vertically*. The task will be rendered somewhat simpler by reminding the reader that each impression-cylinder is a complete machine within itself, acting with the drum, but independent of the other cylinders; and that, as each has its own system of inking-rollers, so each has its own system of feeding-drums and tapes. By looking closely at the apparatus on the right front of the drawing, he may be able to follow the description. The white paper is laid on the feeding-table at the top; each sheet is placed by the layer-on to the centre of a feeding-drum. At the right moment, the sheet is advanced by finger-rollers until its forward edge is brought between two small rollers, each connected with a series of endless tapes, between which it is passed vertically downwards. At the right moment its further progress is arrested by two vertical slips of wood called "stoppers," which start forward and press the sheet against two fixed stoppers; and, at the same moment, the two rollers and their tapes separate, and leave the sheet extended vertically between the two pairs of stoppers. Observe that, up to this moment, the travel of the sheet has been vertically downwards, and that its plane surface is part of a radius from the axis of the central drum. The problem now to be solved is, to give it a horizontal movement towards the centre, preserving its vertical position. The instant the sheet is arrested vertically between the stoppers, its top edge is caught by two pairs of small finger or suspending rollers; at the same instant the stoppers separate, and the sheet is suspended for a moment between these rollers; a slight inward motion is then given to the suspenders, sufficient to bring the inner edge of the sheet into the mouth of two sets of horizontal tapes, by which it is carried round the impression-cylinder and printed. As the sheet, after being printed, issues from the horizontal tapes, it is delivered to other sets, by which it is conveyed outwards, under the laying-on board; arrived at the proper point, it is again caught at the top edge between suspending rollers, the tapes separate, and it hangs for a moment; when the taker-off, who sits below the layer-on, releases it by a slight jerk, and lays it on his board.

No description can give any adequate idea of the scene presented by one of these machines in full work,—the maze of wheels and rollers, the intricate lines of swift-moving tapes, the flight of sheets, and the din of machinery. The central drum moves at the rate of 6 feet per second, or one revolution in 3 seconds; the impression-cylinders make 5 revolutions in the same time. The layer-on delivers 2 sheets every 5 seconds, consequently, 16 sheets are printed in that brief space. The diameter of an eight-feeder, including the galleries for the layers-on, is 25 feet. *The Times* employs two of these eight-cylinder machines, each of which averages 12,000 impressions per hour; and one nine-cylinder, which prints 16,000.

These vast machines, however, are only useful when the necessity of working a very large number with the utmost rapidity overrides all consideration of cost and space. An excellent machine, in which considerable speed is obtained with comparative economy of expense and room, the invention of Messrs Hoe of New York, has been lately used for newspapers and periodicals of long numbers. In principle, it does not differ from Applegath's vertical, inasmuch as that the type is fixed upon a central cylinder or drum, which has a continuous rotatory motion, in contact with impression-cylinders set around it. The chief difference is, that the drum and impression-cylinders are not vertical, but horizontal. The machines are manufactured of different sizes, according to the number of impression-cylinders required. Those more generally made have six cylinders, some have eight, and *The Times* has recently constructed one with ten. This last machine is calculated to produce 20,000 impressions per hour. The following is a representation of a six-cylinder machine (fig. 10):—

A horizontal central cylinder is mounted on a shaft with appropriate bearings, and around it, arrayed at proper distances, are six horizontal impression-cylinders. The moveable types or stereo-casts are secured on a portion of the central cylinder, about a quarter of its circumference, and compensated by a balance-weight on the opposite side; the remainder of the cylinder is used as the distributing-table for the ink. This portion of the cylinder is lower than the face of the type, in order that it may pass under the impression-cylinders without being touched by them. The ink is contained in an ink-box placed beneath the central cylinder, and supplies the ink to the ductor-roller, from which it is transferred by a vibrating distributing-roller to the distributing-table. The ductor-roller receives a slow and continuous rotary motion, so that it always presents a uniform line of ink to the vibrating roller. The machine being put in motion, the form of type on the central cylinder is brought into contact with each of the six impression-cylinders in succession; and six sheets of paper, which have been introduced, one to each impression-cylinder, are printed in one revolution of the central cylinder. For each impression-cylinder there are two inking-rollers, which roll over the distributing surface and take a supply of ink; at the proper time they rise, pass over the type, and then fall on to the distributing surface.

Each page is locked up upon a detached segment of the large cylinder called a "turtle," which constitutes the bed and chase. The column-rules, like those for the vertical machine, are wedge-shaped, and are held down to the turtle by tongues projecting at intervals along their length, and sliding in rebated grooves cut crosswise in the face of the turtle, the space in the grooves between the column-rules being filled with sliding blocks of metal, accurately fitted, the outer surface level with the surface of the turtle, the ends next the column-rules being cut away underneath to receive a projection in the sides of the tongues. The head and cross rules are segments of a circle of the same curvature as the turtle. The types are secured by screws and wedges.

Six persons, one to each impression-cylinder, are required to supply the paper,—three on each side of the machine. The paper is conveyed from the laying-on board to the impression-cylinders by gripers. The sheets when printed are carried by tapes to six self-acting fly-frames, which lay them regularly in piles.

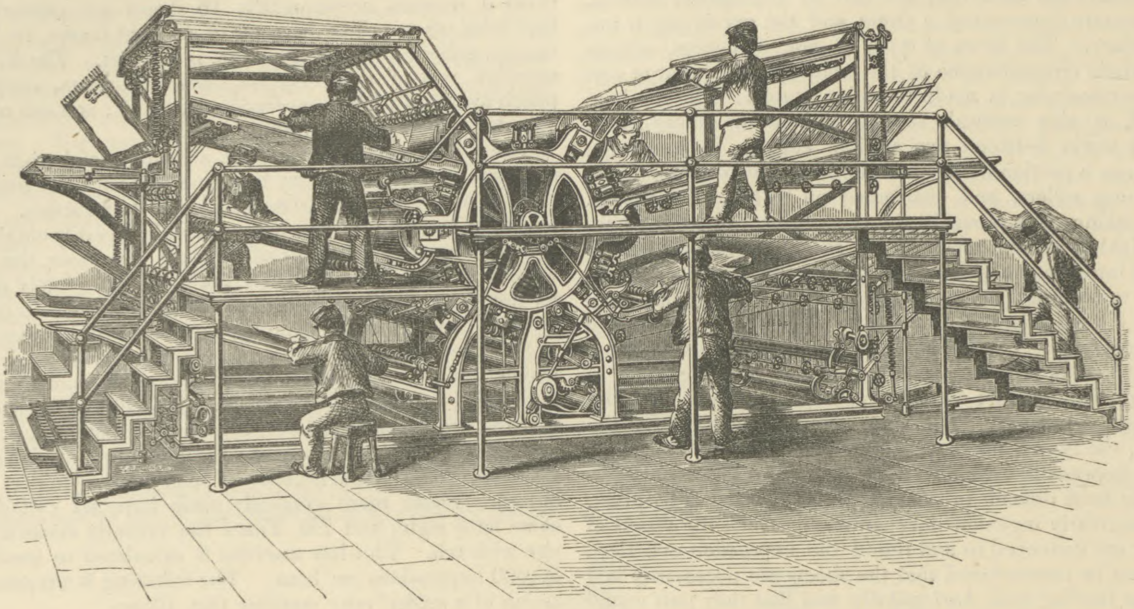

Fig. 10.
Hoe's Printing-Machine.

Another American, M. S. Beach, has improved upon Hoe's machine, by converting it into a perfecting-machine. His improvement consists in placing the second form upon the central type-drum, superseding the necessity for the balance-weight: the sheet, after being printed on one side, is immediately drawn back and printed on the other side from the second form, without checking or changing the uniform revolution of the cylinder; and thus the work done by it is doubled. The diameter of the type-drum in this machine, which is calculated for 8 impression-cylinders, is only 4 feet; the type has therefore to travel a less distance in one revolution of the drum; and the consequence is, that in travelling the same distance in this machine, and at the same speed, 22,000 *double* impressions would be produced in an hour. This account is taken from the *New York Sun*, the machine itself not having as yet found its way across the Atlantic.

A horizontal cylinder-machine, on the same system as Hoe's, made by Middleton, capable of printing 20,000 impressions per hour, is now used for printing *The Morning Herald*. The type is secured on the central cylinder, 2½ feet in diameter, in the same way as in *The Times* vertical machine; the ink is supplied from a ductor below the type-cylinder, and distributed upon an inking-table attached to the type-cylinder, to which a slight lateral motion is communicated by two straps, one on each side of the machine. There are five impression-cylinders at equal distances round the central cylinder, to which the paper is supplied from ten feeders, on the same principle as in the other horizontal machines, four on one end of the machine and six on the other; the printed sheets are delivered on to five taking-off boards, one to each two feeders, and received by five lads. The machine is 26½ feet long, 5 feet wide, and 17½ high.

The machines of Mr Napier, intended for book-work, are in good repute. They have the advantage of being easily worked by two men, thus rendering steam-power unnecessary. They stand in a very small compass, and do beautiful work. As far as regards motion and impression, they do not greatly vary from the cylinder machine already described; but in the method of conveying the paper, obtaining register, and inking, they are altogether different. The paper is laid to a certain gauge, when, in the revolution of the cylinder, gripers are made to compress the edge of the paper upon it, very much in the manner in which the fore-finger closes on the thumb. It is by these means conveyed with it during one revolution, in the course of which it is printed on one side. At the commencement of the second revolution these gripers open at the precise moment, when the gripers attached to the second cylinder close, and thus convey the sheet over the second form. Tapes pass under the second cylinder, *between* the blanket and the paper, and over a pulley upon a bar, by the mere friction of which the sheet is thrown out upon a board. These gripers are made to act with such perfect certainty that the best possible register is obtained. The inking apparatus consists of a trough with a ductor and vibrating roller, which communicates the ink to composition-rollers, by the revolution of which in contact with each other the ink is perfectly distributed, and from these to the type. A cross motion is communicated to the distributing-roller by means of a worm in the elongated spindle. As but one impression is given during the traverse of the table in each direction, the cylinder which does not at the moment hold the paper would be in contact with the type, had not Mr Napier added a beautiful adjustment, whereby the cylinders rise and fall alternately, so that the one not in use passes over the form intact. This machine will work from 1000 to 1200 perfect sheets per hour, and requires but two boys. Mr Napier has constructed several other machines of great merit, one of which, for newspapers, will perfect 2000 sheets per hour by the labour of two men.

Messrs Hopkinson and Cope have also produced a double-cylinder perfecting griper machine adapted for book-work or newspapers. The peculiarity of this machine is, that it is supplied with a set-off sheet apparatus, by which a "set-off sheet" is fed in with each sheet to be printed, which it meets as the latter enters on the second cylinder, and, passing round with it, prevents the ink on the printed side of the paper setting off on the blanket of the cylinder, and being thence transferred to the following sheet. This apparatus can be easily dispensed with when ordinary work is being printed. They have also made a single cylinder griper machine called a "Desideratum." It is supplied with a pointing apparatus, which renders it available for book-work.

Before the invention of cylinder machines, the desire to obtain increased speed led to many ingenious contrivances for accelerating the action and economising the expense of the ordinary printing-press; all of which, however, either failed, or were superseded by the steam machine. There are now in general use, for book-work of a quality superior to that produced by the cylinder, several machine-presses which are in every respect satisfactory. They generally consist of two tables, on each of which a form is laid; these pass alternately under a self-acting platten: while one form is receiving the impression, the other is delivering its printed sheet to the taker-off, and receiving its white sheet from the layer-on. This double operation is effected at the same time, by the frisket being attached to the tympan at the bottom (not at the top as in the common press). When the tympan opens, it falls back inwards; the white paper is laid on the frisket, the tympan closes upon it, it is printed; but when the tympan opens, the printed sheet is made to rise with it, and is taken off while the layer-on is placing another sheet on the frisket. The ink is conveyed to the type by a similar apparatus to that used in cylinder machines. These machine-presses do excellent work at the rate of 600 or 700 impressions per hour, and are made by the same firms as supply cylinder-machines.

The "Scandinavian" machine-press differs from all others in respect that the form of type is stationary, and that the tympan and inking-roller are passed between the form and the platten. As the power required to set this press in motion is much less than that required where the form and table travel, manual labour is sufficient; but only one form can be worked at a time.

These are by no means all the machines that have been devised or brought into use. They are, however, all that it is necessary to mention, as the same principle is common to all. Every maker is at liberty to manufacture almost all of them, with such modifications as his own talents may suggest, the patents, where any were taken out, having, with few exceptions, expired.

(For the Reader's marks of correction, see the article CORRECTION.) (T. C. H.)

PRINTS. See ENGRAVING.

PRIOR, the superior of a convent of monks, or the next under the abbot. *Grand Prior* is the superior of a large abbey, where several heads are required.

PRIOR, MATTHEW, one of the most correct of our English poets, was born at Winburn in Dorsetshire, on July 21, 1664. He was willing to leave his birth and his birthplace unsettled. On his father's death, his uncle, who was a vintner near Charing Cross, took charge of him, and sent him for some time to Dr Busby at Westminster. The Earl of Dorset having found him reading Horace, was so pleased with his proficiency that he undertook the care and cost of his education. He accordingly, in his eighteenth year, entered St John's College, Cambridge. where he distinguished himself by writing a poem on the *Deity*, addressed to the Earl of Exeter, in acknowledgment of a benefaction enjoyed by his college from the bounty of the Earl's ancestor. He published, in conjunction with Montague, *The City Mouse and Country Mouse*, in 1687, in ridicule of *The Hind and Panther* of John Dryden, which gained for both speedy preferment. Prior took his bachelor's degree in 1686, and his master's by mandate in 1700. In 1691 he was sent as secretary to the embassy of the Hague, where he conducted himself so well that he was appointed, on his return, a gentleman of King William's bed-chamber. On the death of Queen Mary in 1695, he added a long ode to the heaps of elegy which already mourned her loss. He was secretary to the embassy at the treaty of Ryswick in 1697, and next year he met with great distinction at the court of France. On his return he was made commissioner of trade. He exhausted all his powers of celebration in the *Carmen Seculare*, published in 1700. King William was the subject; and gratitude dictated what his reason did not refuse. Prior was chosen representative of East Grimstead in 1701, when he seems to have changed his party.

In the succeeding reign war took the place of negotiation, and left Prior to polish his verses. He published soon after a volume of poems, with a high panegyric upon his deceased patron, the Earl of Dorset. In 1706 he was excited, by the victory of Ramillies, to another effort of poetry. The Tories being then in power, and anxious to end the war, employed Prior, in 1711, on the peace negotiations at Utrecht, and he was subsequently induced to go privately to Paris with pacific propositions. He accordingly attended Bolingbroke to the French capital in the capacity of ambassador without the public distinction, and continued to act without a title until the return from Paris of the Duke of Shrewsbury, who "refused to be associated with a man so meanly born," when Prior assumed the style and dignity of ambassador. He was cheated, somehow, of his ambassadorial plate; and in a heroic poem addressed to her Majesty Queen Anne, he makes some magnificent allusions to the loss he had sustained. On the 1st August 1714 he was recalled, and returned as soon as his debts would let him. He was welcomed by a warrant for treason as soon as he had set foot on shore, and was confined to his own house, where he relieved the tedium by writing his *Alma*. On regaining his liberty he was in danger of penury, when his friends adopted the expedient of encouraging him to publish his poems by subscription. The enterprise succeeded; and he now enjoyed the privilege of contemplative tranquillity. He died at Wimpole, a seat of the Earl of Oxford, on the 18th of September 1721, and was buried in the Poets' Corner in Westminster Abbey. Prior's works comprise tales, love verses, occasional poems, *Alma* and *Solomon*. In the opinion of Mr Thackeray, Prior's are "amongst the easiest, the richest, the most charmingly humorous of English lyrical poems." Some of his tales, however, are, to say the least, not over decent.

PRISCIANUS, one of the most celebrated of the ancient grammarians, was surnamed *Cæsariensis*, either because he was born at Cæsarea, or had received his education there. He flourished in the reign of Justin about the middle of the fifth century, and taught grammar at Constantinople, where he received a salary from the court, which makes it probable that he was a Christian. He has left *Commentariorum Grammaticorum libri xviii. ad Julianum*, besides eleven smaller pieces. His grammatical works have been published by Krehl, Leipsic, 1819, in 2 vols.; and his smaller essays by Lindemann, Leyden, 1817.

PRISCILLIANISTS, a theosophic sect, who arose in the Spanish church towards the close of the fourth century, and who professed tenets closely related to Gnosticism and Manichæism. Their founder Priscillian, a respectable and wealthy Spaniard, seems to have received the germ of his doctrines from one Marcus, who travelled thither from Memphis. (See Neander's *History of the Church*, vol. iv.)

PRISM. See GEOMETRY, part ii. § 2.

PRISON: PRISON DISCIPLINE.

This is a department of jurisprudence and administrative science which in later times has totally changed its character, and requires a new method of treatment. From being matter of mere speculation, it has become matter of practice and of induction from observed facts. In earlier editions of the *Encyclopædia* it was treated by one of those accomplished and sagacious inquirers, whose able exposure of existing defects produced the many experiments and improvements which supply the materials of this exposition. Mr Mill found no system of prison discipline acknowledged and acted on, although Howard, Beccaria, and Bentham had preceded him in endeavouring to establish such a system. Hence he thought it necessary to go back to the first principles of punishment, and realize them into rules of practice for the future guidance of mankind. Such a method any man who earnestly threw himself into the subject and felt himself capable of handling it was then quite entitled to adopt, because the practices he had to censure were not caused by false doctrines about prison discipline, but by a general neglect among mankind to search for such doctrines at all, and a consequent dereliction of the whole practice of punishment to accident, routine, or the interests and passions of those invested with power.

But of late years the efforts of the leaders of civilization have borne with practical effect on this branch of the science of government. However they may be open to criticism as more or less excellent or imperfect, the various methods of punishment have been carefully and conscientiously studied. And this study has not been merely theoretical, but has been a continuous commentary on practice and its results, those having most to do with the actual administration of punishment having been the fullest expounders of its rules, through parliamentary reports and other published statements. Hence it would be unbecoming, were it profitable, at this time to embark in pure theories of prison discipline. It is apprehended that it will be more acceptable to tell what has been done by the leaders of prison reform, and to give an account of the results of their efforts, so far as these can be ascertained.

It is proper, in the first place, briefly to note the extent of the field now occupied by the term *prison discipline.* It has been ever widening, and now nearly occupies every department of punishment in this country and throughout civilized Europe. Such other corporal punishments as are now inflicted are additions to the punishment of imprisonment. Where the law can be satisfied by a forfeiture of money or property, imprisonment is still the alternative by which it is extorted. Where, as in the case of the soldier, chastisement is spoken of as a degrading punishment which it is desirable to supersede, imprisonment appears as the only available alternative. Forced labour of any kind is but a form of imprisonment. Simple banishment is now almost unknown. With transportation imprisonment was always closely co-operative, as the means of detention until the convict was removed, and as the sanction for keeping him in order in the penal colony. Since transportation has been virtually abolished as a punishment, imprisonment has received a corresponding enlargement. The penal serf is a prisoner, although in certain stages of his long punishment he is permitted to spend a portion of each day in the open air. Nay further, reformation having become a distinct object of penal discipline, has suggested the establishment for the young of institutions in which the reformatory prevails far above the penal element; but these are at the same time institutions of restraint or imprisonment. There is no broad line of distinction between reformatories and prisons, and the nature and management of both come naturally under the head of "Prison Discipline." There remains only capital punishment, now fortunately so rare. Here, too, the prison is necessarily brought into use, since the criminal must be kept there until he is put to death. But prison discipline has a far more important connection with capital punishment. It is admitted on all hands that the infliction of death is to be avoided wherever other means can be found of punishing with equal effect. It is to the resources of the science of prison discipline that we must look for such effective punishment; and thus it is one of the services of this science to reduce, if it should not even some day be able to supersede, a method of punishment so inimical to civilization.

Ancient practice.

The prison, as we now know it, is as entirely an institution of modern Europe as the church, the school, and the poor-house. Words occur, connected with events and customs in the ancient world, which we can only translate into modern language or thought by the use of the word "prison;" but the thing, as we now know it in the shape of the county jail or the convict prison, was then neither known nor anticipated. People were put in chains, or even locked for a time within stone walls; but systematic committal to prison as a specific punishment, in the way in which a vagrant is sentenced to thirty days, or a thief to twelve months, is a thing of which it may safely be said that no trace can be found in the practices of ancient nations which have come down to us. We are told how "the princes were wroth with Jeremiah, and smote him, and put him in prison in the house of Jonathan the scribe, for they had made that the prison." (Jer. xxxvii. 15.) This is one of the many instances occurring in Scripture where a temporary prison was found in any large house where a person could be conveniently restrained. Travellers in the East notice the same arrangement still. Systematic prisons are seldom known; but civil liberty is held cheap, and any one who is strong enough may detain a casual prisoner. Our representatives at eastern courts, finding it extremely inconvenient that they cannot get culprits of their own nation punished according to the British practice in public prisons, are accommodated with prisons of their own as a part of the ambassadorial establishment, in pursuance of the policy of orientals, which allows foreigners sojourning among them the practice of their own institutions. Though there are some instances in Scripture where the prison is spoken of as a punishment in itself, yet its proper use was that of mere temporary custody, that the prisoner might be forthcoming for ulterior purposes; and imprisonment is not laid down as a specific punishment in Leviticus or elsewhere. The imprisonment of Joseph in the king's prison until judgment should be passed on him, has been sometimes mentioned in illustration of the high civilization and just laws of the Egyptian empire. Instead of being summarily punished by the high officer whom he was charged with injuring, he was committed for trial, like a British culprit of the present day.

Greece.

That the Greeks were far from having an established system of imprisonment is shown by this, that there are several words in the language which may be translated by the word prison, but which each possesses several other meanings. Anything resembling an actual prison seems chiefly to have been employed among them in detaining citizens until they paid penalties or debts to the state. They had methods of public exposure in bondage, like the stocks or pillory. Slave labour in rowing galleys, a frequent punishment in later times, seems to have been in use among them, and a people so maritime in their habits would have an abundant demand for such labour. But where the privileges of citizenship were so important, afflictive punishments among free men were rare, loss of caste and position being a formidable penalty. Hence banishment was a favourite punishment. That peculiar form of it called *ostracism* is well known, and though so generally deemed odious, has been ingeniously defended as a mild remedy by which the state got rid in good time of any ambitious citizen, whose growing power, if permitted to culminate, might end in revolution and outrage.

Rome.

The student in the Roman law cannot help remarking the extreme meagreness of its penal department, whether he compare it with the vast and magnificent organization of the Justinian law of civil rights and obligation, or with the elaborate provisions of modern penal systems. In the Justinian law, indeed, the chief attention given to crimes is for the purpose of expounding the civil rights of action and possession arising out of them. Questions how far crimes and punishments may affect property and rights of succession are matters of elaborate inquiry, while the cursory and fragmentary manner in which the law relating to criminals and their treatment is set forth, shows how small were the claims which this portion of the administration of justice held on the attention of those great masters of jurisprudence, who, in the other departments of law, dictated the fundamental principles of legislation to all the nations of modern Europe. The department of the code which treats of punishments (lib. ix., tit. 47) consists of a few paragraphs, which read more like casual notices of peculiar provincial practices, than an official announcement of the laws of an empire. Nor is the enlarged statement of the law of punishment contained in the digest much more satisfactory (lib. xlii., tit. 19). The analytical spirit which ever pervades the Roman jurisprudence here develops itself in artificial classifications and arrangements. But these are entirely arbitrary, referring to the nomenclature of the punishments, and the classes of persons who may respectively be subjected to them; while the proper objects of punishment so sedulously kept in view at the present day leave scarcely a trace of their having influenced the penal lawyers of the empire. Perhaps the only instance in which the demoralizing influence of a punishment was seriously considered in dealing with it, is to be found in the rule, that women were not to be put in prison or committed to the custody of troops.

A powerful instrument of punishment towards the free citizen was available in the three grades of *capitis minutio*, or loss of caste. The first was the loss of *familia*, or of the privilege of membership of the family; and if the criminal were the *pater familias*, or head of the family, he thus lost his authority not only over the minor members, but over the herd of *familiares*, or slaves, more or less numerous according to the wealth of the *familia*. The next *minutio* was the loss of citizenship; the third was the loss of liberty;—and at this point, the man becoming a slave and a mere chattel, the state was no longer troubled with his disposal, unless he committed some atrocious crime. The Romans not only banished out of any particular part of the empire, but they also transported criminals to some spot where, like our own convicts, they were forced to remain. *Relegatio in insulam*, or transportation to an island, was a favourite form of this punishment. They had several forms of penal labour, in which the convicts might be fettered or unfettered,—a distinction which was always counted very material, though it seems to have depended more on the rank of the convict than the character of the offence. Some of the establishments for penal labour were connected with the great water-works of the Romans. A far larger number, however, were in the mines, the condemnation to the *metella* being a standing form of punishment. Penal labour was sometimes carried out also in quarries; and in Cicero's charge against Verres we have a powerful description of the *latomiæ*, or prison quarries of Syracuse, whence the stones were taken to build the town and harbourworks: they seem to have resembled, in external characteristics, the convict establishment of Portland, with its quarries and breakwater.

To how little an extent the prison, in the modern meaning of the term, was used by the Romans, is evident from the great historical importance attributed to the one remaining relic of a Roman prison in the subterranean chambers known to the present day as the Mamertine Caves. They consist of two vaults, an upper and an under. The former covers an area of 33 feet by 22, the other a semicircle at a radius of 22 feet. Supposing these to be very ancient, as Italian antiquaries maintain that they are, they coincide aptly enough to the descriptions of old writers, who speak of the caves as lightless, airless, and impregnated with deadly odours. In such a place no considerable number of prisoners could have been confined,—no one prisoner could have lived long. The prisoner committed to it was put there in fact not to be imprisoned, but to undergo the punishment of death. Often he was merely detained there while the preparation for his execution went on outside; in other instances the place itself was left to do the work of death, accomplished partly by starvation, partly by smothering in foul air. We are told by Livy, that Ancus Martius, an account of the growing wickedness and audacity of the citizens, built a prison overhanging the Forum. If the upper vault was a part or the whole of this prison, the lower is attributed to Servius Tullius, after whom the prison was called the Tullian. Above these vaults was raised a lofty erection called the Robur, which seems to have been a gigantic tower or scaffolding of oak, from the top of which criminals were precipitated, as others were from the Tarpeian rock. It was in the Tullian that Jugurtha was starved to death. Lentulus and the other abettors of Cateline were strangled, according to Sallust, in the prison called the Tullian, as you ascend to the right, where there is a depression of the ground,—a place terrible for its darkness and evil odours. There is yet another stage in the celebrity of these rude caverns. The apostle Paul, who tells us that he lived in Rome in his own hired house, in charge of a centurion, is held by the traditions of the early church to have been afterwards put in prison along with St Peter. This belief having been once established, there was no other place which could be assigned as their prison but the old Tullian. Hence the caverns are consecrated ground, and have received the visits of many devout pilgrims.

A set of very significant buildings, scattered over the Roman empire, called *ergastula*, must sometimes have had considerable resemblance to very bad modern prisons. They were used for the punishment of criminal and refractory slaves, but also, and probably to a far greater extent, as places of safe custody for newly-acquired slaves, or for those who were too much in excess of the free population of the district to be safely allowed freedom of motion. When we remember the large bodies of men, taken often from the higher ranks of society, endowed with great daring, and expert in the use of arms, who were drafted into the ever-accumulating mass of the Roman slaves, we must suppose that these *ergastula* were often buildings of great strength and well guarded. But like the property they contained, they were of course chiefly in the hands of persons who administered them according to their own private will and judgment. It is indeed in this great offensive feature of Roman society that we shall find the reason why the penal department of the law could even with bare safety be so lightly passed over. The institution of slavery threw into private hands the performance of by far the greater part of this department of work, and to a corresponding extent relieved the state. The administrators of the imperial law had little further trouble with the offender who had reached the condition of slavery. To be committed to slavery for a fixed period, as offenders are now committed to prison, was, were it practicable, never thought of. Hence there was no measure of the punishment to the offence, and no distribution of separate punishments for separate offences. The slave was permanently doomed to his fate. The criminal slaves thus became a class into which men were drafted rather for their general character and conduct, than to be punished for specific offences. Personal influence or clientage would do far more to save from such a fate than innocence. It becomes at once clear that when there were such opportunities for removing criminals beyond the management of the state, there was little inducement to the state to trouble itself, as it now does, with the discussion of niceties of prison discipline. An arrangement which professes to put the bad part of the population into the hands of the good as their owners and masters, has always fascinated by its simplicity and its apparent efficiency. It caused the late master of positive philosophy, August Comte, to maintain that the institution of slavery was the greatest single step in the progress of human civilization, since it superseded a great amount of slaughter, with or without cannibalism. The same spirit influenced the English vagrancy laws of the reign of Henry and Elizabeth, and we shall see how deeply it tainted the earlier stages of the transportation system. Nay, its history and tendency are rendered worthy of attention, through efforts partially to revive it in our own country at the present day, by projects for abandoning to some extent the strict just principle of English jurisprudence, which always finds an offence committed before a punishment is awarded, and for subjecting all persons of bad character and habits to a partial slavery to the police authorities.

The manner in which this absolute slavery of the Romans was pressed out by the modified serfdom of feudalism, which in its own turn gradually merged into the freedom now enjoyed by a large portion of Europe, is an interesting historical problem, having so far reference to the present matter that it is intimately connected with the origin of prisons. It will be seen, indeed, that these institutions, now among the most important objects of politics and jurisprudence, arose quite fortuitously in the hands of men who never dreamed either of repressive or reformatory discipline, and scarcely ever formed to themselves the rudest notions of afflictive punishment. We shall find that thus modern Europe was covered with prisons long before it occurred to any one to think that there was some determinate object to which they should be applied. This is a fact remarkable and important, because, although it is upon the prison—either in a pure or modified shape—that the eyes of all penal reformers ever rest as the means by which repression and reformation are to be carried out, yet few remember that it has not been by any process of induction, or from a general examination of all known or possible methods of repression and reformation, that the prison thus exclusively occupies the field, but because some fortuitous events in feudal history brought the building so named into existence as a feature of the social system of Europe.

This feature did not make its appearance until long after the fall of Rome. In the properly dark age—the period of transition—edifices built for safe custody were probably still more scanty than in ancient Rome. The temporary and fragile structure of the houses of that period, and the character even of the fortifications, which were only similar houses surrounded by ditches and mounds or low ramparts, were not consistent with the existence of strong stone chambers.

Feudal origin of prisons.

That great movement throughout Europe in the tenth and eleventh centuries, sometimes called the migration of the Normans, created the baronial or feudal system, and at the same time established prisons. It was then that the castle became a distinctive feature in the social system, and it is the peculiarity of the castle that it is in combination a house, a fortress, and a prison. In the Roman empire the institution of slavery was, as it now is in America, a vital matter, ever affecting the safety of the mighty machinery of the empire, and demanding the utmost vigilance and energy of the executive to keep the upper hand, and prevent the slaves from entering on a death-struggle for mastery. Hence the slave-owner had the whole force of the executive at his back to support his power over his slaves. But the feudal lord was in a great measure left to himself, both for protecting the lands of which he was the feudatory, and for coercing his vassals; and for both purposes the prison castle was to him a useful institution. Under the earliest Norman kings England was covered with castles, and the invasions of their successors scattered them over Wales, Scotland, and Ireland. All of these edifices had a more or less amount of prison accommodation; and we take the term dungeon, generally employed towards a prison as a term of censure, from the *donjon*, or principal tower of a Norman fortress. As there were castles of all sizes, from those of an independent monarch or a reigning duke downwards, so were there prisons; and even in the humblest square tower, built by the petty landowner who had two or three over-lords between him and the crown, the dungeon or prison-vault was an indispensable feature. In the ruins of old castles on the Rhine and elsewhere the dungeons are ever a well-known feature, interesting from the romance naturally attached to them. Perhaps the most remarkable remains of the kind are those under the new palace of the dukes of Baden at Baden-Baden. They form a series of vaults in the rock far below the ground, smoothly cut, and dry; and they have this remarkable feature, which makes them terrible almost to the visitor going through them with a guide, that the door of each is a mass of solid stone swinging smoothly on a pivot, and closing so as scarcely to leave a perceptible trace of its outline.

In the later stages of the feudal system, the existence of any asserted right of imprisonment was, like many other prerogatives, the object of contention between the greater and lesser feudatories. It was jealously guarded, by those who could hold it, as a material symbol of power. It was largely exercised by the church, and was stoutly arrogated by the municipal corporations as a privilege belonging to their station in the feudal hierarchy. Even in this country at the present day traces might be found of the arbitrary distribution thus made of places of punishment through their feudal origin. The actual vaults in which the abbot or the baron of the sixteenth century confined his victims would not now be tolerated as places of punishment; yet, almost down to the present generation, the feudal castles were the actual prisons in such places as Oxford, Cambridge, Norwich, Lincoln, Lancaster, Worcester, and Caermarthen. In Scotland there was, until lately, a crowd of little prisons, which, although existing in towns, were the appendages of some feudal estate, holding rank as a barony or regality. Their dungeons, like other portions of their fortresses, sometimes excited the fastidious attention of the princes and nobles of the middle ages; and the chief object of this attention was to bring their potency for cruel infliction up to the highest possible point. There were many eccentric inventions directed towards this end, such as the kind of iron cage in which Louis XI. shut Cardinal Balue and the son of the Duke of Alençon. In such dens, too, if the ordinary sources of history are to be credited, Edward I. shut up the sister of Robert

Bruce, and that Countess of Buchan who had assisted at the Scottish king's coronation. Of receptacles like these few vestiges of course are preserved; but the dungeons which remain, built of solid stone or cut into the living rock, are often of a character to make those who have any respect for the promulgated laws of vitality question that human life could have found support in them. Such are the *pozzi* or wells in the ducal palace of Venice, described by Sir John Hobhouse in his notes to *Childe Harold*. In these, and such as these, however, pits in solid masonry or the solid rock, with no circulation of air, it seems certain that many a captive dragged out a protracted existence. There were other smaller pits, which have been called *oubliettes*, generally bottle-shaped, with narrow mouths, broadening downwards, in which it is certain that the victims could not live, and into which, indeed, they must have been dropped to die by suffocation. These were favourites with the church as a means of death without bloodshed, and received the name indicative of their deadly purpose—*vade in pace*. The next and more humane stage was, building the victim into a niche in a wall, where suffocation would be much more speedy.

British and continental practice.

It would obviously be a vain task to estimate the amount of cruelty and injustice executed through the edifices constructed for oppression thus thickly scattered over Europe. The instances revealed in general and local history, and in criminal trials, only suggest the existence of a far larger crowd of victims, whose unknown fate will remain so until all secrets are laid bare. It is one of the many instances of that marvellous sagacity with which the liberty of the subject has ever been guarded, and its lurking enemies detected, in this country, that the earliest proceedings of a constitutional character seek to provide remedies against arbitrary and illegal imprisonments. The protection of the subject from imprisonment, otherwise than in due course of law, is one of the requisitions of the great charters, and the object was pursued with ceaseless vigilance through the passing of the Habeas Corpus Act in the reign of Charles II., down to the almost perfect system of protection possessed at the present day. Our familiarity with this system lessens its importance in our eyes, and we are apt to forget that it is a national peculiarity. It consists of two distinct parts. One is the rule, that no person can be committed to a prison unless a warrant for his imprisonment has been granted by a magistrate. An accused person is liable to detention by the officer of justice who apprehends him, but he is in the personal custody of the officer, even should he use a strong-room or lock-up to assist him in the detention. It is the policy of the law to offer such a custodier few facilities for long detention, that he may the sooner bring his captive before a magistrate, and especially he cannot place him within the walls of an actual prison until such a warrant is obtained. The next security is the habeas corpus, or right to demand a trial, and have the advantage of innocence, or be subject to the fixed legal punishment of guilt, as the result may be. In no other country do such safeguards appear to have presented themselves, though occasional attempts have been made to imitate them. Where there are such constitutional protections, the proper registers of admissions and liberations, with every particular necessary for the identification of each prisoner, and his enjoyment of his legal rights, cannot be neglected without great peril. In countries where there are no such constitutional safeguards of liberty, the best devised systems of official routine will sometimes go wrong or be neglected, and acts of injustice will be unwittingly committed; but in despotic countries it has often been matter of state policy that all means of identifying persons immured in prison should be erased, so that from the moment of their apprehension they cease to belong to the living world, and their actual death is no event to any human being but the prison officers surrounding them. One man thus mysteriously isolated came from incidental circumstances to be an object of much interest—"the man with the iron mask;" and several books have been written, in the vain attempt to discover who he was. This prisoner was confined in the Bastile, which, with the *lettres de cachet*, or royal warrants by which prisoners were received into it, became as the type and representative of arbitrary imprisonment, odious both in France and Britain. Yet in this great state fortress the registers seem to have been preserved with more than usual care, and it was less likely than many others to be the living tomb of men committed to oblivion. These registers were found when the Bastile was destroyed, and much instructive matter was derived from them. Nor was severity always the rule in this dreaded fortress,—it was the scene often of luxury, gaiety, and dissipation. What chiefly excited indignation towards it was the reckless, easy manner in which the fatal *lettres de cachet* were granted, to gratify the ambition of mistresses, or to further personal malignity or caprice.

There are traces at early periods in French history of attempts to obtain judicial checks on the power of imprisonment. In the reign of Louis XIV. a promise was extorted by the Parliament that the case of every prisoner should be brought under judicial cognisance within twenty-four hours after his committal. The first revolution was inaugurated with strong resolutions against arbitrary and indefinite imprisonments, which produced no better practical result than the release of the sufferers then in bondage. France has never possessed any such thoroughly practical a protection as our habeas corpus. There, as well as in the other great European states, there are doubtless enlightened regulations emanating from central authority for obviating any sufferings from the enmity or the carelessness of the inferior officers of justice. But there are no checks on the central power itself; and this is still the only country where there is in the law a power separate from the executive which can open the door of every prison. Through these means the liberty of the subject has among us from time immemorial been zealously guarded by constitutional checks on the power of imprisonment.

Defects in English system.

The next stage is the protection of the prisoner from neglect and cruelty after he is legally within the walls of a prison; and there is reason to fear that in this department we were long behind those governments where everything is managed by official routine, springing from a central authority. At all events, from the mere want of responsibility and control, it is certain that there have been scenes of lawless violence and of cruelty in British prisons, which have been as pregnant with suffering to the victims as any enforcement of the decrees of a tyrannical autocracy in a secret dungeon could ever be. In the reign of George I. a rumour spread in which the keepers of the chief prisons of London were charged with cruelty. Colonel Oglethorpe brought it before the House of Commons, and obtained a committee of inquiry. The committee went straight to the prisons themselves to make their examination. Hogarth has a picture representing them in a grated dungeon of the Fleet: they are seated, some of them in court dress, at a table hastily adjusted for the transaction of business. Some hideous instruments of torture are lying on it. A half-naked prisoner, with one of these instruments on his head, is under examination; and the keeper Bambridge stands before them as a detected criminal, angry and terrified. Bambridge was a man of a savage and grasping nature, who, on whatever condition of life he had been cast, would have never permitted humanity to interfere with his interests. He bought the office of warden of the Fleet, and wanted to make the most of his bargain. His chief victims were among the debtors who had anything to part with; and if they resisted his rapacity, as many of them did, he used the power unfortunately in his possession to carry on with them a war of extermination. But it was not the rapacity and cruelty of one man that created the abuses of these London prisons, but a general absence of control, and the like cruelties were practised in them throughout. The committee stated it to have become a general practice of the keepers "unlawfully to assume to themselves pretended authority as magistrates, and not only to judge and decree punishments arbitrarily, but also to execute the same unmercifully." Among these unmerciful exercises of an illegal power, the following may be taken as a specimen from the committee's report:—A general attempt had been made to escape from the Marshalsea, and those implicated in it were taken to the marshal's lodge for examination and punishment. "One of them was seen to go in perfectly well, and when he came out again he was in the greatest disorder; his thumbs were much swollen and very sore; and he declared that his being in that condition was that the keeper, in order to extort from him a confession of the names of those who had assisted him and others in their attempt to escape, had screwed certain instruments of iron upon his thumbs so close that they had forced the blood out of them with exquisite pain. After this he was carried into the strong-room, where, besides the other irons which he had on, they fixed on his neck and hands an iron instrument called a collar, like a pair of tongs; and he being a large lusty man, when they screwed the said instrument close, his eyes were ready to start out of his head, the blood gushed out of his ears and nose, he foamed at the mouth, the slabber went down, and he made several motions to speak, but could not. After these tortures he was confined in the strong-room for many days with a very heavy pair of irons, called sheers, on his legs." (*Parl. Hist.* viii. 740.) Such a narrative occurring in the report of a parliamentary committee after the accession of the House of Hanover, is at variance with popular notions of the progress made by England in humanity and civil liberty. The committee were deeply excited by the iniquities which they had to expose, and perhaps exaggerated them. But the instruments of torture—the thumb-screw, the collar "like a pair of tongs," and the "sheers"—existed, and had doubtless been made that they might be used. The committee, indeed, accused these keepers of still deeper acts of cruelty, and among others of a like kind, brought against them the following charge, which reads like an imitation of the classical model of Mezentius, who chained the living to the dead. "One particular instance of this sort of inhumanity was of a person whom the keepers confined in that part of the lower ward which was then separated from the rest, while there were there two dead bodies which had been there four days; yet was he kept there with them six days longer: in which time the vermin devoured the flesh from the faces, eat the eyes out of the heads of the carcases, which were bloated, putrid, and turned green during the poor debtor's dismal confinement with them." (*Parl. Hist.* viii. 741.) Bambridge and another keeper were tried for murder, and acquitted. The advisers of the crown naturally hesitated to bring the whole weight of a bad, neglected system on even the worst of the mere instruments who carried it out. The blood of the English people was up, however, and individual prosecutors pursued these men with relentless tenacity. They were subjected to the rare and peculiar action of "appeal for murder," and in the end narrowly escaped with their lives.

Progress of improvement.

It is probable that after this inquiry the keepers of prisons became cautious, and avoided illegal cruelties; but nothing was yet done to mitigate the ravages, physical and mental, of which the very structure of the prisons rendered them instruments, until the days of Howard, whose labours and their results are a historical epoch in prison discipline all over the world. (For an account of his mission we refer to the article Howard.) Perhaps the portion of his revelations which not the least astonished his countrymen was the superior cleanliness and order of those places of detention in continental despotisms, which our national pride could only think of as noisome dungeons, where the victims of tyranny groaned in their chains. His visit to the prisons of the Dutch was a real luxury to Howard. That thoughtful, industrious, and humane people had, without promulgating any great leading philosophy in prison discipline, gradually found their way in simple practice to institutions which in their features of industry, order, and cleanliness, bear a closer resemblance to the best prisons of the present day than any others have done.

But in England the reform, even after Howard's exposure, was so slow and partial that there are prisons around which some of the evils condemned by universal acclamation, when he exposed them in 1774, still linger. We have an account, more dreadful even than his, because more picturesque, from Mr Buxton, of the result of inquiries into the condition of English prisons, published in the year 1818. Along with a statement of corroborative facts seen by him in the various prisons, he gives the following description of the position of a person—guilty or innocent—whose misfortune it is to be committed for examination to a London prison:—"At night he is locked up in a narrow cell with perhaps half-a-dozen of the worst thieves in London, or as many vagrants, whose rags are alive and in actual motion with vermin. He may find himself in bed, and in bodily contact between a robber and a murderer; or between a man with a foul disease on one side, and one with an infectious disorder on the other. He may spend his days deprived of free air and wholesome exercise. He may be prohibited from following the handicraft on which the subsistence of his family depends. He may be half-starved for want of food and clothing and fuel. He may be compelled to live with the vilest of mankind, and, in self-defence, to adopt their habits, their language, and their sentiments. He may become a villain by actual compulsion. His health must be impaired, and may be ruined by filth and contagion; and as for his morals, purity itself could not continue pure, if exposed for any length of time to the society with which he must associate." (Buxton's *Inquiry*, p. 17.)

The renowned crusade of Mrs Fry at this time afforded the world an astounding glimpse into the condition of the London prisons. It was on the female department of Newgate that her energies were concentrated. There she found nearly three hundred women, tried and untried—some sentenced to death—in two rooms. "Here they saw their friends, and kept their multitudes of children; and they had no other place for cooking, washing, eating, and sleeping. They slept on the floor, at times one hundred and twenty in one ward, without so much as a mat for bedding; and many of them were very nearly naked. She saw them openly drinking spirits; and her ears were offended by the most terrible imprecations. Everything was filthy to excess, and the smell was quite disgusting. Every one, even the governor, was reluctant to go among them." (Buxton's *Inquiry*, p. 126.)

Mrs Fry's Christian efforts to instruct these poor creatures, and impart to them the consolations of religion, are well known. It was believed at the time that her personal risk was literally the same as if she had gone into a den of beasts of prey, and she is entitled to the full honours of the courage she displayed, although later experience of the prison world may render us less surprised at the thankfulness and docility with which she was received. Among criminals in a prison, with their many sources of anxiety and terror, their over-stretched nerves, and their hopeless feeling of dependence on the will of others, whoever appears with the character of authority and beneficence is likely to be welcomed with thankfulness and homage. When the danger was encountered, and the unexpected results were made public, it was a natural fallacy to suppose, that the impassioned penitence and eager craving for religious consolation represented a change of heart, and the simple way had at last been found for taking by storm the secret fortress of crime. When services such as Mrs Fry's, however, were more uniformly performed, their influence, though of eminent importance, was found to have its limit. That such meteoric efforts should have from time to time fed the public and the fashionable world with episodes of lively interest, is one of the saddest reproaches to our prison administration. What Mrs Fry did for these prisoners, with a great heroic effort, was what should be always quietly doing in every prison by those to whom it is a fixed duty.

Long after this period, from the indifference or self-willedness of the local managers, a large number of the English prisons remained almost unaltered. The prisons of the metropolis continued to be the most conspicuous for mismanagement. In their first report, issued in 1836, the inspectors of prisons said of Newgate:—"The association of prisoners of all ages and every shade of guilt in one indiscriminate mass, is a frightful feature in the system which prevails here; the first in magnitude, and the most pernicious in effect. In this prison we find that the young and the old, the inexperienced and the practical offender—the criminal who is smitten with a conviction of his guilt, and the hardened villain, whom scarcely any discipline can subdue—are congregated together with an utter disregard to all moral distinctions, the interests of the prisoners, or the welfare of the community." And nine years afterwards they say in their tenth report—"We are compelled by an imperative sense of duty to advert, in terms of decided condemnation, to the lamentable condition of the prisons of the city of London—Newgate, Gilt-spur Street Compter, and the City bridewell—in which the master-evil of goal association, and consequent contamination, still continues to operate directly to the encouragement of crime."

It is remarkable that in the present year (1859), it was officially announced to the world, that in the male department of the prison of Newgate arrangements were at last made for keeping the inmates apart from each other. The ordinary, in his first report after this resolution, to the lord mayor and aldermen, said,—"I find the result at present to be not only the entire suppression of the corrupt and demoralizing effect of indiscriminate association, but a peculiar seriousness of demeanour is produced by separate confinement, which, except in a few instances, I never witnessed before." It still remains to carry this improvement into the female department—the scene of Mrs Fry's labours.

The English prisons did not in the meantime remain free from the suspicion of abuses more positive in their character than the mere neglect to reduce them to proper discipline. In many instances it was said that the prison, by the known profusion and luxury prevailing in it, not only failed to terrify the criminal, but proved a disheartening and deteriorating example to the honest, frugal workman. In other cases it was maintained that prison officers, feeling the absence of strict control, indulged in violence and cruelty. So lately as the year 1853 the borough jail of Birmingham encountered formidable charges of this kind, and the difficulty of establishing the truth was a memorable illustration of the necessity of a powerful external control over the conduct of prison officers. In this instance the investigations of the visiting justices and of the inspector of prisons were alike ineffective, and at length a commission of inquiry brought out the facts. At an earlier period the governor of the prison was a man who had obtained eminence for promulgating principles of prison discipline which possessed many good features, but were supposed to require too confiding a reliance on the latent goodness of the criminal class. The visiting justices of Birmingham entertained a suspicion that their prison was made the experimental laboratory of an amiable enthusiast. A reaction took place, and they displaced their governor, appointing a man of different character. He was a navy officer, passionate and imperative, who carried to his duty the one ruling principle, that he was not to be contradicted or baffled, but that what he willed should be enforced, at whatever cost. Hence he endeavoured to break the resistance of obstinate prisoners by sheer cruelty. His conduct was investigated, and narrated at length by the commission of inquiry. One form of infliction described by them, carried out by means of stiff neck-stocks, may be taken as an example:—"They were of various sizes, but those which appeared to have been most commonly used were about 3½ inches deep at the deepest part in front, somewhat more than 13 inches long, and rather less than a quarter of an inch thick, made of leather perfectly rigid. Very speedily after their introduction into the prison, they appear to have been converted into ordinary implements of punishment for non-performance of prison labour or breaches of prison discipline; the prisoner being first muffled in the strait jacket, having his arms tied together on his breast, the leather stock fastened tightly round his neck, and being, moreover (when the punishment was inflicted by day), in almost every case strapped to the wall of his cell, in a standing position, by means of strong leather straps passed round the upper parts of the arms, and fastened to staples or hooks in the wall, so tightly as to draw back the arms into and keep them in a constrained and necessarily painful position, at the same time compressing them. . . . So strapped to the wall, prisoners—chiefly boys—were kept for periods of four, five, or six hours, and in some instances for a whole day, by way of punishment for the non-performance of the crank labour, and for other prison offences chiefly of a trivial character. This mode of punishment, which was of ordinary and indeed daily occurrence in the prison during the year 1852 and the early part of 1853, which was unquestionably altogether illegal, and was of a very cruel, painful, and irritating nature, was adopted and practised by the governor, Lieutenant Austin, entirely of his own authority, without the sanction of the visiting magistrates, and to a great extent without their knowledge."

Legislation as to prisons in England.

The first legislative step in prison reformation in England was taken in 1773, by the passing of two acts, the first-fruit of Howard's labours, one of them for abolishing prison fees, and the protracted confinement of prisoners till these were paid; the other for improving the sanitary condition of the jails. Five years afterwards, a still more decided step was ostensibly taken in the passing of an act (19 Geo. III., c. 74) for the establishment of a penitentiary. It was the joint production of Howard, Sir William Blackstone the commentator, and Mr Eden, a great authority of that period in all matters connected with crime and pauperism. The object, as emphatically laid down by Blackstone, was, "by sobriety, cleanliness, and medical assistance, by a regular series of labour, by solitary confinement during the intervals of work, and by due religious instruction, to preserve and amend the health of the unhappy offenders, to inure them to habits of industry, to guard them from pernicious company, to accustom them to serious reflection, and to teach them both the principles and practice of every Christian and moral duty." This act, however, remained dormant. Its immediate object was to meet, by a penitentiary system at home, the difficulties occasioned by the stoppage of transportation to America. The Australian system was, however, substituted in the manner stated farther on, and the project of a penitentiary was abandoned. The idea was afterwards taken up by

Bentham, and urged with untiring zeal in his *Panoptican Penitentiary-House* and other works. He had a great love and reverence for Howard, whose pupil he professed to be in matters of prison discipline. But his publications teem with original ideas and practical inventions of his own, and he grouped them together so as to present the world with every feature which such a building should possess, and every rule applicable to its discipline and working, down to the minutest particular. It is denied to the human intellect to possess the faculty of absolutely forecasting the results of experience, and proving, step by step, where they are to lead; and hence the systems of discipline to which the world has groped its way, through slow experiment, have in a great measure differed from Bentham's anticipations. But there is, at the same time, between them a sufficiency of coincidence to bestow on these a character of marvellous sagacity, and to make them profitable reading to the practical disciplinarian. Bentham offered to enter on a contract with government for the detention of 1000 convicts; and an act of Parliament was passed in 1794 to carry out the project, but again the act remained dormant. In the meantime there were many parliamentary inquiries into prisons and prison discipline. The building of the great penitentiary of Millbank, which now contains accommodation for 1300 prisoners, was begun in 1819. In 1822 a committee was appointed to revise the whole of the law as to jails in England and Wales, and the act 4 Geo. IV., c. 64, still the leading statute for the English local prisons, was passed. By that act a direct communication was opened between the secretary of state and the several administrators of prisons, over whom he has continued to exercise a limited control, and returns were periodically required to be made to him relative to the discipline and condition of the various prisons, which were laid before Parliament. An act was passed in 1835 (5 and 6 Will. IV., c. 38), giving a further central control over prisons. Among other provisions, it gave the secretary of state the power to revise and alter the rules of all prisons. It provided for the appointment by the crown of inspectors, authorized to inspect periodically and to report upon all places in which persons can legally be confined—one of the most important of the safeguards against irregularity or abuse which the legislature has hitherto created. Soon afterwards, the gradual decrease, and in the end the almost total abolition of transportation, rendered necessary the large convict establishments to be subsequently referred to. With great deliberation, and after much inquiry, the plans of the prison of Pentonville were adopted in 1842, as those of a model prison, calculated to meet all the requisites of prison discipline which the science of the age had devised. Parkhurst had been established in 1838 for young offenders; and to these were added the establishments of Portland and Portsmouth, Dartmouth, Chatham, and Brixton.

Hulks.

It is proper, as part of this brief history, to state that from an early period the deficiency of prison accommodation for convicts before their removal had rendered it necessary to find some other receptacle for them, and unfortunately none better suggested itself than the hulks of old abandoned war-ships. It was necessary subsequently not only to detain in them convicts awaiting their term of removal, but convicts for the shorter periods, such as seven years, during the whole period of their sentence. In the hulks numbers of the most hardened offenders were herded together for years, with such consequences as may be readily conceived. There is scarcely any defect in penal discipline of which these establishments were not flagrant and steady examples. A professed necessity kept them in existence during a long period of public condemnation, which was almost universal. They have only lately been abandoned, and their example is not likely to be again followed.

Scotland.

In the meantime, in Scotland, almost all the characteristic defects of the English jails flourished in an exaggerated shape. A parliamentary inquiry into the state of the Scottish prisons occurred in 1826, but the first legislative relief was accomplished in 1836, when the prisons were brought, like those of England, under the eye of a government inspector. Mr Frederic Hill, the first person appointed to that duty, summed up in the following terms the defects which he found:—"Want of the means of separating prisoner from prisoner, and of preventing intercourse from without; want of employment, and of provision for teaching the prisoners a trade or other occupation by which to earn an honest livelihood when restored to society; want of mental, moral, and religious instruction, insecurity, the luxurious diet, and the life of ease in some prisons when compared with the food and labour of the lowest class of honest and industrious people; great expense of many of the prisons; incompetency of many of the keepers; want of female officers; want of the means of inspection; want of cleanliness and ventilation; sloth and injury to health, induced by the long time the prisoners pass in bed, and want of a uniform system." Escapes were very frequent. From a national distaste at the infliction, as well as the endurance of restraint, there was a laxity about external communication, which would have seemed strange in England, even before the improvement of prison discipline there. The inspector in his second report, in reference to one of the northern prisons, after mentioning that a prisoner had been allowed to attend a public meeting, said,—"It is stated that prisoners were sometimes allowed to go to supper parties, and this with the key of the prison in their pockets, in order that they might return without disturbing the jailer. A gentleman whom I met sometime after leaving Dingwall told me, that happening to be at that town once on the market-day, and standing at the window of the inn opposite the jail, he was amazed to see a large fish apparently running up the wall of the prison. The fish having reached one of the upper windows, disappeared; and it then occurred to the astonished spectator, that the fish owed its ascent to the assistance of the inmates, and in this view he was confirmed by the sight of a cord with a hook at the end, which he saw descending from the prison window. A boy who was stationed below took hold of the hook when it got within reach, and, watching his opportunity when a fishwoman was looking another way, fastened it in the gills of one of her fish, which instantly rose in the air."

It was determined at last to make a sweeping reform of the Scottish prisons, and it was accomplished in 1839 by the act of 2 and 3 Vict., c. 42. The varied and multitudinous bodies, chiefly municipal, which had authority over the prisons were suppressed, and a local board was appointed for each county, to act along with, and to a certain extent under the direction of, a general board for the kingdom. The number of prisons, which amounted to about 170, was speedily reduced to about 70. New prisons were built suited to carry out the separate system, which is in force in every prison in Scotland, with the exception of casual and temporary instances, where sufficient room is not found for it. In strictness and completeness of control, the Scottish system is now nearly as far above as it was formerly below the English; and it may safely, for instance, be held, that in that part of the empire the abuses which were revealed in the jail of Birmingham in 1854 would not have been permitted to occur.

Ireland.

It will readily be supposed that the prisons of Ireland had not advanced beyond those of the other parts of the empire. Legislative improvements in that country generally follow the model set by England; and on this principle an act was passed in 1826 for regulating the prisons of Ireland, 7 Geo. IV., c. 74.

It will be easily seen from the preceding statements, and

Experiments in prison discipline.

is indeed well known to every one, that there are great diversities in the practice of prison discipline, and in the manner in which different prisons are managed, even in this country. It is not the object of this paper to lay down a canon of prison discipline, by setting forth that system which is to be held sound while all others are unsound. It is rather the object to trace the progress which the science has made through the suggestions and experiments of its masters, and to describe the practical character of the discipline which at the present day is sanctioned by the greatest amount of practical authority. We shall most conveniently find our way to the character of this modified system by glancing at some experiments in which extreme systems were tried and found wanting.

The solitary system.

The experiments which for several years have been abundantly made in prison discipline have dealt with three chief elements,—1st, Solitude; 2*d*, Silence; 3*d*, Labour. Other adjuncts, in themselves more important, such as education and the ministrations of religion, are not properly mere elements of discipline, however urgent it may be that the opportunity of captivity may be taken for endeavouring to impart them to those who otherwise are denied participation in such blessings. Solitude and silence have been experimented on separately and in combination. Solitude has, from accident or design, often of course been an aggravation of imprisonment before people thought of such experiments; but solitude, as an element in prison discipline, means solitude carried out towards whole classes of prisoners, however numerous, by arrangements which are costly and troublesome, and are intended to promote good ends. A prison on the solitary system must have a cell for each inmate. This system, which was carried to perfection in America, was also practised in the Gloucester penitentiary towards the end of the eighteenth century. Afterwards it was adopted in the bridewell of Glasgow, but in a modified shape, since the solitaries received moral and religious instruction in their cells. It was in Philadelphia that the system was emphatically developed. The Quaker population in that state succeeded in 1786 in their long struggle for abolishing the punishment of death. All punishments involving corporal violence, such as mutilation and the lash, were abolished at the same time; and in looking round for some passive infliction, which should go as far as possible to supply the place of these abrogated terrors, the enemies of bloodshed and violence fell on the practice of continued solitude without labour, books, or any means of occupation to mind or body. On this principle the Wallnut Street prison was first built with thirty cells. The idea being welcomed as the simple solution of all difficulties in prison discipline, was presently followed in Maryland, Massachusetts, Maine, New Jersey, and Virginia. Whatever imperfections appeared in it were attributed to the limited scale of the experiment, and the Pennsylvanians resolving to give it more scope, built the prisons of Pittsburg and Cherryhill. New York at the same time arranged to carry out the system on a great scale in the renowned penitentiary of Auburn, founded in 1816. It is clear that, however easy it may be, at sufficient cost, in such a place, to isolate the tenant of every cell, yet to render this solitude entire and uninterrupted from day to day, and month to month, is scarcely possible. Though machinery may be made to convey to the prisoner his food, and to remove what it is necessary to remove, it is scarcely possible but that, from some accident, the attendant warder may be for a moment seen or heard. The Americans, however, before allowing doubts to be thrown on their idea, pushed it to its utmost conclusions with a relentless rigour, which in this country would not be tolerated. One who had a favour for it in moderation says,—"A trial of solitary confinement, day and night, without labour, was made at Auburn in the year 1822, for ten months, upon eighty of the most hardened convicts. They were each confined in a cell only 7 feet long, 3½ feet wide, and 7 feet high. They were on no account to be permitted to leave the cell during that long period on any occasion. They had no means of obtaining any change of air, nor opportunities of taking exercise. The most disastrous consequences were naturally the result. Several persons became insane, health was impaired, and life endangered. The discipline of the prison at that period was one of unmixed severity. There was no moral nor religious instruction of any kind communicated within its walls, nor any consolation administered by which the convict was enabled to bear up against the cruelty of this treatment. Nor was a trial of the same description which took place in the state of Maine conducted under more advantageous circumstances. The night-rooms or cells at this prison are literally pits entered from the top by a ladder through an aperture about 2 feet square. The opening is secured by an iron grate used as a trap-door. The only other orifice is one at the bottom about an inch and a half in diameter, for the admission of warm air from underneath. The cells are 8 feet 9 inches long, 4 feet 6 inches wide, and 9 feet 8 inches high. Their gloom is indescribable. The diet during confinement was bread and water only. Thus immured, and without any occupation, it will excite no surprise that a man who had been sentenced to pass seventy days in one of these miserable pits hung himself after four days' imprisonment. Another condemned to sixty days also committed suicide on the twenty-fourth day. It became necessary to remove four others who were unable to endure this cruelty, from the cell to the hospital, repeatedly, before the expiration of their sentences." (Crawford's *Report on the Penitentiaries, United States*, p. 16.) In fact, it was a normal result of this system, that the over-tortured mind found refuge in insanity; and so it came to pass that a body of benevolent Quakers, seeking to abolish bloodshed and violence, had by one simple idea discovered a more efficient and protracted system of torture than the ingenuity of all the tyrants of the world had enabled them to devise.

The silent system.

The other great experiment—the silent system—was also devised by the Americans, who drove it to its utmost conclusions with characteristic zeal. It was adopted at Auburn as a resource against the destructive influence of the solitary system, and was afterwards brought to perfection in the no less renowned penitentiary of Sing-Sing. The principle of absolute solitude was still enforced while the prisoners were in their cells; but they were drafted out into large rooms, where they worked in common. In these, the characteristic feature of the discipline was carried out by their working in total silence, never looking to each other, or making any sign, and never even glancing at a prison officer or a stranger visitor. To see a hundred desperadoes thus pursuing their silent labours under the vigilant inspection of no more than five or six officers, gave the visitor an emphatic notion of the control which discipline is capable of achieving over those who are so little under their own control. If it did no other service, the silent system taught confidence to prison disciplinarians, and made them aware how futile all danger from their wayward subjects might be rendered by method and firmness. It has been maintained, and seems probable, that this system of relentless restraint was little less destructive to the intellect than the absolute solitude it superseded. But it was found accompanied by necessary conditions fatal to its success. The only method of carrying out the discipline was by giving the free use of the whip and the rod not only to the superiors of the prison, but to the humblest discipline officers. Messrs De Beaunont and De Toqueville, who were partial to the arrangement, say in their celebrated Report on the American Penitentiary System,—"At Sing-Sing, the only punishment for those who infringe the established order is that of the whip. The application of this disciplinary means is there very frequent, and the least fault is punished with its application. For various reasons, this punishment is preferred to all others. It effects the immediate submission of the delinquent; his labour is not interrupted a single instant; the chastisement is painful, but not injurious to health; finally, it is believed that no other punishment would produce the same effects." In a note to this passage, the authors say, that "no register is kept of disciplinary punishments." Mr Crawford states that a rule had existed prohibiting the infliction of more than thirty-nine lashes at a time, unless in the presence of an inspector; but the punishment was thus found to lose its prompt efficiency, and the restraint was removed. "The quantity of punishment is entirely dependent on the will of the overseer, against whose acts there is no appeal." The very principle of the establishment, indeed, precluded not only all appeal against it, but all knowledge of the fact that punishment had been inflicted, unless such as the officer inflicting it might think fit to reveal; for it was a crime for a prisoner to speak either to a stranger or an official visitor to the prison. There was thus established in the heart of a republic probably one of the most perfect models of irresponsible power by man over his fellow which the world had known. The nature of such a power may be best judged, not by the abuses charged against it, for no one can tell how much exaggeration there may be in such charges, but by an instance of its moderate and legitimate use. An assistant keeper was charged with cruelty to a pregnant female convict. There was no witness but himself and the convict; and his own statement of the case—a statement on which he was acquitted and retained in his office—was as follows:—"Mr Parks told me to flog her. I then took a cow-skin and went into a room, telling the two blacks to watch, and if she came at me with any dangerous weapon, to defend me. She then went and sat down upon the bed, appearing to me to be somewhat frightened, and told me if I whipped her to death she would not move. Her convict frock was open and large, so as to leave her shoulders bare, it being warm weather; and I struck her about three or four blows on the shoulder, and I think not more, and on the naked skin, and then stopped and admonished her as to her conduct." On receiving from her some abusive language, he says,—"I then gave her three or four strokes with the cow-skin. She sat firm, and seemed determined to brave it out, swearing that she would not submit. I ceased again; and observing that the blows left marks upon her shoulders, and fearing I might break the skin, and as she continued to rave, I struck her a few blows above her knees, and in front, as she sat." The woman's account of her chastisement was of course more formidable. She died, and it was certified on medical authority that the whipping had caused her death. The managers of the institution thought otherwise; and on the man's statemen of the way in which he had used it, retained him in his irresponsible power. They did so apparently for the purpose of maintaining some rigid principle, and the general tendency of the inquiry is to show that they had intentionally deprived themselves, by the rules they had adopted, of the means of ascertaining whether their officer was guilty or innocent. (Crawford's *Report*, 18, 19.)

It is questioned whether the silent system, when carried out with the highest skill and the most implacable rigidity, accomplished its purpose of precluding communications among the prisoners. All who are practically acquainted with prison discipline know that, under repression, the faculties left available—and there will always be some—attain an abnormal power and sensitiveness, as the remaining senses do for the service of those who are blind or deaf. It is almost impossible to anticipate what may be achieved in this way among hundreds of restless creatures all bent on one object. The keepers of prisons, where much more effective means than the silent system have been available for intercepting communications, have remarked, that it seemed as if some supernatural agency were at work in the rapidity with which prisoners make themselves acquainted with facts supposed to be beyond their possible knowledge, and communicate them among all their brethren. The inspectors of prisons on the silent system, approaching however noiselessly, and peeping through an inspection-hole covered with coloured glass into a workshop, would, by a certain flutter in the demeanour of the prisoners, see that their presence there was known; and discoveries were sometimes made which showed a thorough understanding of some concerted plot in the penitentiaries of America. It is understood that in that country the silent system is no longer observed in its integrity. It had its admirers in this country, who, however, had no opportunity of carrying it out with a like rigour. It was long avowedly the system of the Cold-Bath-Fields prison; but this building, containing 1400 prisoners on short sentences, ever coming and going, had in reality little in common with the sepulchral silence of Sing-Sing.

Labour.

This American experiment performed one eminent service. It gave the first emphatic practical testimony to the value of labour as an element in prison discipline. Perhaps the earliest work in which labour is spoken of not as a punishment, but rather as a corrective and resource, is in an Essay on *The Prisons of the Religious Orders*, by Mabillon, a work in which there is an amount of practical sagacity available even for the present day, which it is strange to owe to a Benedictine monk of the seventeenth century, whose chief studies lay in antiquities. (*Ouvrages Posthumes de Mabillon*, iii. 321.) Employment in productive industry stands prominent among the prison reforms both of Howard and Bentham, and it had been practised in the rasp-houses and spin-houses of Holland. Now that it has thoroughly established itself as a fundamental principle of prison discipline, and is in fact almost the only large operative principle about the value of which there are nowhere two opinions, it seems marvellous that the inhabitants of our jails should so long have been driven by forced idleness to spend their time in ribaldry, mendicancy, trickery, mutual corruption, and all available vices. Labour draws the prisoners off from mutual communication when they are associated, and is the best solace and safeguard to the mind against the ravages of solitude. It teaches the criminal, while he is in custody, that lesson of duty and service which he has not learned, or has not practised, in freedom; and if his captivity be long, it may even communicate to him the means of earning his bread by honest industry. Nor, while thus beneficent in its operation, does it tend sensibly to decrease the terrors of imprisonment; for, however much the criminal may feel the blessing of occupation after he is immured, it is not one of the characteristics of his class to look forward to labour as a boon. It is a further though secondary advantage of prison labour, that it economizes the expense of punishment. To make prisoners self-supporting is an object which has been frequently pursued of late, but without much success. It was accomplished, however, in the American penitentiaries under the silent system, and was one of the boasted advantages of assembling the prisoners together in large bodies, where they worked under the discipline of terror. In Belgium it was at one time the practice to farm the produce of prison labour to contractors, who were allowed to hold out inducements to the prisoners to work hard, and thus plied them with spirits and tobacco. When prisoners are kept in separate cells, and the discipline proper to their condition is deemed more important than the value of the work done by them, the produce of their labour never repays more than a small portion of the cost they occasion. This is to be understood of criminals kept within the walls of prisons. Convicts who are undergoing in this country a substitute for the transportation to Australia which used to be their lot, can be gregariously employed in labour of many very effective kinds; but it has hitherto been found most expedient to apply it to docks, harbours, and other public works.

Hard labour: tread-wheel, crank.

The efficiency of labour as an element of prison discipline has sometimes been estimated so highly that it has been deemed all-sufficient for the sole object in view. A criminal, as the case is sometimes put, has incurred a debt to society, which he is bound and should be entitled to work off by the results of his industry. Such a debt would fall upon the debtor with a weight very inadequate to its proper magnitude; for great criminals, who are often very clever men with extensive practical resources, could be rapidly reducing the debt against them, while their stupider and perhaps less guilty neighbours would find the effort entirely hopeless. The established systems of prison discipline in this country, far from admitting the principle, that the prisoner's labour is exacted as a material payment of his debt to society, sometimes exact unproductive labour where that debt is greatest. The application of "hard labour," or unproductive and purely afflictive exertion, is one of the least satisfactory problems in prison discipline. The shape in which it was first practised on a large scale was the tread-mill,—a great cylindrical wheel turned on its axis by the tread of a certain number of prisoners. To this form there was the objection, that it could not be modified to the strength of individual prisoners,—all must take step after step together upon the wheel as it revolves, and bear the infliction, great or little as it might be, of mounting a certain number of steps. A form of hard labour has been introduced in the military prisons, called the shot-drill, consisting in the piling, removal, and re-piling of pyramids of heavy shot. The standard form of hard labour, however, in the ordinary prisons is now the crank. It consists of a small flaked wheel, a little like the paddle-wheel of a steam-vessel, which, as the prisoner turns a handle outside, revolves within a box which is partly filled with gravel. The continuous shovelling up of the gravel, as a paddle-wheel tosses up the water, is the labour performed. The amount of strength necessary to each revolution can be regulated to the utmost nicety by the quantity of gravel raised. An external register records the number of revolutions made, and it is usual to place the register outside the prisoner's cell. Prisoners are not set to this hard labour at the discretion of the prison authorities; they are condemned to it as part of their sentence by the court which tries them. This kind of afflictive labour is not a beneficent element of prison discipline, and many are the plausible arguments launched against it. But it has the stern support of practical effectiveness. It was devised to increase the odiousness of the prison to the criminal, and stimulate his efforts to keep beyond its walls; and, by the testimony of practical men, it has had this good effect.

stablishent of the parate stem.

Founded on the experience of the great experiments just referred to, there came into practice, by a sort of general assent, an arrangement which has been called "the separate system," although in reality it is not so much a system promising positive results from itself, as a practical compromise, keeping clear, on the one hand, of blind negligence, and on the other, of those absolute principles, such as silence and solitude, which were found to be so destructive. The first object of this system is to keep the prisoners from contaminating and criminal communication with each other. From the old jails the youth who had just entered the borders of crime often went forth an accomplished depredator. While the experienced contaminated the young, they planned in the dissolute idleness of the prison-yard, new depredations. Altogether there could be no doubt that, whether or not the terrors of punishment restrained from crime, a residence in a prison generally made a man more vicious. To extinguish at once this cause of deterioration, the separate system provides a cell or room for each prisoner. The arrangement is costly, but its cost must be met by those who think its advantages worthy of being purchased. In his cell the prisoner is supplied with work and books. Since he is not to keep company with his fellows, and yet is not doomed to the horrors of solitude, arrangements must be made for furnishing him with a limited amount of improving society; and this also is costly. His most valuable visitor will be the prison chaplain or the clergyman of his own faith. If there be in the callous bosom of the reprobate any seeds of faith and goodness, the decorous repose of a well-ordered prison, and the judicious admonitions of a zealous minister, will give them their best opportunity for quickening. How much hypocrisy may often be developed on such occasions,—how many times the deceitful heart is reconciled to virtue only so long as the opportunities for vice are distant, are questions it is unprofitable to ask. The opportunity should be given liberally by a proper supply of able and zealous chaplains, though the results must remain in impenetrable secrecy; for to investigate the statistics of penitence and reward professions of reformation, would obviously lead to the grossest acts of deception and hypocrisy. The clergyman's efforts are aided by the teacher, who probably imparts even to the old offender the first rudiments of civilized knowledge. The visits of the physician come at intervals, and the discipline officers are instructed at stated times to enter each cell. More rarely his cell will be entered by the chief of the prison; and at longer intervals a government inspector or a director will visit him. Such are the usual provisions for removing the character of solitude from separate confinement. Besides its influence in obviating contamination, some have sought, in a very rigid rule of separation, so far to isolate prisoners that they shall not be aware of each other's presence under the same roof. It is desirable certainly, that if a man becomes penitent, the full amount of his iniquities should not be known to the companions who are likely to seduce him from reformation; and it is still of far greater moment that the fresh offender, who desires altogether to cancel his connection with the world of crime, should not be seen within the prison walls, and afterwards recognised by the hardened criminal. Whenever it is safe to dispense with this pedantry, as some call it, of the separate system, there are countervailing advantages to the discipline. A considerable quantity of vigorous daily exercise is essential to prisoners under long imprisonment. If they take this exercise wholly unseen by each other, it can only be in narrow yards, where they spend a listless hour; while, if paraded in common on a wider space, life and energy may be communicated to their motions. For worship, and sometimes for instruction, association without communication has many advantages over rigid separation. But these, indeed, are all matters at present under experiment and discussion, and it is difficult to get further, without crossing debateable land, than the general principle, that the old, free, corrupting communication among imprisoned criminals should be suppressed.

Secondary arrangements.

Among minor adjuncts, the cleanliness of modern prisons, though occasionally it may be laughed at, is never directly censured. It is essential to health, and its moral influence is beneficial. At the same time, it is no seductive luxury, for, much as well-conditioned gentlefolks would feel the blessing of a clean, well-ventilated modern cell as a substitute for the filthy dens of last century, the criminal classes are little susceptible to the privilege, and it may be questioned if the cleanness and comfort of the cell awaiting him in prison ever crossed the thoughts of a criminal to reconcile him to his actions. Ventilation, dryness, and an abundant supply of light, are adjuncts of a similar character. Nothing, indeed, is generally more surprising to one accustomed to associate safe custody with massive gloom, than the cheerful lightness of the galleries in a well-built modern prison, and the absence of those features of exaggerated architectural strength which belong to the traditional idea of the castle dungeon. Small prisons, where there is no systematic organization, still depend on their structural strength; but where there is a large staff and many prisoners, the chief reliance is on the discipline; and it is considered wholesome to let prisoners feel that they are not an object of terror, requiring very formidable precautions. The harsh, fierce manner which characterized the turnkey of old is now little known in any well-regulated prison. The officers, in exacting obedience to the daily routine of discipline, should be unimpassioned as fate; and the criminal feels himself all the more helplessly prostrate before the strength of the law, that he is an object neither of fear nor of wrath.

It is scarcely necessary to say that the material means of luxury, intemperance, or sensuality should be absolutely unattainable. To graduate the restraints upon the appetites, however, so as to render all sufferers in the same degree is impossible. The regulation food, for instance, cannot be rendered other than a luxury to some; and, as a general rule, prisoners, after a certain period, gain appetite, enjoy their meals, and improve in physical condition. It is impossible to avoid this unless the dangerous doctrine were admitted, that it is proper to deteriorate their physical condition. The prison dietary is, or should be, adjusted to the lowest quantity of plain food which will preserve the human being in his normal condition. The criminal at large deteriorates this condition by his vices, but within the walls of the prison he is not permitted to do so; and thus the world is sometimes invited to see the ludicrous contrast between a criminal fattening within a prison, while the honest workman, who is only a little careless and dissipated, is wasting under the influence of intemperance, filth, and unwholesome diet, just as the prisoner was before he was committed.

Such are some of the chief characteristics of a well-regulated prison, according to received modern notions. In estimating their efficiency, it must be kept in view that they are, so far as their effects are visible, elements of prison discipline only. They provide for the punishment and for the good conduct of the prisoner. In doing so, they save him from the contamination which he would have caught in a prison under the old system; but nothing is more dangerous than to assume that his conduct in prison is the outward sign of inward regeneration. The most orderly and pliant under good discipline may be, and often is, the most hardened villain within the walls. It is necessary to look this unpleasant truth in the face, and to see in it the proper boundaries of the function of prison discipline; but it is right to remember that close imprisonment is a punishment, among us at least, of comparatively short duration. It seldom reaches, and scarcely ever exceeds, two years. The careful scrutiny to which prisons are now subjected has suggested that the separate system in its most approved shape cannot be long enforced without the deterioration of the prisoner. As will be hereafter told, the greater criminals are now to be subjected to years of training instead of years of transportation, and it remains to be seen whether prison discipline, directed into this new channel, will accomplish new and enlarged effects.

Government of prisons.

Besides the adoption of a sound form of discipline as a standing rule, there are many safeguards and precautions necessary to the government of a prison. It is a place of restraint where men must to some extent be under the absolute authority of their fellow-men. The most elementary knowledge of human nature teaches that the kind of man has not yet been found in this world, who can be trusted with power absolute and uncontrolled over his fellow, and the history of prisons is an emphatic commentary on this text. On the amount and character of the control which shall best exact a due responsibility from prison officers, there have been as many differences of opinion as upon the various methods of discipline. Publicity, so valuable and so largely drawn upon in this country, naturally suggests itself; but there cannot be primary simple publicity in a prison. Though crowds might be admitted within the walls at certain times, they could not be always present, while the prisoner and his master are there at all times of the day and night. Confluences of miscellaneous visitors, indeed, while they woefully disturb the influence of a proper discipline, can see or know scarcely anything of what is really enacting within a prison. The old London prisons, in their worst days, and the prisons on the silent system in America, received visitors freely. The visits of strangers to a prison must of necessity be limited, and instead of a fallacious theory, that all the world are entitled to the privilege, it is better fundamentally to draw a line which shall limit it to the class of persons who are least likely to be enticed by idle curiosity, and most likely to use the opportunity for beneficial purposes.

The most important visitor, however, who can enter a prison is an official inspector who is independent of the rulers of the establishment, while he is entitled to investigate all their proceedings, reporting the results of his inquiries to the supreme government, through whom, in this country, they find their way to Parliament. A large portion of the prisons of the United Kingdom are governed by local bodies of a corporate character, who are under more or less responsibility to the government. The most important of the prisons, however,—those in which convicts are detained,—are, as we shall see directly, under official control. In a country where there is so much parliamentary responsibility, such official control is not considered constitutionally dangerous, and it has great advantages in its efficiency and systematic regularity. Still there are distinct appreciable advantages in a certain amount of prison management being vested in independent men of the country gentleman and retired citizen class, were it merely that they may check the extreme and intolerant development of official theories, and give discussion and ventilation to projects of prison discipline, both before and after they are brought into practice.

Imprisonment for debt.

The practice of imprisonment for debt must not be wholly overlooked in tracing the progress of prison discipline in this country, though the peculiarities which at one time communicated to it a too intense interest have become obsolete. It will be noticed that many of the grossest irregularities and worst cruelties in the British prisons were concentrated in this department. These irregularities and cruelties were characteristic of the early defects in our prison system; of the shyness of control and interference, and the consequent latitude to all persons to inflict or suffer to any extent, provided the infliction and the suffering were according to law. As affording scenes of tyranny, suffering, recklessness, profligacy, and villany, the debtor's prison has been a favourite with English writers of fiction; and those even of the present generation will hand down pictures from this favourite field of study which will doubtless excite the indignation and astonishment of posterity. A revolution has been almost noiselessly made in this department by the re-adjustment of the laws of debtor and creditor. Formerly the creditor was denied access by form of law to the debtor's estate, and he took vengeance on his person; hence the industrious man might be kept idle, separate from the means of supporting his family, or even paying his creditor; and on the other hand the man of fortune might live in jail, spending his money, and defying his creditors to touch his estate. The procedure for realizing and appropriating the property of the debtor has now, however, been rendered more complete and effective. At the same time, the honest and fair debtor can obtain a speedy discharge under one of the bankruptcy or insolvency statutes. It hence arises that those who are now long detained in prison for debt are in some measure criminals as well as debtors, having been guilty of fraud or culpable recklessness. There is thus less reluctance to subject them to the rigid discipline applicable to criminals, with its cleanliness, order, and abstinence. The prison tavern, a fixed characteristic of the old debtors' prison, if it now exists anywhere, must do so in defiance of authorized regulations against it.

iscellaneous unishments.

Having thus followed the practice of simple imprisonment down to the present day, it will be proper to glance at those other forms of punishment which have always been more or less connected with it, in order that we may see more distinctly the sources and character of the mixed form of penal discipline which has lately come into operation in this country. It is obvious that detention within the walls of a prison is a very costly punishment, which a cruel or penurious government will abandon for a readier and cheaper. Afflictive therefore as its practice has been in England, its extensive use there is yet a testimony to the national moderation and clemency. Nowhere else, unless perhaps in Holland, did its use preponderate so much over more violent methods of punishment. Although our criminal code was eminently sanguinary, actual executions were more rare than in most other countries. Excepting banishment and transportation, to which we shall presently come, almost the only other forms of punishment much in use in this country were the stocks and the pillory, which, in addition to a certain amount of painful restraint, subjected the victim to the brutality or spite of the miscellaneous public. The brutalizing tendency of the pillory, the proper sphere of which was generally some public market-place, is at once obvious; and, dependent on the immediate impulses of a mob, it sometimes elicited cruelties which ended in death, and at others was turned into an ovation which reversed the object of the punishment A popular publisher, in George III.'s reign, stood in the pillory with a laced footman on either side attending to his wants, and an obsequious crowd offering him homage. These forms of punishment, along with that of public whipping, have been long disused. Whipping has been lately restored in another form. It is, except in some special cases, only applicable to boys or very young men, and is administered privately in the presence of responsible officers.

The barbarous punishment of mutilation was not quite unknown in Britain, although the occasions for its legal infliction were peculiar and rare. Torture, which was largely used in other countries, was always very offensive to the national feeling, and never established itself as a fixed institution. By far its most extensive use was in examinations of persons charged with witchcraft. Whenever that word was employed, all concerned seemed to be driven by a panic of terror and hatred entirely out of the bounds of reason and humanity, and things were done by people of station and good repute which cannot be excelled by any cruelties on record. Apart from this one blot, it is ever a remembrance of proud satisfaction in this country that, careless as the administration of justice sometimes was, and afflictive in its carelessness, our ancestors would not attempt to perfect it by introducing the horrors of the "question," or probationary torture. The vindication of this infliction has ever been, that the object is to spare life by exciting through torture the certain evidence of a confession. But apart from the numberless instances in which the confession so extorted must have been false, the torture itself, which generally reduced the victim to utter helplessness, was a punishment far worse than death. We may form a notion of what it was, only too painfully distinct, in the celebrated cases of Urban Grandier and the Calas family. Slavery at home is a form of punishment which has ever been inimical to the constitution and habits of this country. Though we have now forced labour in the convict establishments, the form in which this punishment has been carried out among our neighbours, by the convicts working here and there in chains on streets, quays, or other public places, was nearly as offensive to our people as slavery. Among the continental governments, the mines have formed the easiest form of punishing by slavery and forced labour. This, as we have seen, was a method of punishment among the Romans, and it is possible that there are mines in central Europe which have never ceased from their time downwards to receive convicts. There is no kind of place of custody whence escape can be rendered so hopeless, and none so secure from stray inquiries after the fate of those who have been dropped into them, and left there to perish forgotten. The Russian empire has the reputation of possessing in its mines the most terrible places of punishment in the world.

The galleys *bagnes.*

A well-known form of punishment in some European states was the galleys. They were almost peculiar to countries bordering on the Mediterranean, being unsuited for more stormy seas. They were ill-shaped, narrow vessels, with benches for rowers. To these benches the galley-slaves were chained. Fixed to their benches day and night, the state of filth and brutality in which they existed is at once understood; and yet, with the free air around them, their condition was less to be deplored than that of victims of a higher rank, whose privilege it was to occupy dungeons. Galley slavery was introduced into France about the fourteenth century. Its head-quarters were at Marseilles, where there was a renowned fleet of these vessels. France sometimes engaged to take prisoners from other countries into her galleys, which had a high repute, and sometimes portions of the fleet were let for the service of some Mediterranean power. The neighbeuring states on the coast of Africa imitated the happy idea, and kept fleets of galleys manned by Christian captives. In 1748 the galleys were abolished, and the convicts were confined in *bagnes*, which were either buildings or old hulks. There they were, as formerly, chained to a bench; and though sometimes required to work, they were in general left in idleness. The natural taste of the French for ingenious efforts of handicraft was remarkably developed among these men, who made the bagnes of France famous for the quaint toys and *bijouterie* fabricated in them. After the first revolution, the *travaux forcés* were adopted, and the convicts were kept at systematic labour. The removal of the convicts to these depots was both offensive and dangerous. At any great prison, such as the Bicêtre, when a sufficient number of convicts had accumulated to make what was traditionally called a *chiourme*, they were rivetted to a long chain, and sent off to walk to their destination attended by guards: "Woe," says Vidocq, "to the females whom they met, or the shops which they came near. The women were assaulted in the grossest manner, the shops stripped in a twinkling." This method of transit was not abolished until 1836. The Memoirs of Vidocq, the celebrated secret agent of police, give a lively description of the scenes in the prisons of detention, in the passage of the chain, and in the bagnes. If his own attempts to vindicate himself may be discredited, there is no occasion to question the general fidelity of these accounts, which are equally characteristic and horrible. There is nothing too abominable for belief in places where 600 convicts were after their labours herded together in one great hall or apartment, with sentinels around to bar exit, but no attempt at order or discipline within. France subsequently produced many able expositors of prison discipline, and the bagnes were by degrees improved. They were abolished by the present imperial government in 1852; and the system of transportation was adopted in France just as it had virtually come to an end in this country. To those who were already condemned it was thought fair to make transportation an alternative at their choice. Books were opened for volunteers at the bagnes of Rochefort, Brest, and Toulon. The result was the converse of what was lately exhibited in this country when transportees were required to stay at home. A rush was made on the books, and 3000 names instantly adhibited. (Berenger, *De la Répressión Pénale*, i. 378.) It might have suggested itself as a question, whether a mode of punishment which convicts adopted for themselves so zealously would be likely to meet the legitimate purposes of punishment. The French convict settlement is in Guiana.

Origin of transportation from Britain.

Before the date of this experiment Britain was the only modern European power which systematically practised transportation. It was long viewed with distrust, as infringing on an old constitutional rule against inflicting punishments on British subjects beyond the realm,—a rule suggested by the continental possessions of the Plantagenets, and the opportunity which these afforded to the crown of evading the English laws for the protection of the liberty of the subject. An interval elapsed after this danger had passed away before the possession of colonies opened up the means of administering punishment abroad in places over which Parliament and the law had rather more control. Something like transportation is enacted in the celebrated vagrancy statute of 39 Elizabeth. It provides that where the said rogues "shall be dangerous to the inferior sort of people," or shall remain incorrigible "in their roguish kind of life;" after the discipline of the act has been applied to them, they may be committed to jail to await the quarter-sessions, where the justices may ordain that they "be banished out of this realm, and all other the dominions thereof," and "be conveyed into such parts beyond the seas as shall be at any time hereafter for that purpose assigned by the Privy Council unto her Majesty." The earliest known enforcement of this law is attested by a letter of King James I., written in 1619, and addressed to the treasurer and council, commanding them "to send a hundred dissolute persons to Virginia, whom the knight marshall shall deliver to them." (Chalmers' *Pol. An. of America*, p. 46.) The term "transportation" was first used in an act of a similar tenor passed early in the reign of Charles II. It was adapted more systematically to the purposes of punishment by an act of 1718, which authorized the criminal courts in clergyable offences, or those which were nominally but not really punished with death, to give over the offenders to contractors, who engaged to transport them to the American colonies. The contractors were vested with a property in the labour of the convicts, for seven or fourteen years, and this right they sold, generally by auction. These convicts became valuable to the planters in those warm southern states, where the unwillingness of the inhabitants to devote themselves to any kind of toil, and the consequent temptation to exact labour by force, have ever been inimical to the interests of freedom. Hence, before the greater attractions of Negro slave labour were felt, there was much competition for the convicts. Their value, indeed, led not only to stretches of the law, but to an organized system of kidnapping along the British coast. Young lads thus seized and carried off were passed through the ceremonial of an apprenticeship, but the planters were under no responsibility, and virtually these apprentices were white slaves. These practices were suppressed about the middle of the eighteenth century, but the legitimate traffic in convicts continued to be vigorously pursued until the American war of independence closed the market against it. Governor Philip, when employed to find a substitute for it, remarked that "the benefits of this regulation were various. The colonists received by it, at an easy rate, an assistance very necessary, and the mother-country was relieved from the burden of subjects which at home were not only useless but pernicious; besides which the mercantile returns, on this account alone, are reported to have risen in later times to a very considerable amount." This he estimated at L.40,000 a year, being the price of 2000 convicts sold at an average amount of L.20 a head.

America.

Africa.

In looking over the world to find a spot fitted to succeed the American colonies as the receptacle of convicts, the west coast of Africa was the first to attract attention, and a few criminals were actually sent thither. There were many reasons, however, against such a selection; among others, was the insalubrity of the district; and although there were people who thought it no objection to the place chosen for a criminal population that it was one where they might be short-lived, it was for the consideration of these, as well as of others who thought it improper to subject convicts to a form of punishment which might prove capital, that the penal stations were to become important colonies, and should be fitted for the permanent residence of free immigrants. The great island-continent of Australia, newly made known to the world by Captain Cook, was at length adopted for several reasons; among others, because it was remote, it was salubrious, and it was believed to possess undefined elements of wealth, among which a large prosperous community would arise capable of absorbing the criminality of Britain.

Australia.

There probably never was an occasion in which hopes were so fully entertained that the solution of the great difficulty had been found, and crime was on the eve of extermination, as the juncture of commencing transportation in this new shape. And as these hopes were the fruit of much earnest reflection and discussion, they were undoubtedly so far justified that the new system was a vast improvement on the old. When convicts were sent to settled colonies exercising a certain amount of free-will, the convenience and profit of the colonists could alone be consulted. Now the colony was to be made for the purposes of carrying out penal discipline, and the free emigrants who chose to go to it must take it as they found it, and make their convenience subservient to its primary objects. The chief feature in which this difference became at once distinct was that, while the transportees to America were handed absolutely over to individual owners, those sent to Australia were to be put into the hands of a responsible public officer —the governor of the colony.

The new system was officially organized by orders in council dated 6th December 1786, issued under the powers of an act which vested the selection of the proper place in the hands of the king and council. The first fleet, as it was termed, sailed in March 1787 from Plymouth, conveying 600 male and 250 female convicts. There was immediate evidence that, with whatever deliberation the quarter of the globe had been selected, the subsequent proceedings were rash and hasty; for so little preparation was made for the reception of the colony that it had actually to search along the coast for a proper site. It was supposed that Botany Bay, of the fertility of which there had been a glowing description, was to receive the new convict colony; but the governor, Captain Philip, found a better site within the heights of Port Jackson, where he founded the town of Sydney.

Early history.

It appeared to be supposed that, going to a fruitful country, the convicts would soon be able to provide for themselves. They were accompanied by a staff of agricultural superintendents, who were to direct them in the cropping and general management of the land, as if they were a body of agricultural labourers entering on possession of a few established farms at home. But it was found that the convicts could not do farm labour if it had been duly set to their hands; and that the agricultural superintendents could not have rendered Australian land available if their hands had been the best farm labourers in England. It was of course deemed necessary to provision the colonists until they could raise food for themselves; but so imperfectly was this accomplished, that a famine placed them, from the governor downwards, on starvation allowance, and only the prudent firmness of the governor kept them from extirpation until the arrival of a second fleet with convicts and stores brought temporary relief. A large portion of this second detachment died by the way; and it was said that this mortality, by lessening the number to be fed, saved so many lives on shore which must otherwise have yielded to privation. Of the general condition, moral and material, of the infant colony, the select committee on transportation in 1838 afford the following brief description:—"The community was composed of the very dregs of society,—of men proved by experience to be unfit to be at large in any society, and who were sent from the British jails, and turned loose to mix with one another in the desert, together with a few task-masters who were to set them to work in the open wilderness, and with the military who were to keep them from revolt. The consequences of this strange assemblage were vice, immorality, frightful disease, hunger, dreadful mortality among the settlers; the convicts were decimated by pestilence on the voyage, and again decimated by famine on their arrival; and the most hideous cruelty was practised towards the unfortunate natives. Such is the early history of New South Wales."

It was maintained at the time that this new form of transportation created a lively terror among the criminal population. Little was known about the actual fate of the ship-loads of convicts despatched from time to time, until Colonel Collins published his account of the colony in 1804, but the little that transpired was a history of calamity. No element as yet appeared in the arrangement attractive to the minds of criminals. The mysterious disappearance of their friends into a distant wilderness raised appalling prognostications, which were aggravated by an opinion current among the favourers of the scheme, that somehow or other it would be found that those who were sent out would never return, and that this indeed was the most hopeful feature of the scheme.

Encouragements to onvicts.

It was not intended, however, in the formation of the new colony, that the convicts should continue to be dropped on the barren shore of a wilderness. There was to be a mixed colony, of which the convicts were to be a portion; and in the further stages of the experiment we have to look to the position of the criminals, as affected by that of the free colonists. But while it was contemplated that the convicts should form merely one element in a miscellaneous settlement, all the primary preparations were made for them alone. The first step in free colonization was taken in the year 1791, when the governor made three grants of land to free settlers, giving at the same time one grant to an emancipated convict. For some years grants of land were given occasionally to free settlers or to emancipated convicts, or emancipists, as they were termed. There was no rule of preference, and the distribution appears to have depended on the immediate expediency, in the eyes of the governor for the time being, of making or withholding grants. The placing of the convict in a position in which he could hold property by emancipating him, was in the same arbitrary position,—depending on immediate circumstances and personal opinions or predelictions. Writers who have entered on the local politics of the colony have severely criticised the grounds or motives on which classes of the population or particular persons were encouraged or discouraged. Without entering into these discussions, it is sufficient to note them among other indications, that from the beginning there was no effort to mark distinctly the condition of the transported offenders. It became known that many of them had suffered hardships which rendered their sentence a cruel and protracted death; it was soon afterwards known that some of them were comfortable landed proprietors, and that others were making fortunes. In the year 1810 Governor Macquarie, who was charged with increasing the encouragement given by his predecessors to convicts, appointed an emancipist named Andrew Thomson to the magistracy. He vindicated this action on the ground that he intended in an emphatic manner to restore the man to respectability because he had earned it by his good conduct; but on the other hand, it has been maintained that the man was made a magistrate merely because he was active, clever, and successful.[1] Soon afterwards, three emancipists, backed by a recommendation from the governor, applied to the supreme court for license to act before it as attorneys. The application was strenuously resisted by Mr Bent, the head of the court, who was presently afterwards recalled by the home government. Thus, in the earlier stages of the system, the convict was either a captive in the hands of the government, who kept him in imprisonment, or at most allowed him the limited freedom of a bondsman employed in public works; or, when there was any relaxation of this condition, the convict might be in the way to make his fortune or to become eminent and influential.

The assignment system.

In the meantime, however, the influx of free settlers operated as a relief, by creating a middle stage, and rendering it no longer necessary that the convict should be either a prisoner or a landed proprietor. The system of the assignment of convicts to the free settlers commenced. At first it was necessary to bribe them with privileges to take convicts off the hands of government; but as the several Australian colonies increased, there came to be a competition for assigned convicts, rising in eagerness according to the order of their usefulness. This was a restoration of the American system, but with a large difference. The assignee held the convicts, not in his own right, but as representing the government, and under the conditions imposed by the government. Among these there was a restraint on corporal punishment, which could only be inflicted by a magistrate. The punishments for offences against discipline were severe, and were very readily inflicted by a magistrate on the master's statement; but often the distance from the magistracy nullified the right to punish, and the only hold on the convict was the risk of his being sent to one of the penal settlements, where the irreclaimable, or, more properly speaking, those who could not keep control over their vicious propensities, were kept under strict and severe discipline. The assignee, in fact, did not, like the American purchaser, obtain an actual property in the person of the convict, which he might dispose of by sale or let out on hire.

It happened that the peculiar nature of the Australian lands afforded, for a long time, facilities for advantageously working assignment as a medium of penal discipline, such as no other tract on the face of the globe, except perhaps some portions of Russia and Northern Germany, could have afforded. The available parts of the country were covered with a natural pasture, very thin, but valuable from its vast extent. It took five acres to feed a sheep; but countless millions of acres were obtainable. This gave the greatest facilities for slave labour—that is to say, it gave, to the utmost extent, those conditions in which a mere human being, existing and placed upon the spot, is of value, independently of his expending industry or ingenuity. Not only were many shepherds and neatherds required to take charge of the stock on these pastures, but a still humbler class, called hut-keepers, were employed in numbers, to keep watch in the remote grazing-grounds. The convicts assigned to this function lived far apart from each other, and at great distances from all resorts of man. Thus they could not be spreading contamination or concocting crime, unless they deserted and became bush-rangers. Their luxuries were tea and tobacco; of the great incentive under which most of them had become vicious, ardent liquors, they had none, from the difficulty of taking such a commodity so far inland. It is said that under no possible circumstances could liquor be conveyed to the distant stations, because, the carriers being convicts, and excessively addicted to drinking, no concealment could elude their vigilance, and no bribe or punishment would induce them to spare the liquor committed to their keeping. But as the colonies increased in population and affluence, other less beneficial sources of assignment opened. Among these was domestic service, almost the only means, indeed, which offered for the disposal of the female convicts. There arose by degrees considerable industrial establishments, engaged in building, mining, shipping, and curing the fat and skins produced in the grazing districts. In these it was of great moment to have skilled workmen, clerks, and book-keepers. The practice in the assignment of convicts was, that on a convict vessel being reported to the governor, they were removed respectively to the male barracks or a female penitentiary, where the superintendent of convicts classified them according to their several occupations and capabilities. They were then apportioned out according to the privileges, and, as far as these were consistent with each other, the wishes of the settlers. It was naturally a great prize to a man embarked in a difficult and lucrative business to find, as he sometimes might, a clever criminal trained to it. To the full services of such a person, when assigned to him, he was of course entitled; nor would he be bound to pay for these services more than rations, and other allowances settled by regulation. But there is no such thing as skilful and valuable labour extracted through pure slavery. Though nominally a slave, some of the rewards of this kind of labour must go to the worker before he will give it forth. The expert housebreaker, and the receiver of stolen goods who might have caused the criminality of hundreds of thoughtless young people—the forger, long steeped in guilt—could be very useful, and give valuable service, which did not go without its reward. The poacher, transported for assault—the workman, who, in hard times or under the tyranny of a strike, had yielded to temptation, suffered the hardships and privations of transportation, while he saw these greater criminals rolling in luxury. Worse still: the honest, hard-working mechanic, who had emigrated from inability to combat with the difficulties at home, sometimes found that his own lot was little improved by the change, but saw the country seat and the well-kept carriage of some great notorious offender, and wrote home to his friends an account of what he saw. In the curious autobiography of Hardy Vaux, a London thief of great ability, who had been twice transported to New South Wales, it appears that through his abilities and plausibility he made himself very comfortable there; and from his description of the state of society, it is clear that any clever and expert criminal, if able in some measure to restrain the indulgence of his vicious propensities, could convert his punishment into a means of enjoyment and success. The Parliamentary Report already cited, referring to frauds of an oppressive and cruel kind effected by wealthy emancipists, states that "the instruments were drawn up by convicts; for in those days amongst that class only could persons be found qualified to perform the duties of the legal profession." A state of society, in which emancipist capitalists transacted their business through convict lawyers, is perhaps sufficiently suggestive of triumphant vice; but there are plain broad statements as to the condition of the convict colonies in the same report, a specimen at least of which should be recorded. Thus, among the evils of the assignment system are enumerated—"*First*, The assignment of convicts to their wives or other relations that have followed them to the colony with the proceeds of the offences for which they were transported, and upon which they have set up a profitable business, have become wealthy, and thus have held out to their acquaintances in this country strong temptations to pursue a similar career of crime. *Second*, The employment of convicts as clerks to the various departments of government, where they have had means of acquiring knowledge, of which the most corrupt and dangerous use has been made. *Third*, The employment of convicts as clerks to attorneys, with free access to the gaols, which has given rise in the colony to an unparalleled system of bribery and connivance at crime: at one time even the clerk of the attorney-general was a convict, and performed all the legal business of his master. And *lastly*, The entrusting to convicts of the education of youth in the various public seminaries."

---

Discipline and punishments of the transportees.

Amid the evils spread by such a system among the free settlers, it is clear that little could be carried on in the shape either of the punishment or the reformation of the convicts. This is but one side, however, of the picture; the other represents the convict amenable to what must have been heavy punishment, if punishment can be entirely measured by the amount of pain, misery, and degradation caused by it. Of the convicts left with the government, or returned on their hands as useless or incorrigible, a large number were employed on public works, chiefly in the making of roads, the first public requisite of a colony. Generally desperate men in considerable bands, they were under strict military control. They were divided into two classes,—those who were in chain gangs, and those who were not. Of the former, the committee of 1838 say,—"They are locked up from sunset to sunrise in the caravans or boxes used for this description of persons, which hold from 20 to 28 men, but in which the whole number can neither stand upright nor sit down at the same time (except with their legs at right angles to their bodies), and which, in some instances, do not allow more than 18 inches in width for each individual to lie down upon on the bare boards; they are kept to work under a strict military guard during the day, and liable to suffer flagellation for trifling offences, such as an exhibition of obstinacy, insolence, and the like; being in chains, discipline is more easily preserved among them, and escape more easily prevented than among the road parties out of chains." If it were asked why a method of superintendence so barbarous and cruel was adopted, the answer would be found partly anticipated in the concluding clause of the quotation. In a community where all were so bad, those above the average in wickedness could not be kept under the necessary inspection and restraint unless by force and terror.

These chain bands, however, only consisted of what might be called, in relation to the whole tribe of convicts, the inferior class; there was a stage of penal discipline still further on for the criminals—for those who were to the convicts at large what these had been to the ordinary run of the home population. Their punishment was accomplished by a second transportation to what were called the penal settlements: one, for the less aggravated cases, was at Moreton Bay; another was the rocky and wooded island of Norfolk; a third, for the Van Diemen's Land convicts, was Port Arthur, a sterile peninsula, reached by a narrow strip of land, on either side of which were chained a row of ferocious dogs. All who were practically acquainted with them seem to have had difficulty in expressing what they felt of the horrors of these penal settlements. A convict quaintly said of them: "Let a man be what he will when he comes here, he is soon as bad as the rest: a man's heart is taken from him, and there is given to him the heart of a beast." The reckless despair that came over these men was shown in the fact, frequently attested, that they would commit murders on their keepers or their companions for no better motive than the excitement of the deed and the subsequent journey to the gallows, as a variation of the uniform misery of their lot, or for the simple purpose of earning release by the punishment of death. No force or vigilance could prevent them from making desperate efforts to escape. The Report of 1838 says of a return of the attempts to escape from Macquarie harbour, a penal station then abandoned: "From that return it appears that, of 116 who absconded, 75 are supposed to have perished in the woods; 1 was hanged for murdering and eating his companion; 2 were shot by the military; 8 are known to have been murdered, and 6 eaten by their companions; 24 escaped to the settled districts, 13 of whom were hanged for bush-ranging and 10 for murder;—making a total of 101 out of 114 who came to an untimely fate." At the end of the Report there is a narrative, taken from the survivor, of the escape and wanderings of one group of fugitives, describing with horrible minuteness the manner in which one after another was killed and eaten, until two remained watching each other with hungry and murderous eyes for days, until the opportunity came for one to strike his exhausted companion.

Demoralization.

But terrible as such a picture is, it does not exhaust—it does not even reach—the deepest shades of Australian convict brutality. There were found to have spread practices more dehumanizing than cannibalism itself. It was long obvious that, in communities where bands of men were herded together, no vigilance or coercion could prevent some dire results; and although those who were the first to face the difficulties of the question by an inquiry into facts, must beforehand have anticipated with certainty some revolting details, yet it may safely be said that they were, in the midst of their inquiry, appalled both by the systematic extent and application of the evil, and the depth to which it had driven its roots through the colonial community. Those who did face the difficulty were the committee of 1838 already referred to; and though they were necessarily brief in their statements, it is clear that the tenor of their recommendations was founded on the knowledge not only that transportation, according to the system then pursued, must be abolished, but that no statesman, aware of the facts known to them, would ever re-establish it, unless some new form in which it could be effected—a form radically free of these terrible evils—could be found. What rendered this, however, the less probable was, that although coercion drove the convicts to occasional violence, the crimes, which were the stamp of their deep degradation, prevailed, wherever the discipline was relaxed—wherever, in short, they were not rendered impracticable. It was during the attempt of a well-meaning man, who was permitted for a time to try "the law of kindness" on the conduct of the convicts in one of the penal settlements, that their degraded habits were most conspicuously developed: these were found to have been deepening and expanding under an external varnish of contentment and improvement. The tighter the hand of the law was held over the convict, the better he was.

icket-of-eave ystem.

To modify the licentiousness of the increasing band of emancipists, the ticket-of-leave system was invented. In place of an absolute pardon, the convict obtained a ticket or license to be at large under certain restrictions, and to work on his own account. It could be earned only by good behaviour, and was revocable for misconduct. It could be obtained after four years by a convict transported for seven; after six years where the sentence was for fourteen; and at the end of eight years when it was for life. Thus, in some measure, the government got rid of the heavy charge of the convicts during part of the long periods of their sentences, and the convicts themselves had advantages to look forward to and to realize; while, on the other hand, a wholesome restraint was kept over them for a long time after punishment had ceased. The conduct of the ticket-of-leave men was found to be good in comparison with that of the emancipists; but that the extent of coercion to which they were subjected made them so, was one of the disheartening features of transportation. In the Report of 1838 it is said,—"On the whole, it appears from the evidence taken before your committee, that assigned convicts conduct themselves better than ticket-of-leave men, and ticket-of-leave men than emancipists or expirees; and that, when transportation does produce orderly conduct, it does so by imposing restraint, and by the apprehension it produces of immediate and severe punishment. The orderliness of a convict increases, therefore, with the immediateness and severity of the punishment, and with the general restraint to which he is subjected, and at the same time decreases with the decrease of temptation. Thus a convict is best behaved while at the penal settlements, and his conduct deteriorates in proportion as he obtains more and more freedom, and is worst when he has obtained liberty by the expiration of his sentence."

Re-action against transportation.

These were conditions not conformable with the intended object of transportation. If it could only act through coercion and control, there was no occasion for seeking these agencies so far away from home. When the Australian transportation was expected to supply the place of the American on an increased scale and in an improved shape, it was believed that the criminals would be absorbed into the free colonial population. In reality the convict element predominated, and gave its mark to the condition of the Australian colonies; and that, although a larger free colonial population had arisen, from incidental causes, than the founders of the colony had contemplated. The convict connection—consisting of emancipists, ticket-of-leave holders, and emigrant families which had or formed connections with these classes—were strong enough to make a party, and sometimes strong enough to bear down the free settler interest. It was natural that principles not only loose but depraved should triumph with them. Those who had the immediate charge of the convicts—soldiers and civilians—almost became brutalized down to their level, and fit companions for them when they had earned their leave. In the families of decent emigrants there were horrible revelations of the corruption of the young from the employment of convict domestics. A local party at length arose whose bond of union was the extinction of transportation. It was joined by many wealthy colonists, and was gradually swollen by a large influx of middle-class emigrants. Another contemporary influx of a humbler class promised to buy out transportation, by rendering the convicts worthless as labourers. By the peculiar arrangements for disposing of the land in Australia, a portion of the considerable price paid for it was reserved as a fund for assisting working men to emigrate. Those obtained were not all well suited to their purpose: peasants of a docile, patient kind were wanted, where restless, clever, discontented mechanics were obtained; but on the whole they were more valuable than convicts. These ceased, from the rapid enlargement of the demand for labour, to be numerically important. It was announced in 1838 that the number of fresh labourers wanted was 10,000, and the number of convicts received in the ensuing year would be but 3000. Many of the squatters were still favourable to transportation, as a means of easily supplying them with the slave labour they desired. These, however, once the supreme aristocracy of the country, were declining in influence, from bad seasons and the preponderating influence of other interests.

A conviction in the meantime arose at home that transportation was a wasteful and ineffective punishment. The well-weighed Report of the select committee of the House of Commons, already referred to, repeating, on the foundation of a close inquiry, defects which Bentham had anticipated thirty years earlier, strengthened this conviction. The committee, after showing how this punishment might, from arbitrary accidents quite independent of the guilt of the convict, oscillate through every conceivable grade, from sufferings beyond the endurance of the human frame at one extremity, to affluent prosperity at the other, made the following suggestive remarks:—"Exile is least dreaded by the most numerous class of offenders,—by those who may be termed habitual criminals, and who compose what is properly called the criminal population of this country,—namely, regular thieves, pickpockets, burglars, and all persons who gain their livelihood by the repetition of offences, and who consequently have lost all feelings of moral aversion to crime, and can only be restrained by fear. The apprehension which this class of offenders feel for the punishment of exile amounts merely to an aversion to breaking off their criminal habits and connections in this country; on the other hand, to them the consequences of abstaining from a life of crime would be, that they must equally separate themselves from their friends and associates of the criminal class in this country, and lead a life of honest industry in a country where wages are low and the price of food is high. To such criminals this course of life must seem almost as disagreeable as, if not more disagreeable than, the chance of exile to Australia, where they understand that wages are high, and that their condition will be a comfortable one; that at all events they will obtain plenty of food and clothing, and that they will meet a number of ancient companions in crime, some of them in the most prosperous circumstances. Consequently among such individuals, especially among London thieves and the like, the threat of expatriation produces little or no motive to induce them to abstain from criminal acts."

Gradual abandonment of transportation.

In the year 1840 it was found expedient to suspend the transmission of convicts to New South Wales. The system of convict punishment was soon afterwards revised, with a view of bringing the number transported down to a proportion with the limited field for their absorption. It was resolved that the convicts, before being removed to a colony, should be subjected to preliminary discipline at home. When Pentonville prison was opened in 1842, the secretary of state, Sir James Graham, explained in a state paper that it was intended in that establishment to subject convicts to a system of penal discipline, which should not only be in itself a punishment in as far as it was a long imprisonment, but would train them so as to render them better fitted for their fate in a penal colony. They were to be detained eighteen months in Pentonville, and then drafted off to the penal colony most suitable to their disposition and condition. It was soon found, however, that the eighteen months' detention would not reduce the number of convicts so far as to enable the remainder to be absorbed by the transportation fields, which were yearly narrowing. Accordingly, it was resolved to give a second stage of the convict's sentence to labour in public works, and then to transfer him to the modified restraint of a penal colony. Such works were found at Gibraltar and Bermuda; and in 1846 it was resolved to create the great convict establishment connected with the Portland quarries and breakwater. Having first undergone a long imprisonment, and then a still longer discipline in the public works, the convict was to become an exile, subsisting on the fruit of his own labour in a penal colony, which he could not leave without rendering himself liable to the punishment of a returned convict. Events at the Antipodes, however, defeated even this modified use of the old transportation fields. The governor of Van Diemen's Land—the only convict colony which still remained open—informed the home government that the ticket-of-leave and conditional-pardon men were there competing with the free labourers for a scanty subsistence, and that the colony would be overrun with paupers, the greater portion of whom were also criminals. It was useless to send to such a place men whose chance of restoration to virtue depended on their finding ready and lucrative employment. Hence, from the beginning of the year 1848, the transmission of convicts to Van Diemen's Land ceased. Thus had the seemingly inexhaustible resources of the great Australian world for the absorption of our criminal population collapsed with an embarrassing degree of suddenness. Some further efforts were made ere it was entirely abandoned. A new settlement for convicts was projected and nominally established in Northern Australia, but for many sufficient reasons it was abandoned. In 1849 it was proposed to land some convicts, who had undergone their probation in prison and public works, in Australia. The squatting interest, having a lingering partiality for convict labour, would have welcomed their arrival, but the indignant remonstrances of the rest of the inhabitants were effectual to prevent a landing. The opening of the gold diggings immediately afterwards rendered the whole region the most unsuitable place in the world for the reception of convicts in any stage of their discipline. An attempt was made to use the settlements in Southern Africa as a convict station, but it was effectually resisted. The isolated colony of Western Australia continued to receive a small number of exiles, but it now became clear that, in the meantime at least, provision must be made for detaining our worst criminals at home. Besides women, the government had then about 6000 male convicts, ever increasing, on their hands, and the task of disposing of them was serious. The first difficulty was to meet the fact, that the sentences of this large number of persons ordained them to be conveyed beyond seas, a judgment which could not be carried out.

Penal servitude.

To provide against the further accumulation of such sentences, the first Penal Servitude Act was passed in 1853, substituting for the old sentences of transportation sentences to the new denomination of punishment for much shorter periods. This act was in itself a standing admission that the government, if it required the transportees to take out their sentences at home, must in good faith materially abbreviate them. Each transportee, when sentenced, knew that though the period of his bondage was nominally seven or ten or fifteen years, yet, if he conducted himself well, the greater portion of it would be spent in the comparative freedom of simple exile. The only practicable arrangement was to remit a large portion of the sentences. The reception of this adjustment afforded curious evidence of the charms of transportation to the criminal world. The men received it with sullen discontent and remonstrances about breach of faith. The effect of the disappointment among the female convicts at Millbank was, as the directors reported, to make them, "without reason or provocation, suddenly break into acts amounting to frenzy,—smashing their windows, tearing up their clothes, destroying every useful article within their reach; generally yelling, shouting, and singing as if they were maniacs."

Home tickets of leave.

In the arrangement for abbreviating those transportation sentences, it was deemed prudent that the government should not altogether relinquish the hold it had over the criminal through the original duration of his sentence. Accordingly it was resolved that the remission should be conditional on good behaviour. When the time for the convict's release came, he received, not a free pardon, but a license to be at large, from the secretary of state. The ticket, which he carried with him as a certificate of this license, informed him that it would be withdrawn, and he would be subjected to endure his original sentence, not merely if he lapsed into crime, but if he led a questionable dissolute life and kept low company. The men thus released, called ticket-of-leave men, created a renowned panic in the years 1854 and 1855. The public would not look at the fact, that the license was intended for their protection—that the men must have been releassd, since it was impossible to send them abroad in terms of their original sentences—and that the release was rendered conditional, that a control might be had over their motions. The public dwelt with morbid panic on every separate crime committed throughout the country, asserting that it was perpetrated by the hands of ticket-of-leave men, whom the government had designedly let loose upon the world. On one point the suspicions of the public had a plausible foundation. It was seen that the secretary of state was not in the practice of withdrawing the license when the convict had fallen into evil repute, unless he had actually been committing new crimes. In fact, the secretary of state felt, when he came to the practical exercise of the power vested in him, that it was questionable in a constitutional view, and disliked to take on himself the responsibility of visiting men with a heavy punishment on the ground of their mere repute, and of the opinion formed of them by police-officers.

Abolition of transportation sentences.

The result of this public clamour was a very valuable parliamentary inquiry into the whole condition of the convict question. People could not see that it was impracticable, over the whole face of the globe, to have a new convict colony, and it was well to exhaust that question by practical inquiry. It was exhausted. Every man who had a scheme to propose for the absorption of our convicts abroad was invited to explain it. The result was, that no one could point to a colony, or to any other foreign community, where the convicts could be absorbed into society as they used to be in America, and were to some extent in Australia. On the other hand, it was easy to find places suited for convict stations; that is to say, places where great prisons could be built, and convict labour carried on either within the prison or in the open air. But it was not necessary that establishments like these should be placed at the Antipodes. On the contrary, the nearer they were to the centre of government, the more strict would be the control over them, and the more effective their moral influence over the criminal population of the country, who would know them to be real places of punishment, cleared of the atmosphere of attractive dubiety which is apt to surround far-off penal settlements.

In consequence of this inquiry, the act of 1857 was passed, abolishing sentences of transportation, and substituting for it, in all cases, sentences of penal servitude. What penal servitude is has never been defined, unless it be a definition of it to say that the penal serf is a public slave in the hands of the secretary of state for the home department. It may be carried into effect either at home or abroad, and is capable at any time, shonld the means become available, of being rendered the same thing as transportation. It varies from periods of three years to the whole period of life.

Arrangements for home discipline.

It will be seen that, although transportation to the Australian colonies came to an abrupt and unexpected conclusion, yet a concourse of circumstances had been gradually diminishing its extent, and opportunity had been given for finding a proper substitute. Thus for some time those chiefly concerned have had before them the weighty problem, how far the progress of the science of prison discipline is possessed of resources to meet the new burden thrown upon it. The country was clearly in a better position to meet the difficulty than on the former occasion, when America was closed. The prospect of having to throw the convict population on the resources of our prisons, such as they were in those days, was appalling. But the progress which had been made was, as has been already stated, strictly in the discipline of persons sentenced to limited periods of close imprisonment, and it remained to be seen how much of the science thus acquired would be available for longer periods of detention.

In this view, the effect of the discipline in the model penitentiary at Pentonville was closely watched, and the conclusion adopted was, that the separate system, however suitable it might be for carrying out the usual fixed periods of imprisonment immediately followed by release, could not to any good purpose be continued for the established periods of transportation or penal servitude. Pentonville was at first peopled by prisoners selected for their health and strength, and at the healthiest age, who were kept there for a limited period until they should be sent abroad. But as the transportation fields narrowed, it was found necessary to open the prison to all classes of convicts, and they were kept there for considerable periods, uncertain as to their future fate, and apprehensive in many instances that they would have to endure the whole period of their sentences in monotonous isolation. They became visibly deteriorated both in body and mind, and the number who lapsed into insanity became alarming, not only for the sake of themselves, but from the indication so afforded that a much larger number, who had not reached the length of insanity, were likely to be more or less mentally deteriorated. The visiting physician, Dr Owen Rees, in his report for September 1850, having observed that five cases of mania and eight of mental delusion had occurred in nine months, said that "these numbers would appear to render it probable that some cause for the production and development of insanity is in operation in the prison which did not formerly exist. This consideration, induced by the statistics of the prison, would not, however, urge itself so forcibly on the attention were it not that, in my inspections of the men, made from time to time, I had observed an irritability and discontent indicative of a mental condition very different to that shown by prisoners in former years; and, in more cases than I ever recollect before, a despondency and want of mental tone requiring the attention and calling for the anxiety of the medical officer." Another question at the same time suggested itself,—How far the separate confinement fitted the prisoners to go back into society with improved chances of well-doing? and this too reached no satisfactory conclusion. The obedience, docility, and general conformity with the discipline of the prison, which entitled a prisoner to the approval of his officers, were no test of his capacity for self-control. It was even found that the ready compliance which made an inoffensive captive, made a thoughtless, facile member of society, liable to be immediately seduced into his old practices when he found his old associates. It was perceptible that, when convicts were taken immediately from a long course of separate confinement to be associated in public works, they had lost part of the activity and capacity of self-management which is possessed by the humblest class of free workmen, and must be exhibited by them when they have to co-operate with each other in labour. Increased attention to diet, free air, and exercise, in some degree modified these injurious influences. Some convicts at Pentonville were set to garden-work avowedly as a relief to the monotony of the cell. A more comprehensive and effectual remedy was found in active exercise by walking round a considerable area, an arrangement which of course was so far an infringement on the rule of strict separation. It was at last, however, resolved to limit the period during which convicts were to be kept separate. A year was at first the limit fixed, but in 1854 it was reduced to nine months for males; the deteriorating influences being observed not to commence their work on women so readily, it was considered safe to subject them to the otherwise wholesome system of separation for a year.

This limitation only affected the class usually called convicts, and criminals sentenced to imprisonment might have to endure their whole sentence of a year, or even two years, in separation. But it was held that the same deteriorating influence does not follow from the discipline when the whole punishment comes to an early conclusion, and that it was the prospect of a long continuance of punishment, uncertain in its nature and repressive of hopefulness, that made the separation tell so early on the convicts. It is proper to state that neither the policy of the limitation nor the sanitary opinions on which it has been founded have escaped dispute. No one questions that any system which deteriorates the prisoner either in body or mind is unjustifiable, but the deterioration has been questioned. In America it has been maintained that men who had been kept years in a cell without ever breathing the open air, as all prisoners confined for any considerable period in Britain do, had not deteriorated; and that, without associating them with each other, there are many sanitary influences available for the protection of their health. Those who thus believe it unnecessary, condemn the association as subversive of the good effects of previous separation, and a pernicious example to other prisoners, who know that the greater criminals nominally sentenced to higher punishments are in the enjoyment of privileges denied to themselves. Sir John Kincaid, after more than ten years' experience as a government inspector of prisons, says, when reporting on male convicts detained in the prison of Wakefield in Yorkshire, and on the female convicts of Scotland—"It appears to me that, so long as they are in separate confinement, and under the beneficial influences that are brought to bear upon them, they are generally contented, industrious, and, such of them as are endowed with minds capable of reflection, appear to be in a fair way of adopting an amended course of life; but when the time arrives for their being entitled to association, they are but a short time in it when they generally become more idly disposed, discontented, and excitable, showing that vices have been called into active operation which their previous separate confinement had tended to subdue or to eradicate. I am not prepared to say that prisoners sentenced to long periods of imprisonment may not require association; I am only showing the results of it after nine months' separate confinement. I am of opinion, in which I am supported by others well qualified to judge, that a prisoner in ordinary health will not break down on a two years' imprisonment in a suitable separate cell, provided he is allowed a fair amount of relaxation in air and exercise." The chairman of the English convict board, who is in a great measure the author of the new arrangements, says in his report for the same year—"It may, however, be doubted whether the period of nine months, to which the course of discipline is now restricted, is sufficient for deriving the full benefits which attend its enforcement for twelve or fifteen months, which were the usual periods some years ago. Though other causes have been more obvious in relation to the falling-off in point of good conduct which has been noticed during the last two or three years, I believe that the less due preparation for being brought into association has had its share. An important period for reflection and instruction has thus been lost, and I should be glad, when circumstances permit, to see twelve months *again established* as the average period of detention in separate confinement." There is no doubt that the true medium applicable to this branch of convict discipline will soon be indisputably adjusted through a series of cautiously-tried and carefully-watched experiments, remote alike from the cruel carelessness of the old practice or the audacious impiricism which succeeded it.

So far, then, the substitute in a system of discipline at home for the punishment of transportation to the antipodes has been supplied by the system of discipline applicable to the criminals punished by imprisonment at home. It is now necessary to give a general idea of those totally new arrangements which have been adopted for carrying out the remainder of the convicts' sentence. It will be unnecessary to state chronologically the changes made in these arrangements, because they were at first influenced by the supposition that a portion of the convicts' sentence was still to be passed in a penal colony. It was seen at last, however, that even the sole remaining convict settlement, Western Australia, was unlikely to find room for the 600 which it was estimated to receive; while the number of convicts sentenced in the United Kingdom in each year amounts to more than 3000. Hence it was necessary to adjust the stages of discipline so that they could all be carried into effect at home. To meet this great difficulty, a new method of administration was adopted for England, where the bulk of the British convicts are kept. The convict prisons of Millbank, Pentonville, and Parkhurst had been managed by separate boards, each consisting of several statesmen and other men of eminence acting gratuitously. These were abolished in 1850, and the whole administration of the convict department was vested in a board of three official commissioners, appointed by, and responsible to, the secretary of state for the home department. Colonel Sir Joshua Jebb, who had long acted as surveyor-general of the English prisons, was appointed chairman of the board. Thus it fell to his lot to have the chief influence in the organization of the new system, and by his official position, as well as his zeal and ability, he may be said to hold the leadership of the practice of prison discipline in this country.

It was considered that the period of separation allotted to the convict as the first stage of his sentence would serve a double purpose. It would be in itself a heavy punishment, deterrent to evil-doers, and it would render the untamed human being amenable to order and discipline, and more manageable during the subsequent stages. The object of these stages is, by mixing other elements with that of punishment, gradually to adapt the convict for the life of a useful and, if possible, a religious and moral citizen; and if this should not be even to any extent accomplished, then at all events, to keep him alike from doing mischief to society and from deteriorating under the influence of prison life. As in the separate system itself, the most material ameliorating engine in this operation is labour. The kinds of work which can be conducted in a separate cell are limited and not very productive. A great deal of the labour in separate confinement is, as we have seen, intended to be afflictive only, and entirely unproductive in the economic sense. The convicts' labours have the greatest practical amount of productiveness in view. Being no longer conducted in solitude, they have the economic advantage of division of process, and at the same time they fit the men better for the real industrial pursuits of life, by far the greater portion of all hand labour being conducted in combination, as in the instance of the mason, the carpenter, the plasterer, the worker in metals, and the manufacturer of most of the textile fabrics.

The country being prosperous, there was less than might have been expected of the outcry which such projects have usually to endure about the hardships to the honest workman, who has to encounter the competition of the felon. To the general economic influence of this objection there is the conclusive general answer, that were the felons behaving as all good men desire they should behave, they would themselves be honest, industrious workmen, competing with their brethren, and reducing their wages, were it true that the increase of the number of producers, and consequently of consumers, does decrease the rate of wages. There could be no such general answer to the specific objection, that government, bringing the large capital invested in convict management into the market, might unduly press on particular crafts, especially the smaller and less powerful. But it was easy, practically, to meet the objection by avoiding underselling, and by a discreet selection of classes of produce, and of markets, in which the trade driven by the convict establishments would be too trifling to be felt. At the same time, there were many obvious advantages in sending the great bulk of the convict labour into channels where it would cause no competition with free labour. In this view, convict labour has been devoted to the executing of public works, which, though eminently valuable to the country, might not have been undertaken but for the opportunity thus afforded; and waste land has been reclaimed, adding a certain average to the fertile soil of the country, which would not have been added to it as a remunerative speculation, and consequently would not have given employment to free labourers.

Public works.

The industrial disposal of convicts has been greatly aided by the works undertaken on Portland Isle, in consequence of the recommendation of a commission on harbours of refuge, "that a breakwater be constructed in Portland Bay, sheltering an area of 1200 acres." Subsequently fortifications were added to the breakwater and the harbour-works. The peninsula itself supplies the oolite rock so well known as Portland stone for these works. Hence a quantity of labour of various kinds has been concentrated within one narrow corner to an extent rarely exemplified. It is the nature of the oolite beds to require before the very fine grained, compact building-stone is excavated, the removal of masses of rough unequal stone. This, useless for other purposes, is dropped into the sea as the material of the great breakwater. There is thus a long gradation of labour, from the roughest and the hardest that is undergone by the most ignorant excavating navvy, up to the finest masonry, and the other operations necessary for the finishing of the fortifications and harbour-works. From the report for 1858 it appears that on the breakwater there had been executed work to the value of L.31,836, being at the rate of L.34 a man. On the fortifications the work was valued at L.3165, 11s., or L.31, 9s. per man. On the prison edifice masons and labourers did work set down at the rate of L.25, 12s. 8d. per man. Others working in-doors, as tailors, shoemakers, cooks, and bakers, were estimated to have done work worth L.21, 12s. 2d. each overhead. The greater part of this labour cannot undergo the market test; and it can only be taken for granted that the Convict Board have accurately estimated it according to the methods with which employers of constructive labour are familiar. It used to be estimated that the average value of the work of a convict in the hulks was about 2d. a day. That the labour, while increasing so much in efficiency, has also increased in its penal influence, may be inferred from the following remarks by Mr Dobie, the chaplain of the establishment:—"I think the working of the large quarries to provide stone for the breakwater meets the incorrigible offender by visiting him with very severe toil, and for such men scarcely anything could be more effectually deterring than this hard and incessant labour. The execration with which the idle have regarded this compulsory toil presents the Portland prison as an important agent of terror to repress crime. Many men, on leaving, do not hesitate to admit that before they committed the crime which brought them hither, they had no notion that they should be subjected to so severe a yoke; and they have often added that they should warn their old companions of their experience of some two or three painful years." Slave labour is naturally meagre in results; and that labour should be exacted, not only productive, but oppressive, at once suggests that some operative cause, other than pure force, must have been at work. Its nature will be explained further on. At Portsmouth there is another convict establishment where the labour is to some extent similar. According to the governor's report for 1858, it consists, "in the dockyard, of coaling and ballasting ships of war, unloading colliers, removing and stacking timber, attending ship-wrights, &c.; in the Royal Clarence victualling-yard, of loading and unloading vessels, stowing casks, cleaning tanks, &c.; and about Haslar hospital, principally in works of an ornamental character." In the navy department convicts were employed "in scraping shot and shell, and performing various useful services in the gun wharf." "Calculating the value of the labour performed by actual measurement, or where measurement has been impossible, then by approximation," he sets it down as L.28,392, or L.32, 8s. per convict. At Chatham a new prison, superseding the hulks, has been opened for above a thousand convicts; and it is stated that "their labour will be devoted to the extensive new docks, and other works which are proposed to the eastward of the present dockyard." It will readily be seen that these establishments afford a wide range of industrial occupation. The government, at the same time, hire vacant accommodation in county prisons, as at Leicester jail, and the house of correction at Wakefield in which there are usually about 400 convicts.

It is of course important that when a criminal has acquired any skilled occupation, it should not be wasted to the public, or deteriorated to himself, by his being set to the rough drudgery which the untrained can perform better. With the resources, however, at the command of the convict department, it will rarely happen that a man possesses mechanical skill which cannot be used. Overseers, clerks, and the few educated and professional men who find their way into the convict population, can to a considerable extent be set to appropriate occupation, chiefly in the details of the extensive businesses conducted by the convict department. In prisons where extensive works are conducted, there is the same economic advantage as in free workshops and manufactories, in the organization of the labour not being disturbed by the employment of the sick and aged, who may at the same time be fit for other and lighter work. The official staff who superintend the able-bodied convicts, cannot also do justice to the condition and claims of the disabled. Accordingly, the permanently diseased, the superannuated, and those overtaken by the premature old age brought on by the excesses, the privations, and the excitements of the felon's life, are provided for in separate prisons. One of these is the new prison of Working, which has been or is nearly completed: the inmates destined for it were removed from the hulks to a temporary prison at Lewes. The other establishment for this class of prisoners is on the breezy heights of Dartmoor, where they are to a great extent occupied in reclaiming waste land and in farming. The governor, in his last report, lamenting the death of an intelligent farm-bailiff, says, "this zealous and faithful public servant has, by his unceasing energy and great practical skill, produced inconceivable changes on this barren spot, rendering that which only a few years since presented a most sterile and forbidding character, now worthy of being compared with Devon's finest and most luxuriant farms." Convict boys are sent to the prison of Parkhurst, in the Isle of Wight. The chief occupation of the prisoners there is agriculture, but some are trained as masons, sawyers, carpenters, painters, tailors, shoemakers, and brickmakers. By a special statutory provision, the secretary of state sends boys sentenced to long imprisonment, as well as convicts, to this prison; and it is very suggestive, that the officers of the establishment, for the credit of their system of discipline, deem it necessary to draw a broad line of distinction between the conduct and general condition of the convicts whom they have for several years, and those whom, as undergoing sentence of imprisonment, they can operate on only for a period comparatively brief.

Inducements to exertion.

Such is a general view of the occupations of the male convicts in England. It will readily be felt that, if a healthy development of productive labour, accompanied by that good conduct which is its necessary attendant, has been brought about by mere force, the phenomenon is new in the moral history of mankind. The stimulus of reward, and the still stronger stimulus of hope, have, however, accompanied the coercion. The rewarding of malefactors, or the mitigation of their sufferings, as the return for good conduct in prison, is not a novelty. Difficulties, however, have always been felt in the method and extent of the application of the principle. If carried far, so as materially to affect the character and extent of a sentence, then it follows that the awarding of punishment, which is jealously restricted to judges bound by acts of Parliament, who pronounce their sentences under the highest responsibilities in the face of the public, would be shared by the administrators of prisons, whose functions are performed in privacy, and who would naturally act on such evidence or other operative inducement as might suit their own views and wishes. True, the rulers of the prison could only alter the sentence of the judge in the direction of mitigation; but even the discretionary possession of this power might indirectly be turned to the increase of severity, for the existence of such a power might be contemplated by the bench, and the prisoner might be sentenced to a punishment reducible by his future good conduct, while the reduction might be justly earned, and yet withheld. These considerations must always hamper the practical adoption of schemes, of which there are not a few, for adjusting the criminal's fate, to his conduct and the character he has acquired, after he has been convicted.

Wherever there is danger of discretionary power being abused, there is at least a partial corrective in a record of the circumstances which give a ground for the exercise of the power. A hasty or vindictive discipline officer, presuming him to be invested, without control, with the right of mitigating or increasing a criminal's punishment, would be checked in the unjust or cruel exercise of his power by the necessity of keeping a record of the events and circumstances which lead to its exercise. The merit of having invented such a record, in "the mark system," appears to be due to Captain Maconochie. This gentleman has suggested a bold and original scheme of prison discipline, of which, as it has not, save in one feature, met with practical acceptance, a criticism would, on the present occasion, be out of place. It may simply be remarked, that those connected with the practical application of discipline have, whether rightly or wrongly, felt that he proposes to appeal to motives, too refined and too closely resembling those by which only men of superior intellect and goodness are led, to be effective upon those coarse natures which have been led into crime by their signal deficiency in the very springs of action to which he appeals. His method, however, of recording the claims of prisoners by the mark system is now extensively applied. It can be carried out either by debiting the marks for misconduct, or by crediting them for good conduct. In either case, the character recorded to the prisoner is a fund on which he is entitled to draw. A certain number of marks gained within a fixed period entitle the convict to the privileges of a class or grade, which may be certified by a badge such as a sergeant's stripes. The rank so achieved is liable to be forfeited by misconduct.

It is the nature of criminals to be influenced by immediate results, and to be careless of remote consequences. In the loss of a step in a graduated scale, the consequences of misconduct are brought home with immediate emphasis. They are often brought home by immediate consequences; and this leads to the nature of the fund on which the convict's claims, as established by the mark system, enable him to draw. While he is in separation, the conditions under which he will be relieved from the dreary monotony of his confinement, to enjoy a limited converse with his fellows, may be made a powerful instrument of discipline; and so may the possibility of his losing this privilege after he has gained it. Other relaxations will follow. Pursuits giving interest and a modified excitement to the prison life may be to a certain extent introduced. Great influence may be exercised in adjusting the nature and the amount of labour required of him. Their food is generally an object of intense interest and anxiety to prisoners, and when they are actively employed, especially in the open air, they enjoy it with a relish to which they have been utter strangers in their outside life of dissipation. Even within a very limited gradation in the luxuriousness of their diet, and without the admission of any stimulants, a large range of reward and punishment can be reached. Another method of reward is the crediting of certain sums of money or gratuities, at stated intervals, forming a fund for the benefit of the convict on his release.

The most potent of all rewards, however, is release. It is the only one which, even at a distance, is strong enough to stimulate the prisoner in his immediate actions and conduct. But the largeness of the reward renders it one difficult to deal with. It has been seen already that an abbreviation of the sentences of certain convicts, rendered necessary by a concourse of circumstances, created great unpopularity under the name of the ticket-of-leave system, and was productive of considerable embarrassment. This occasion, however, afforded a valuable opportunity for testing, under close and skilful observation, the efficiency of the practice of abbreviating sentences as a means of influence and control over the convicts. After their first disappointment in the loss of the prospect of removal to Australia, the opportunity of earning a shortened sentence influenced their conduct, and gave an impulse to their industry. The act of 1853, which introduced sentences of penal servitude, made the duration of these much shorter than sentences of transportation, with the view of making the new punishment, which was to be endured at home, as nearly as possible equivalent to the removal abroad. It was determined at the same time by the executive authorities, that these shorter sentences should run their course, and that the punishment of the criminal, as pronounced from the bench, should not be subsequently altered except for some special cause. The proceedings of the Convict Board, and the reports made by their officers, show that they felt this rule materially to abridge their influence in training the men to good conduct and industry. In their last report, referring to the year 1855, when the numbers committed under the new form of sentence began to bear a considerable and noticeable proportion of the whole, they state that the change in the feeling and bearing of the men bore some resemblance to the old characteristics of the hulks, their object being to get through their time, and go away with "thank you for nothing," as they expressed it. In Portland prison it is stated that in the autumn of 1855, "a bad and insubordinate feeling was displayed by a number of men under the new sentence of penal servitude: these combined to strike work, assigning as a reason, that they were disappointed as to their periods of imprisonment; and stating that when tried, and in some instances since trial, they had been led to expect that, by good conduct, they would get part of their sentence remitted."

After the act of 1857, abolishing the name of transportation, and recasting the punishment of convicts in periods of penal servitude, the principle of remitting part of the sentence for good behaviour was re-adopted by the government. Care, however, was taken to leave no undue room for a discretionary exercise of the power. A scale of remissions was adjusted in proportion to the different lengths of the sentences, fixing the period to be deducted from each, in case of certified good conduct. For instance, the convict whose sentence was for five years, if he behaved well, was entitled to release after four years, and the convict sentenced to seven years after six. The scale of abbreviations, with an explanatory statement, was transmitted by the secretary of state to all the judges, who, in pronouncing their sentences, knew, and, if they thought proper, may have informed the convicts, that the sentence extended to a certain period, should their conduct while enduring it be pronounced bad, but that if they earned a good character it became a shorter sentence.

Female convicts.

These brief notices of convict organization refer to the establishments for male convicts; but the discipline of convict women has, with some differences, followed the same course. Criminal women are fewer than criminal men, but they are more difficult to deal with. They are inapt to follow the sombre routine of discipline, and where they are collected in considerable numbers there are always a few of them in chronic rebellion against the laws of the prison, to which male prisoners of the deepest dye of guilt are giving implicit obedience. Even while some opening in the Australian colonies seemed to remain for the male convicts there was none for the female, and it was necessary some years ago to look in the face the alternative of detaining them in this country. The mark system and appropriate stages of discipline have been applied to them, but it is difficult to give them an equivalent for what the organization of the male convicts derives from public works. To bring them a stage nearer to the condition of free persons than they can be brought in the prison, an establishment has been formed at Fulham for their reception, after they have passed through Millbank and the female prison of Brixton. It is called "The Refuge," and its chief peculiarity is, that its resemblance to an ordinary prison is as small as the necessary security admits of. The convicts being selected for their good behaviour, advanced to enjoyments which may be forfeited by misconduct, and approaching the conclusion of their sentences, require comparatively little restraint, and enjoy a corresponding freedom within the walls.

Scotland.

It is perhaps propitious to the progress of the important science of their discipline, that the convicts throughout the United Kingdom are not under one administration, but that opportunity may be given for testing the success of different methods of management, each conducted with a close observation of the others. The male convicts of Scotland are removed to England, but no women have been removed from Scotland since the summer of 1855, and those who have since accumulated have been under the management of the General Board of Prisons. They now amount to about 300. The system of advancement from stage to stage has been adopted towards them, so far as the limited accommodation at the disposal of the board has permitted; and new buildings, planned with a special view to their discipline, have just been completed as additions to the general prison at Perth.

Ireland.

In Ireland the convicts, both male and female, are under the administration of the directors of convict prisons there, a board established in 1854. They have several prisons,—Montjoy (with a male and female department), Phillipston, Grange-Gorman, and Spike Island where men are employed as at Portland, in fortification and harbour-works. They have made and put to use moveable iron prisons, which can be shifted to suit the occupation of the inmates in the improvement of land and public works. The arrangement resembles the old road gangs in Australia, and not least in the convicts sleeping in one apartment, an arrangement avoided in all other places of convict custody. The Irish system of convict discipline has followed the English in general, but has gone further in the direction of relaxation, bringing the convicts nearer to the condition of free citizens. They are entertained with lectures and other intellectual and educational relaxations. They are permitted, too, after an advanced stage and evidence of continued good conduct, to pursue occupations beyond the bounds of the prison establishments, and are entrusted with messages and commissions in which they have to account for pecuniary transactions. The directors are very confident in the success of their method, and it will no doubt be fairly tested. The nature and habits of the people are different from those of the British, and the same methods of discipline may not suit both. Indeed, the adaptation of discipline to local and social peculiarities opens some of the most difficult problems of the science. In the instructive book of M. Berenger these difficulties are illustrated with reference to the varied population of France, where the degraded thief, and the Corsican assassin who is yet a gentleman and looks upon his honour as unsullied, have to be imprisoned under the same roof.

Prospects from new arrangements.

Every one who has paid even small attention to the distribution of the penal population from twenty to thirty years ago, when one portion of them were kept at home in ill-managed prisons, and another portion were hustled off to the opposite side of the world, will at once perceive how great is the change operated by late arrangements. Of the improvements in simple prison discipline we have the experience of several years. That there have been advantages in the improvement admits of no doubt; but they do not fulfil in many respects, the hope of sanguine philanthropists. Whoever obtains the opinions of the most intelligent officers connected with criminal administration, will find in them a settled conviction that there is at least one class, forming a large proportion of the criminality of this country,—the hardened professional thieves,—on whom prison discipline has had scarcely any reformatory effect, however much its terrors may have restrained them. The system of long isolation under training, which has but recently begun, and is an entire novelty in penal practice, has to prove its own results, and it would be premature to come to a conclusion on its efficacy. But it is easy to believe that four, six, or ten years, or more if necessary, devoted to suitable training, may produce effects to which imprisonments for like numbers of months were totally inadequate. It will be curious to see the influence of habit on the thief or swindler who has been compelled, during a long period of years, to turn his hand to productive industry. If there be elements of change in himself, there will be perhaps as much in the conditions by which he is surrounded. The criminal classes are ephemeral, growing prematurely old, and dropping out of their social circle from various causes after a brief career; so that when the convict returns to society after a long detention, he will find a new generation at work, who have opened new departments of criminal business with which he is not immediately familiar.

Discharged convicts.

For such discharged convicts as are desirous to do well, the chances that they may find a clear path towards the means of living by honest industry form an anxious problem, not yet solved, to the authorities on prison discipline. There is a strong and natural dislike to them in the minds both of employers and fellow-workmen. Efforts to relieve them from the consequences of this feeling on the other hand are apt to incur the reproach of favouring the criminal above the honest labourer. In Ireland, it appears that convicts are not disliked as labourers, while the police look after them; but the habits of the rest of the empire revolt against this as a form of *espionage*, and the expirees specially looked after by the authorities would have less chance of employment than those left unwatched. The employment of expirees in establishments supported by the government has been spoken of, but rejected, as such assemblages of men, who at least *were* hardened offenders, would be a dangerous pressure on their resolutions to improve, and would afford them both the temptation and the means to relapse into crime. Among the French the system of patronage,—that is to say, of private persons who are wealthy and benevolent taking individual expirees in hand, and watchfully assisting them to gain an honest living,—has been recommended as the strongest available remedy for the evil in the meantime. A few societies having the same objects in view have sprung up in this country, such as the London Reformatory, the Elizabeth Fry, and the Discharged Prisoners' Aid Society. In some of these institutions the expirees are admitted for a time as to a place of refuge, whence they can look about and secure a safe retreat from destitution and crime at home or abroad; while others merely give council and pecuniary aid to enable them to commence their reformed life.

Reformatories for the young.

After the reformatory spirit in prison discipline had for years operated on the criminal population generally, and been to some measure wasted upon old offenders, it lately took a more hopeful direction by concentrating itself upon the young. When *a man* has been caught stealing, the chance is, that he is an irreclaimable thief; but *a boy* caught stealing may yet be trained to honesty. The usual material out of which the old confirmed thief is made, is the child trained in crime by the necessities of an abandoned infancy. Thrown upon the streets as orphans or the neglected offspring of dissolute parents, children find that they must live. Mendicancy and crime are the only means of achieving this object, and there are plenty to teach them these businesses. The more the child possesses industrial energy, the more actively and intelligently will he push his profession, and the more formidable a depredator will he become. It is in this way that the great family of crime is kept up. The parents are in prison or in the convict establishments while their children are learning their hereditary trade. Perhaps the parents may not have reached the sphere of systematic crime, but drunkenness, idleness, and general viciousness have gradually crept upon them, poisoning the sources of the domestic affections, and deadening the sense of duty; and so the next generation, entering early on professional crime, brings the race at last down to the grade of criminality. It has been shown by experience that such children, even if they have begun their career of vice, are not confirmed criminals; and if they are early enough taken in hand, the energies which they would have directed to plunder may be turned to productive industry.

If the adoption in different parts of the world of the same idea, without those who have started it receiving hints from each other, or knowing each other's proceedings, be evidence that the idea is true and just, the principle of juvenile reformatories has such a sanction. It has been adopted and carried out in many places, under the notion that it was quite original, though such institutions were flourishing elsewhere. How old they may be it would be now difficult to tell. The principle in some measure influenced the men who from time to time bequeathed fortunes to found great hospitals; but it is a sort of law of political economy, that what is thus vested to remain for perpetuity ceases to be available for destitution, whatever might be the founder's intention, and becomes a sort of property in the hands of the managers, who give its benefits to those having influence to obtain them. An institution for the really destitute must be under the watchful eye of those who contribute to or are taxed for it. The first reformatory proper, which has received much notice, was founded about the year 1813 by Johannes Falk, a native of Dantzic, whose heart is said to have been opened to the condition of the street children by the loss of four of his own within a few days. His establishment was avowedly a refuge for criminal children and the children of criminals. Several other small establishments of the same kind followed this in different parts of Germany, more than one "saving institution," as they were called, being promoted by Count Adalbert van der Recke-Vollmarstein. In 1824 a larger establishment, the "Society for the Education of Children Morally Neglected," was founded at Berlin. The Prussian government afterwards took the matter up, and several reformatories of different kinds, but all having more or less the training, support, and education of children of the destitute and criminal classes in view, were established under government auspices. In the meantime the principle had made great progress in the United States. In 1823 it was reported by the Society for the Prevention of Pauperism in New York, "that it is highly expedient that a house of refuge for juvenile delinquents should, as soon as practicable, be established in the immediate vicinity of New York;" and in 1826 the state legislature passed an act "for incorporating the Society for the Reformation of Juvenile Delinquents in the city of New York." This was followed by several others; and the Refuges became an important feature in the United States. They are not merely places of voluntary refuge, but children can be committed to them; a practice which was not adopted without considerable hesitation and objection, applied especially to the instances where children not charged with specific crimes were removed from their parents. (See Lieber's translation of De Beaumont and De Toqueville's *Penitentiary System.*) The French had for some time established a distinction between adult and juvenile offenders, those under sixteen being considered as unfit objects of punishment, from having acted without discretion. After various minor efforts in the same direction, the Reformatory of Metrai for criminal boys, was established in the year 1840, by M. Demetz, who has worthily earned a high reputation by the skilful organization and great success of the institution.

In Britain there was a peculiar call for institutions of this kind, because even the reforms in prison discipline pressed it harder on the young. The jail was improved, but it was improved for criminals. The old bridewells and houses of correction did perhaps little for the reformation of their inmates, but they were considered as distinct from the felon's jail,—as places rather for the disorderly and the mendicant than for thorough criminals,—and committal thither did not involve the same infamy as imprisonment within the walls which, now under improved and uniform management, inclose all classes of the committed. The reformatory system had a small and peculiar beginning. The earliest noticed symptoms of its commencement were a humble school in London, and a rather larger one in Aberdeen, where the destitute children of the streets were induced to take education by at the same time receiving food. The example spread and became fashionable, ragged schools, as they were at first termed, quickly following each other. It became soon a serious consideration what was to become of their inmates at the termination of their attendance, when they might go forth with perhaps a smattering of education, and good moral and religious principles, but destitute of the means of self-support. The English poor-law commissioners had observed that when an untrained pauper boy was, according to the old practice, apprenticed off with a fee to a common weaver or other unskilled workman, he usually came back on the parish as a pauper adult; and they promulgated, and to some extent practised, the principle, that a training in skilled labour is necessary to keep a destitute boy from pauperism. This principle was rigidly acted on in the united industrial school of Edinburgh, where it was held better that a small number should be returned productive members to society, than a larger number merely supported and occupied in unskilled pursuits; and the example has been extensively followed elsewhere.

The industrial schools saved from their fate the children who were likely to reach the prison through the commission of crime; the next step was to make them supersede the prison by receiving juvenile criminals. To accomplish this end, it was necessary to make them places of coercion, where the inmates could be legally detained for the proper period. The first step in reformatory school legislation was Mr Dunlop's act of 1854, authorizing magistrates in Scotland to commit vagrant children, whose parents do not find security for their good conduct, to certified reformatory schools. This was immediately followed by Lord Palmerston's act, applicable both to England and Scotland, which authorized the removal to reformatory schools, for periods varying from two to five years, of young people under sixteen convicted of crimes and sentenced to short imprisonments. A marked distinction was thus from the first established between two classes of reformatories—the one for the protection of destitute children likely to commit crime, the other for the punishment, followed by a course of reformatory discipline, of those who have actually committed offences. (J. H. B.)

PRISREND, or PERSERIN, a town of European Turkey, capital of a sanjak of the same name in Albania, on the right bank of the Rieka, an affluent of the White Drin, 82 miles E. of Scutari, and 92 N.E. of Durazzo. It is fortified; and on a neighbouring hill stands a castle, where the Turkish governor resides. Prisrend is the seat of a Roman Catholic bishop. Fire-arms are manufactured here, and are highly prized. A considerable trade is carried on as well with the surrounding regions of Albania as with Rumelia and Servia. Large fairs are held here annually in November. Pop. 8000.

PRISTINA, a fortified town of European Turkey, in Servia, at the southern extremity of the fertile plain of Cossova, 92 miles E.N.E. of Scutari, and 152 N.W. of Salonika. It is the seat of a pasha, and of a Greek bishop, and has several mosques, bazaars, baths, and other buildings. Pop. 12,000.

PRITZWALK, a town of Prussia, in the province of Brandenburg, and circle of Potsdam, on the Domnitz, 66 miles N.W. of Berlin. It is surrounded by walls, and entered by three gates. Woollen and linen fabrics are manufactured here. Pop. 4811.

PRIVAS, a town of France, capital of the department of Ardèche, stands in the midst of barren and rugged hills, on a steep ridge separating the valley of the Ouvèze from that of a small affluent, 26 miles S.W. of Valence. It has one principal street, running along the ridge, and terminating at either end in terraces planted with trees. Though presenting an imposing appearance from a distance, Privas is smaller than the capital of any other department in France; and the only conspicuous building is the courthouse, which has a Grecian portico. In the town and its vicinity there are many mills for reeling and throwing silk, which is produced in abundance in the surrounding country. There are also manufactures of woollen stuff, brandy, and leather; and an active trade is carried on in these articles, as well as in cattle and rural produce. In the civil wars of the sixteenth and seventeenth centuries in France, Privas, which was then a strongly-fortified town, played a conspicuous part, being always favourable to the Protestant party. In 1612 a synod of the Reformed churches in France was held here. In 1629 it was bravely defended by a small garrison under St André de Montbrun against Louis XIII., but after a siege of two months, had to be abandoned. Montbrun, being soon after taken, was hanged; and the fortifications of Privas were levelled to the ground. Pop. (1856) 4804.

PRIVATEER, a private ship of war, fitted out and provided with military stores by a private individual; and the persons engaged are permitted to retain their captures instead of pay, allowing the admiral his share. Privateers may not attempt anything against the laws of nations; as to assault an enemy in a port or haven under the protection of any prince or republic, whether he be friend, ally, or neutral.

PRIVITZ, or PRIVIDIA, a town of Hungary, in the county of Lower Neutra and government of Pressburg, 23 miles W.N.W. of Neusohl. It has a church, Piarist college, grammar school, and manufactures of cloth. There is some trade in corn. Pop. 4730.

PRIVY COUNCIL (*i.e.*, *Secret Council*), as at present constituted, is an assembly of natural-born subjects of Great Britain, unlimited in number, appointed by the will of the sovereign, on whose nomination, after taking the prescribed oath, the appointment is completed. The dissolution of the Privy Council, or the dismissal of an individual member,—as of the erasure of his name from the council-book by the sovereign,—depends upon the Queen's pleasure. The duration of the council is naturally during the life of the sovereign; but it is now continued for six months further, by 6 Anne, c. 7, unless dissolved by the successor. The present usage is for every privy councillor in one reign to be re-sworn at the commencement of the next. From the original twelve members who for centuries managed the most delicate state affairs, the Privy Council was afterwards inconveniently increased. Charles II. attempted to limit it to thirty members; but it was found too divided and too extensive for an effective state council, and was soon abandoned. The Privy Council now generally includes the members of the royal family, the archbishops of Canterbury and York, the Bishop of London, the great officers of state, the lord chancellor, and the judges of the courts of equity, the chief justices of the courts of common law, the ecclesiastical and admiralty judges, and the judge advocate; since 1843 some of the puisne judges to assist in the business of the judicial committee; also the speaker of the House of Commons, the ambassadors, with many of the ministers plenipotentiary and some of the governors of the principal colonies, the commander-in-chief, the master-general of the ordnance, the first lord, with usually a junior lord, of the Admiralty, and the members of the cabinet. There are likewise several offices with which a seat in the Privy Council is conferred,—as the vice-president of the Board of Trade, the paymaster of the forces, and the newly-created offices of president of the Poor-Law Board and president of the Board of Health. There is in no case either salary or emolument attached to the office.

The duty of a privy councillor, as defined by the oath, is to advise according to his best discretion for the Queen's honour and the public good; to keep the Queen's council secret; to avoid corruption; to help and strengthen that which shall be resolved; to withstand attempts to the contrary; and to do all that a true counsellor should for his sovereign. Some of the royal family are not sworn; they are merely introduced.

A considerable proportion of the business of the Privy Council is transacted by committees of council, such as the *Cabinet Council*, the *Judicial Committee*, the *Board of Quarantine*, the *Court of Claims*, the *Board of Trade*, the *Judicial Committee of Council*, and the *Committee of Council on Education*. Meetings of the council are held at intervals of three or four weeks at her Majesty's residence, when her Majesty is attended by her ministers and the officers of state. What is done by the Privy Council when the Queen is personally present, are said to be "acts of the Queen in council." The council collectively is styled "Her Majesty's most Honourable Privy Council;" and the members individually are entitled to the prefix of "Right Honourable." They rank next after the knights of the Garter; and on taking out his *dedimus*, the privy councillor has the right of acting as a magistrate of any county. (See Murray's *Official Hand-Book;* and Warren's Blackstone's *Commentaries*, c. xxi.)

PROBABILITY.

The doctrine of probability is an extensive and very important branch of mathematical science, the object of which is to reduce to calculation the reasons which we have for believing or expecting any contingent event, or for assenting to any conclusion which is not necessarily true. When it is considered that the whole edifice of human science, with the exception of a few self-evident truths, such as the axioms of geometry, is nothing more than an assemblage of propositions which can only be pronounced to be more or less probable, the importance of a calculus which enables us to appreciate exactly the degree of probability existing in each case, will be readily understood.

Our reasons for judging an event to be probable or improbable, are derived from two distinct sources; first, an *a priori* knowledge of the causes or circumstances which determine its occurrence; and, secondly, when the causes are unknown, experience of what has already happened in the same circumstances, or in circumstances apparently similar. Suppose, for example, a hundred white balls to be placed in an urn along with fifty black balls, and that a person, blindfold, proceeds to draw a ball, there is to us, who are acquainted with the contents of the urn, a determinate probability that the ball which is drawn will be white. The balls being supposed to be all in precisely the same circumstances with respect to facility of drawing, we assume that there is the same chance of drawing any one ball as of drawing any other; and, consequently, since there are two white balls for each black ball, and therefore two chances of drawing one of the first colour for each chance of drawing one of the second, we conclude the event which consists in the drawing of a white ball to be twice as probable as the opposite event, or the drawing of a black ball. In this case our knowledge of the contents of the urn enables us to judge of the probable result of the drawing. Suppose, however, that antecedently to the drawing, we were entirely ignorant of the contents of the urn, but that after a great number of trials have been made, (the ball drawn being always replaced in the urn after each trial, in order that the circumstances may be the same in all the trials) it has been observed that a white ball has been drawn twice as often as a black ball, we presume that the urn contains twice as many white as black balls, and consequently affords twice as many chances of drawing a white ball as of drawing a black; and this presumption becomes stronger in proportion to the number of instances included in the observation. In this case experience makes up for the want of *a priori* knowledge, and affords a measure of the probability of the result of a future trial.

It is only in a comparatively small number of cases that all the possible ways in which an event may happen are known *a priori*, and in which, consequently, the ratio of the number of chances favouring the event to the whole number of existing chances is determinate. In fact, most of the questions of this class to which the calculus can be applied, are connected with lotteries and games of hazard. The results obtained from the analysis of such questions cannot be considered as being of any great value in themselves, but they frequently throw light on subjects of far higher importance which present analogous combinations. It is true that the mathematical theory comes in aid of moral considerations, and demonstrates the ruinous tendency of gambling even when the conditions of the play are equal, mathematically speaking; but, unfortunately, those who indulge a passion for this vice are seldom capable of appreciating the force of such arguments. The principal advantage which has resulted from the application of analysis to games of chance is the extension and improvement of the calculus to which it has led.

The calculation of the probabilities of events, the chances of which are not known *a priori*, but inferred from experience, is founded on the presumed constancy of the laws of nature, in obedience to which events depending on constant though unknown causes, are always reproduced in the same order when considered in large numbers. Among the various phenomena of the physical and moral world, nothing is more remarkable than the constancy which is observed to prevail in the recurrence of events of the same kind. The ratio of male to female births furnishes a noted instance. If we consider only a small number of births, nothing can be more uncertain than the result; but taking a very large number, as those of a whole kingdom in the course of a year. the proportion of males to females is found to be almost invariable, and nearly as 21 to 20. The mean duration of human life affords another familiar example. Notwithstanding the proverbial uncertainty of life, the differences of constitutions, and the various accidents to which mankind are exposed, the average duration of the lives of a large number of individuals living in the same country is always found to be very nearly the same, insomuch that pecuniary risks depending on it, if undertaken in sufficiently large numbers, are among the least uncertain of all commercial speculations. A similar constancy is remarked in the results of statistical inquiries of every kind. The number of crimes of the same species committed in a year, the ratio of the number of acquittals to the number of trials, the number of conflagrations, of ships lost in a particular trade, of letters which pass through the post-office, of patients admitted into the public hospitals; in every case the numbers in a given time are observed to fluctuate between very narrow limits, and to approach nearer and nearer, as the observation is more extended, to fixed mean values.

This constant approximation to fixed ratios, which is proved by all experience, in the recurrence of events of the same kind, enables us to apply the calculus of probabilities to many of the most interesting questions connected with our social and political institutions; and to determine the average result of a series of coming events with as much precision as if their chances were determinate, and known *a priori*, like that of obtaining a given point with the throw of a die. Whatever be the nature of the phenomenon under consideration, whether it belong to the physical or moral order of things, the calculus is equally applicable when the requisite data have been determined from experience.

The foundations of the mathematical theory of probabilities were laid by Pascal and Fermat about the middle of the 17th century. Among some other questions relating to chances, the following was proposed to Pascal. "Two persons sit down to play on the condition that the one who first gains three games shall be the winner of the stakes. The first having gained two games, and the second one, they agree to leave off and divide the stakes in proportion to their respective probabilities of winning: what share is each entitled to take?" Pascal solved the question, but by a method which was applicable only to the particular case. Fermat, to whom it was communicated by Pascal, employed the direct and general method of combinations, and gave a solution which could be applied to the case of any number of players. His reasoning, however, did not at first appear to Pascal to be satisfactory, and a correspondence on the subject took place between these two illustrious geometers, which is preserved in their respective works, and throws some light on the history of mathematics in that age.[1]

About the same period Huygens composed his tract *De Ratiociniis in Ludis Aleæ*, which was first published in the *Exercitationes Geometricæ* of Schooten in 1658. This was the first systematic treatise which appeared on the doctrine of chances. It contained an analysis of the various questions which had been solved by Pascal and Fermat, and at the end five new questions were proposed, the solutions of which, simple as they may now appear, were then attended with considerable difficulty. The analysis of two of them was in fact given for the first time by Montmort, half a century after their publication. Huygen's tract was translated into English and published in 1692, with some additional remarks relative to the advantage of the banker in the game of Pharaon, in an *Essay on the Laws of Chance*, edited and supposed to have been written by Motte, then Secretary of the Royal Society.

James Bernoulli appears to have been the first who perceived that the theory of probability may be applied to much more important purposes than to regulate the stakes and expectations of gamesters, and that the phenomena, both of the moral and physical world, anomalous and irregular as they appear when viewed in detail, exhibit, when considered in large numbers, a constancy of succession which renders their occurrence capable of being submitted to numerical estimation. The *Ars Conjectandi*, published in 1713, seven years after the death of the author, contains a number of interesting questions relative to combinations and infinite series; but the most remarkable result which it contains is a theorem respecting the indefinite repetition of events, which may be said to form the basis of all the higher applications of the theory. It consists in this, that if a series of trials be instituted respecting an event which must either happen or fail in each trial, the probability becomes greater and greater, as the number of trials is increased, that the ratio of the number of times it happens, to the whole number of trials, will be equal to its *a priori* probability in a single trial; and that the number of trials may be made so great as to give a probability, approaching as nearly to certainty as we please, that the difference between the ratio of its occurrences to the number of trials, and the fraction which measures its *a priori* probability, will be less than any assigned quantity. Bernoulli informs us, that the solution of this important theorem had engaged his attention during a period of twenty years.

In the interval between the death of Bernoulli and the appearance of the *Ars Conjectandi*, Montmort published his *Essai d'Analyse sur les Jeux de Hazard*. The first edition was in 1708; the second, which is considerably extended, and enriched by several letters of John and Nicolas Bernoulli, appeared in 1713. The work possesses considerable merit; but being chiefly confined to the examination of the conditions of games of chance, many of which are now forgotten, it has lost much of its original interest.

About the same time, Demoivre began to turn his attention to the subject of probability, and his labours, which were continued during a long life, contributed greatly to the advancement of the general theory, as well as the extension of some of its most interesting applications. Demoivre's first publication on the subject was a Latin memoir *De Mensura Sortis*, in the *Transactions of the Royal Society* for 1711. His *Essay on the Doctrine of Chances* first appeared in 1716; a second edition in 1738; but the third and most valuable, including also his *Treatise on Annuities on Lives*, is dated 1756. This work contains a great variety of questions relating to chances, solved with much clearness and elegance; but it is chiefly remarkable for the theory of recurring series, there given for the first time, which is of important use in investigations of this kind, and is in fact equivalent to the methods employed in the modern calculus for the integration of equations of finite differences having constant co-efficients. Of the particular results obtained by Demoivre, one of the most important in reference to theory, is an extension of the theorem of James Bernoulli, above mentioned. It follows from Bernoulli's theorem, that if we have a given probability that the ratio of the number of occurrences of an event to the whole number of trials, will approach to the *a priori* probability of the event within certain given limits, those limits will become narrower and narrower, as the number of trials is multiplied; but in order to complete the theorem, it is necessary to assign the numerical value of the probability that in a large number of future trials, the number of occurrences will fall within assigned limits. For this purpose we must find the product of the natural numbers 1, 2, 3, 4, &c., up to the number of trials; an operation which, if attempted by direct multiplication, becomes very laborious, even when the number of trials is inconsiderable, and when the number is great, as 10,000 for example, is altogether beyond the reach of human industry. A formula was however discovered by Stirling, by means of which an approximate value of the product is found by the summation of a few of the first terms of a series which converges the more rapidly as the number of trials is greater. With the aid of this formula, Demoivre was enabled to assign the probability in question, and thus give a practical value to the theorem of Bernoulli.

The objects and important applications of the theory of probabilities having been made known by the works now mentioned, the subject has ever since been regarded as one of the most curious and interesting branches of mathematical speculation, and accordingly has received more or less attention from almost every mathematician of eminence. A great variety of questions connected with it and especially relating to lotteries, are interspersed in the volumes of the *Paris* and *Berlin Memoirs*, (particularly the latter,) by John and Nicolas Bernoulli, Euler, Lambert, Beguelin, and others. D'Alembert has likewise treated of the theory in several of the volumes of his *Opuscula;* and it is not a little remarkable, that in some instances its first principles should have been misunderstood by so ingenious and profound a writer. In the St. Petersburg Memoirs, (vol. v.) there is an interesting paper by Daniel Bernoulli on the relative values of the expectations of individuals who engage in play, or stake sums on contingent benefits, when regard is had to the difference of their fortunes; a consideration which, in many cases, it is necessary to take into account; for it is obvious, that the value of a sum of money to an individual, depends not merely on its absolute amount, but also on his previous wealth. On this principle Bernoulli has founded a theory of *moral expectation*, which admits of numerous and important applications to the ordinary affairs of life. The *Transactions of the Royal Society* for the years 1763 and 1764, contain two papers by the Rev. Mr. Bayes, with additions to the latter by Dr. Price, which deserve to be noticed, inasmuch as the principles on which the probability of an event is determined, when the event depends on causes of which the existence and influence are only presumed from experience, are there for the first time correctly laid down. The question proposed and solved by Bayes was this: a series of experiments having been made relative to an event, to determine the presumption there is, that the fraction which measures its probability falls within given limits.

One of the earliest applications of the theory of probability was to determine, from observations of mortality, the average duration of human life, and the value of pecuniary interests depending on its continuance or failure. This particular application appears to have been first thought of, or at least attempted to be carried into practical effect, in Holland, by Hudde and the celebrated pensionary De Witt; but the first tables of mortality, with the corresponding values of annuities on single lives, were constructed by our illustrious countryman Dr. Halley, and published in the Philosophical Transactions for 1693. For the history of this branch of the subject, we refer to the two articles, ANNUITIES and MORTALITY in this work. We may remark, however, that although the English writers, who have expressly treated of it, have almost without exception confined themselves to the explanation of the methods of computing annuity tables, and of determining from them the values of sums depending on life contingencies, the aid which this branch of economy derives from the general theory of probabilities, is by no means confined to the consideration of such elementary questions. The number of observations necessary to inspire confidence in the tables, the extent to which risks may be safely undertaken, the comparative weights of different sets of observations, and the probable limits of departure from the average results of previous observations in a given number of future instances, are all questions of the utmost importance, which come within the scope of the calculus, and cannot, in fact, be justly appreciated by any other means.

[1] *Œuvres de Blaise Pascal*, tome iv. Paris, 1819; *Opera Petri de Fermat*, Tolosæ, 1679.

The application of the theory of probability to the subject of jurisprudence, and the verdicts of juries and decisions of tribunals, has been discussed by the Marquis Condorcet in various articles in the *Encyclopédie Méthodique;* but more especially in his *Essai sur l'application de l'Analyse à la Probabilité des Decisions rendues à la Pluralité des Voix,* Paris 1785; a work of great ingenuity, and abounding with interesting remarks on subjects of the highest importance to humanity. James Bernoulli, it appears, had intended to treat jurisprudence as a branch of probability in the *Ars Conjectandi,* but his premature death prevented that work from being completed. There is a memoir on the subject by his nephew Nicolas, in the Leipsic Acts for 1711. The most important questions to be determined, are the number of jurors of which a jury ought to consist, and the majority which should be required to agree in a verdict in order to afford, on the one hand, the greatest probability that an accused person will not be wrongly condemned; and, on the other, to give to society the greatest security that its interests will not be compromised, by allowing too great facilities for the guilty to escape. This important subject has been treated more profoundly, and with numerical elements derived from much better data than existed in the time of Condorcet, in a recent work by Poisson, to which we shall presently allude.

Another of the moral subjects to which the theory of probability has been applied, and connected with the preceding, is the appreciation of the evidence of testimony. In matters of this kind, it is easy to see that the calculus must be founded almost entirely upon hypothetical data. The veracity of a witness can scarcely be made the subject of direct experiment; and by reason of the complicated circumstances with which the facts forming the subject of testimony are usually accompanied, and the numberless ways in which mankind are influenced by their passions, credulity, or ignorance, it is perhaps equally impossible to deduce an average value from the comparison of a great number of statements which have been ascertained to be true or false. Numerical results can therefore only be obtained by having recourse to hypotheses, and consequently must be considered as only probable approximations. The knowledge, however, which is thus obtained of the various combinations of the quantities concerned, affords important aid in guiding our judgments in complicated cases, and when we have to decide upon conflicting testimony. Approximations deduced from a train of accurate and systematic reasoning, are always to be preferred to the most specious arguments drawn from any other source.

The analysis of probability has been applied with signal advantage in many researches of Natural Philosophy, but especially in appreciating the mean errors of observations. Owing to the imperfections of sense and of instruments, physical magnitudes are only susceptible of being measured within certain limits of accuracy; and where the last degree of precision is indispensable, as in practical astronomy, it is only by means of a very great number of measures, compared with one another, and combined according to the methods which this calculus points out, that we can obtain the nearest approximation to the true values which the observations are capable of giving. The mean errors of observations were treated as questions of probability by Lagrange in the Turin *Memoirs* for 1773; but it is to Laplace that the theory owes its principal extension and most important results. The method of combining numerous equations of condition now universally followed, known as the method of *minimum squares,* and which Laplace has demonstrated to be that which leaves the least probable amount of error in the final equations, was made known by Legendre in an Appendix to his *Nouvelles Méthodes pour la Détermination des Orbites des Comètes,* published in 1806. A similar method, however, or rather the same, (for they are identical in principle,) had been discovered by Gauss, and employed by him for several years before the work of Legendre made its appearance.[1]

Laplace's great work, the *Théorie Analytique des Probabilités,* first published in 1812, is one of the most remarkable productions that has ever appeared in abstract science. The principles of the calculus, as well as the peculiar methods of analysis which it requires, and the most interesting and difficult questions which it presents, are here discussed in a far more general manner than had been attempted by any former writer on the subject; and it may be said, accordingly, to have placed the theory under an entirely new aspect. It is much to be regretted that so little pains have been taken by the illustrious author to render the work intelligible to the generality of mathematical readers. Consisting for the greater part of separate memoirs presented at different times to the Academy of Sciences, arranged without regard to symmetry or order, it abounds with repetitions which only serve to embarrass the student; while the deficiency of explanation combined with the subtlety of the analysis, and the inherent intricacy of the subject, render it often a painfully difficult task to seize the force of the demonstrations. Notwithstanding these defects, however, it forms one of the most splendid creations of mathematical genius; and is alike admirable, whether we regard the extension which has been given to the calculus, or the results which have been arrived at, or the tone of lofty philosophy in which subjects bearing on some of the most important concerns of mankind are treated.

Next to the *Théorie Analytique* of Laplace, the most important work which has hitherto appeared on the subject of probability is the recent one of Poisson, entitled, *Recherches sur la Probabilité des Jugements,* (Paris 1837.) Although it might be inferred from the title that this work relates only to a single though very interesting application of the theory, the greater part of it is devoted to the development and demonstration of the general principles, and the discussion of the principal questions which present themselves in the different applications; and it is only in the last of the five books of which it consists that the special subject to which the title refers is taken into consideration. In applying the theory to the decisions of tribunals, Condorcet and Laplace had been unable to obtain positive results from the want of authentic data; but the recent publication by the French government of the *Comptes Généraux de l'Administration de la Justice Criminelle,* in France, having furnished an immense collection of facts from which the requisite data could be obtained, Poisson was led to consider the subject anew, and the results of his investigations, which are of singular interest, are given in the work now mentioned. Poisson had already given a theory of the mean errors of observations in the *Additions* to the *Connaissance des Tems* for 1827 and 1832.

---

[1] *Theoria Motus Corporum Cœlestium,* p. 221.

It is in these two works of Laplace and Poisson that the higher and more abstruse parts of the theory of probabilities must be studied. A very clear exposition of the principles, accompanied with many interesting remarks on the uses and applications of the theory, is given by Lacroix in his valuable little work, *Traité Elémentaire du Calcul des Probabilités*, Paris 1822.

Since the time of Demoivre, the English treatises on the general theory of probability have neither been numerous, nor, with one or two exceptions, very important. Simpson's *Laws of Chance* (1740) contains a considerable number of examples, in the solution of which the author displays his usual acuteness and originality, but as they belong entirely to that class in which the chances are known *a priori*, they give no idea of the most interesting applications of the theory. Dodson's *Mathematical Repository* contains a large selection of the same kind. The Essay in the *Library of Useful Knowledge*, by Mr. Lubbock, gives a more comprehensive and philosophical, though an elementary view of the subject; but by far the most valuable work in the language is the Treatise in the *Encyclopedia Metropolitana*, by Professor De Morgan, 1837. In this very able production, Mr. De Morgan has treated the subject in its utmost generality, and embodied, within a moderate compass, the substance of the great work of Laplace.

Within the limits to which the present article must be confined, it would be hopeless to attempt giving a complete view of a branch of science which embraces so many complicated and intricate subjects of research, and which requires the aid of some of the most abstruse and recondite theories of the modern mathematics. In the higher applications of the theory, the analysis of many of the questions which arise, in order to be made intelligible, would require an extent of development and a parade of mathematical formulæ altogether incompatible with the plan and scope of this work. All that we can propose to ourselves, therefore, is to explain as briefly as may appear consistent with perspicuity, the general principles of the theory, and to give an outline of the manner in which these are applied to some of the more important questions which have been investigated by Laplace and Poisson. The examples will be selected with a view to shew the nature of the principal results of the mathematical theory, as well as the peculiar methods of analysis which are of most general application.

SECT. I. GENERAL PRINCIPLES OF THE THEORY OF PROBABILITY.

1. The term *probable*, in its popular acceptation, is used in reference to any unknown or future event, to denote that in our judgment the event is more likely to be true than not, or more likely to happen than not to happen. Without attempting to make an accurate enumeration of the various circumstances which are favourable or unfavourable to its occurrence, or to balance their respective influences, we suppose there is a preponderance on one side, and accordingly pronounce it to be probable that the event has occurred, or will occur, or the contrary.

2. If we can see no reason why an event is more likely to happen than not to happen, we say it is a *chance* whether the event will happen or not; or if it may happen in more ways than one, and we have no reason for supposing it will happen in any one of these ways rather than in another, we say it is a *chance* whether it will happen in any assigned way or in any other. Suppose, for example, an unknown number of balls of different colours to be placed in an urn, from which a ball is about to be extracted by a person blindfold. Here we have no reason for supposing that the ball about to be drawn will be of one colour rather than another, that it will be white rather than black, or red; and accordingly say it is a *chance* whether the ball will come out of a particular colour, or a different. In this instance, then, the term *chance* denotes, simply, the absence of a known cause. If, however, we are made acquainted with the number of balls in the urn, and the number there are of each of the different colours, the term is used in a definite sense. For instance, suppose the urn to contain ten balls, of which nine are white, and the remaining one black, we say there are nine chances in favour of drawing a white ball, and one chance only in favour of drawing the black ball. Chance, in this sense, denotes a *way of happening*, or a particular *case* or *combination* that may arise out of a number of other possible cases or combinations; and an event becomes probable or improbable according as the number of chances in its favour is greater or less than the number against it. *Chance* and *presumption* are also frequently used synonymously with *probability*.

3. The *mathematical probability* of any event is the ratio of the number of ways in which that event may happen to the whole number of ways in which it may either happen or fail. Thus, recurring to the previous example, the event, namely, the drawing of a ball from an urn containing 9 white balls and 1 black, may happen in 10 different ways, inasmuch as any one of the 10 balls may be drawn; but in one only of those ways will the event be a black ball; and therefore the probability of drawing the black ball is $\frac{1}{10}$. In like manner, as there are 9 different ways in which a white ball may be drawn, or 9 chances of drawing a white ball, and ten chances in all, the probability of drawing a white ball at the first trial is $\frac{9}{10}$. It follows immediately from this definition, that the probability of drawing a ball of either colour will remain the same, however the number of balls in the urn may be increased, provided those of each colour are increased in the same proportion. For instance, suppose the number of white balls to be 45, and the number of black balls to be 5; the number of chances in favour of drawing a black ball is 5, while there are 50 chances in all, consequently the probability of a black ball being drawn is $\frac{5}{50}=\frac{1}{10}$. In the same manner, the probability of drawing a white ball is $\frac{45}{50}=\frac{9}{10}$; the same as before. Generally, let E and F be two contrary events, that is to say, such that the one or the other of them must necessarily happen, and both cannot happen together; and let a be the number of chances or combinations which produce the event E, and b be the number of combinations which produce the event F, or cause the failure of E; then the probability that E will happen is $\frac{a}{a+b}$; and the probability that F will happen, or that E will *not* happen is $\frac{b}{b+a}$. In future, the term probability will be used only to signify mathematical probability.

4. It is to be carefully remarked, that the different chances or combinations which form the elements of probability are supposed to be perfectly equal. If this equality does not hold, and there is any circumstance respecting the event under consideration which renders one combination or set of combinations more likely to occur than another, the different combinations must be multiplied by numbers proportional to their respective facilities, after which the units in each multiplier may be regarded as so many distinct chances, from which the probability of the event will be found by the above formula. This is equivalent to saying that a combination or chance which is twice as likely to happen as another, must be regarded as two equal and similar combinations in comparison of that other; a proposition which is sufficiently obvious.

5. It follows from the above definition, that the probability of any contingent event is measured by a fraction less than unity, and may have any value between 0 and 1. It follows, also, that the sum of the two fractions which measure the probabilities of two contrary events is equal to unit, which is the measure of certainty, inasmuch as either the one or the other necessarily occurs. Thus, in the last example, the probability of the event E is $\frac{a}{a+b}$, and that of the contrary event F is $\frac{b}{a+b}$, and $\frac{a}{a+b}+\frac{b}{a+b}=1$. Hence if p denote the probability of any event E, and q the probability of the contrary event F, we have $q=1-p$. This consequence of the definition is of great importance in the calculation of probabilities.

6. We have here supposed the result of a trial to be necessarily one or other of two events E and F; but it is easy to imagine the trial to be of such a kind that it may give rise to any one of a number of events E, F, G, H, &c. each having a given number of chances in its favour. This case is represented by supposing an urn to contain balls of as many different colours or sorts as there are different events. Let the urn be conceived to contain a balls of the sort which produces the event E, b of the sort which produces F, c of the sort which produces G, and so on; and let $a+b+c+d$, &c. $=k$, so that k is the whole number of balls in the urn. The probabilities of the different events E, F, G, H, &c. are then, respectively, by the definition,

$$\frac{a}{k},\ \frac{b}{k},\ \frac{c}{k},\ \frac{d}{k},\ \&c.$$

the sum of which $=1$. In fact, if a ball be drawn at all, it must be of one or other of the different sorts contained in the urn; and consequently the sum of all the probabilities amounts to unit or certainty.

7. When an event is compounded of two or more simple events independent of each other, the probability of the compound event is equal to the product of the probabilities of the several simple events of which it is compounded. Let us imagine two urns, A and B, of which A contains a white balls and b black, and B contains a' white and b' black. Make $a+b=c$, and $a'+b'=c'$, and let the compound event whose probability is to be determined be the drawing of a white ball from both urns. Now, as each of the c balls in A may be drawn with any one of the c' balls in B, the whole number of ways in which the balls in A may be differently combined by pairs with the balls in B, or the whole number of possible cases is cc'. But the number of cases favourable to the compound event is evidently the number of different ways in which a white ball may be drawn from A with a white ball from B, and therefore equal to aa'. Hence by the definition (4), the probability that a white ball will be drawn from both urns is $\frac{aa'}{cc'}$. Now, if p denote the probability of drawing a white ball from A, and p' that of drawing a white ball from B, we have by the definition $p=\frac{a}{c}$, and $p'=\frac{a'}{c'}$; whence $\frac{aa'}{cc'}=pp'$.

In general, let p denote the probability of an event E, p' that of another event E′, p'' that of a third E″, and so on; then the probability of the concourse of the events E, E′, E″, &c., or the probability that they will all happen, is $p\times p'\times p''$, &c.; that is to say, the probability of an event compounded of any number of simple and independent events, is the product of the respective probabilities of the several simple events.

The probabilities that the several simple events E, E′, E″ &c., will *not* all happen, or that some of them will happen and others fail, are easily determined in the same manner; it will be sufficient to indicate their several expressions. Suppose there are only three simple events, of which the probabilities are respectively p, p', and p''; and let $q=1-p$, $q'=1-p'$, $q''=1-p''$. The product $pq'q''$ expresses the probability of the compound event which consists in E happening and E′ and E″ both failing; $qp'q''$ is the probability that E′ will happen, and that E and E″ will both fail; $pp'p''$ is the probability they will all three happen; $1-pp'p''$ is the probability they will *not* all three happen, or that one of them *at least* will fail; $qq'q''$ is the probability they will all fail; and $1-qq'q''$ is the probability they will *not* all three fail, or that one *at least* of them will happen.

8. As an example of the application of this rule, suppose it were required to assign the probability of throwing aces, at one throw, with two common dice. As a common die has six symmetrical faces, there are in respect of each die six ways equally possible, in which the simple event may happen. The probability therefore of throwing ace with one die is $\frac{1}{6}$, that is, $p=\frac{1}{6}$. In respect of the second die, we have also $p'=\frac{1}{6}$; hence the probability of the compound event, or that aces will be thrown is $pp'=\frac{1}{6}\times\frac{1}{6}=\frac{1}{36}$. The probability that aces will *not* be thrown at any assigned trial is therefore (5) $1-\frac{1}{36}=\frac{35}{36}$; and the *odds* against throwing aces at any given trial are 35 to 1.

Again, suppose two numbers, each consisting of 7 digits, to be taken at random, (for instance from a table of logarithms), and let it be proposed to assign the probability that the substraction of the one from the other will be performed without its being necessary, in any case, to increase the upper figure. Here, as each digit may have any one of the ten values from 0 to 9 both inclusive, and as each of those values in the upper line may be combined with any one of them in the lower line, there are 100 different combinations or equally possible cases for each partial substraction. Now, if the upper figure be 0, there is only one of those cases favourable to the event, or which will admit of the substraction being performed, namely, when the figure below is also 0. If the upper figure be 1, there are two cases favourable, namely, those in which the under figure is 0 or 1. If the upper figure be 2, there are three favourable cases, namely, when the under figure is 0, 1, or 2. Proceeding in this way through all the digits, the whole number of favourable cases is found to be

$$1+2+3+4+5+6+7+8+9+10=55.$$

Hence, for each partial substraction there are 55 favourable cases out of 100 possible cases; therefore (4) the probability that any one of the figures in the upper line is not less than the corresponding figure in the under line is $\frac{55}{100}$; and we have $p=p'=p''=\&c.=\frac{55}{100}$ for the probability of each of the seven simple events or partial substractions, whence, by (7), the probability of the compound event is

$$p\times p'\times p''\times\&c.=\left(\frac{55}{100}\right)^7=(\cdot 55)^7=0152243,$$

which is less than $\frac{1}{65}$, and greater than $\frac{1}{66}$.

9. When an event may happen in several different ways, each independent of the others, the probability of the event is the sum of all the partial probabilities taken in respect of each of the different ways.

Suppose there are n different urns A_1, A_2, A_3......A_n, each containing balls of two colours, white and black, and let the whole number of balls in each urn respectively, be

$$c_1,\ c_2,\ c_3,\ldots\ldots c_n,$$

and the number of white balls in each be

$$a_1,\ a_2,\ a_3,\ldots\ldots a_n,$$

and let the event E be the extraction of a white ball in drawing a ball from any urn at random. In this case there are n different ways, all equally probable, in which the event may happen, for it may be drawn with equal facility from any one of the urns. The probability that the ball will be drawn from any given urn, A_1, is therefore $\frac{1}{n}$; and if it be drawn from this urn, the probability of its being white is $\frac{a_1}{c_1}$; therefore, by (7), the probability of a white ball being drawn from A_1 is $\frac{1}{n} \cdot \frac{a_1}{c_1}$. In like manner the probability of a white ball being drawn from A_2 is shewn to be $\frac{1}{n} \cdot \frac{a_2}{c_2}$; from A_3 to be $\frac{1}{n} \cdot \frac{a_3}{c_3}$, and so on. Denoting therefore by p the whole probability of the event E, the proposition affirms that

$$p=\frac{1}{n}\left(\frac{a_1}{c_1}+\frac{a_2}{c_2}+\frac{a_3}{c_3}\ldots\ldots+\frac{a_n}{c}\right).$$

To prove this, let the fractions $\frac{a_1}{c_1}, \frac{a_2}{c_2}$ &c. be reduced to a common denominator, and suppose the equivalent fractions to be

$$\frac{a_1}{\gamma},\ \frac{\alpha_2}{\gamma},\ \frac{a_3}{\gamma}.\ \ \ldots\ldots\ \frac{a_n}{\gamma}.$$

We may now conceive the urns $A_1, A_2, A_3 \ldots A_n$ to be replaced by others, each containing the same number, γ, of balls, and of which the first contains a_1 white balls, the second a_2, and so on; and it is evident that the chance of a white ball being drawn from this new system of urns will be precisely the same as it was for a white ball being drawn from the first system. Now the probability of drawing a white ball from the new system will not be altered by placing the whole of the $n\gamma$ balls in a single urn, for they may still be conceived as arranged in groups, disposed in any manner whatever, each group containing the same number of balls, and the same proportion of white to black as were in the separate urns; and as each group contains the same number of balls, the chance of laying the hand on any one group is the same as that of laying it on any other. The probability of drawing a white ball from the single urn, is therefore the same as for drawing it from the group of separate urns which contain each the same number of balls. But the probability of drawing it from the single urn is the ratio of the number of white balls contained in the urn to the number of both colours, therefore (this probability being p) we have

$$p=\frac{1}{n\gamma}(a_1+a_2+a_3\ldots\ldots+a_n);$$

whence, substituting for $\frac{a_1}{\gamma}, \frac{a_2}{\gamma}$, &c., their respective values, $\frac{a_1}{c_1}, \frac{a_2}{c_2}$, &c., we have

$$p=\frac{1}{n}\left(\frac{a_1}{c_1}+\frac{a_2}{c_2}+\frac{a_3}{c_3}\ldots\ldots+\frac{a_n}{c_n}\right).$$

As a particular case suppose three urns A, B, C to be placed together, of which A contains 2 white balls and 1 black; B 3 white bails and 2 black, and C 4 white and 3 black, and let it be required to determine the probability p of a white ball being drawn from the group by a person who is ignorant of the contents of the different urns. As there is no reason for selecting one urn in preference to another, the probability that he will put his hand into the urn A is $\frac{1}{3}$; and if he draw from this urn the probability that a white ball will be drawn is $\frac{2}{3}$, there being 2 cases favourable to that event, and 3 cases in all. The probability of both events is therefore $\frac{1}{3}\quad\frac{2}{3}=\frac{2}{9}$. In like manner, the probability of the ball being drawn from B is $\frac{1}{3}$; and if drawn from B the probability of its being white is $\frac{3}{5}$; therefore, the probability of this compound event is $\frac{1}{3} \times \frac{3}{5}=\frac{1}{5}$. Lastly, the probability of the ball being drawn from C is $\frac{1}{3}$; and if drawn from C the probability of its being white is $\frac{4}{7}$; therefore, the probability of this compound event is $\frac{1}{3} \times \frac{4}{7}=\frac{4}{21}$. Hence, by the proposition now demonstrated, the complete probability of the event E is

$$p=\tfrac{2}{9}+\tfrac{1}{5}+\tfrac{4}{21}=\tfrac{193}{315}.$$

If all the balls had been placed in a single urn, the probability of drawing a white ball would have been $\frac{9}{15}$, for there are $3+5+7=15$ balls in all, of which $2+3+4=9$ are white. But $\frac{9}{15}=\frac{189}{315}$; a fraction which differs sensibly from $\frac{193}{315}$, the measure of the probability of the same event when the balls are distributed in the manner above supposed amongst the different urns. The distinction between the two cases is important.

10. The rule laid down in (7) for finding the probability of a compound event applies alike whether the simple events are determined simultaneously or in succession. In fact, when the simple events are entirely independent of each other, the chances which determine the compound event are not influenced in any way by the intervention of time. Suppose, for example, the compound event to be the throwing of a certain number of points with a given number m of dice; the chances for and against the event are obviously the same whether the m dice are thrown at once, or a single die is thrown m times successively. But as the determination of the probability of a compound event is in general facilitated by supposing the simple events to be decided one after the other, it will be convenient to view the subject in this light in explaining the method of forming the different combinations of the chances by which the probabilities of compound events are determined.

SECT. II. OF THE PROBABILITY OF EVENTS DEPENDING ON A REPETITION OF TRIALS, OR COMPOUNDED OF ANY NUMBER OF SIMPLE EVENTS, THE CHANCES IN RESPECT OF WHICH ARE KNOWN *A PRIORI*, AND CONSTANT.

11. Suppose an urn to contain $a+b$ balls, a white and b black, and let a ball be successively drawn, and replaced in the urn after each drawing, in order that the chances in favour of drawing a ball of either colour may be the same in every trial, and let it be required to find the respective probabilities of the different possible results of any number of drawings.

Let us first suppose the number of trials to be two. The event may happen in any of these four different ways: first white, second white; first white, second black; first black, second white; first black, second black. Assuming W to represent the simple event which consists in the drawing of a white ball, and B that of a black ball, and supposing the order of the arrangement of the two letters to correspond with the order of succession of the simple events, the four possible cases or combinations will be represented thus:—

WW, WB, BW, BB.

Now let the probability of drawing a white ball in any trial be p, and that of drawing a black ball be q, (whence, $p=\frac{a}{a+b}$, $q=\frac{b}{a+b}$) the probabilities of the four possible compound events are by (7) respectively as under:

probability of WW $=p \times p=p^2$
of WB $=p \times q=pq$
of BW $=q \times p=pq$
of BB $=q \times q=q^2$

If we disregard the order of succession, and consider the two arrangements WB and BW, which are equally probable, as forming the same compound event, namely, a ball of both colours in the two trials, the probability of this event, by (9), becomes $2pq$. The sum of the probabilities of all the possible arrangements is therefore

$$p^2+2pq+q^2=(p+q)^2;$$

whence it appears that the probabilities of the different arrangements in two trials are respectively the terms of the development of the binomial, $(p+q)^2$.

Let us next suppose the number of trials to be three.

The different arrangements that may be formed of the simple events in three trials, with the probability of each respectively, are as follows :—

WWW, probability of which $=ppp=p^3$
WWB, ... $=ppq=p^2q$
WBW, ... $=pqp=p^2q$
BWW, ... $=qpp=p^2q$
WBB, ... $=pqq=pq^2$
BWB, ... $=qpq=pq^2$
BBW, ... $=qqp=pq^2$
BBB, ... $=qqq=q^3$

It thus appears that the probability of obtaining two events of one kind, and one of the other, is the same in whatever order they succeed each other, and, in fact, is independent of the order. Disregarding, then, the order of succession, and considering the combination of two white balls with one black, in whatever order they may be arranged, as the same compound event, the probability of its occurrence *in any order whatever*, being the sum of its probabilities in each particular order (9), is $3p^2q$. In like manner, regarding the combination of two black balls with one white, in any order of arrangement, as the same compound event, its probability is $3pq^2$. The compound event resulting from three trials must then happen in one of four different ways, namely, 3 white balls; 2 white, combined with 1 black, in any order; 2 black, combined with one white, in any order; or, lastly, 3 black; and the sum of the probabilities of these different cases is

$$p^3+3p^2q+3pq^2+q^3=(p+q)^3.$$

Hence the probabilities of all the different possible combinations in three trials are respectively given by the development of the binomial $(p+q)^3$.

12. In general, let p denote the probability of any simple event E, then the probability of E happening twice in two trials is p^2, of happening thrice in 3 trials p^3, and of happening m times in m successive trials, p^m. In like manner, the probability of the contrary event F being q $(p+q=1)$, the probability of F happening n times in n successive trials is q^n. Hence (7) the probability of E happening m times, and then F happening n times in succession, in $m+n$ trials, is p^mq^n. But the probability of these events happening in any assigned order is the same as that of their happening in any other assigned order; therefore p^mq^n is the measure of the probability that E will occur m times, and F will occur n times in a determinate order. Now, let $m+n=h$, and let U be the number of different ways in which m events E, and n events F, can be combined in h trials, and P be the probability of any one of these combinations whatever, or the probability of E occurring m times, and F occurring n times in h trials, without regard to the order in which they succeed each other, we have then

$$\text{P}=\text{U}p^mq^n.$$

In order to determine the value of U, we may suppose the events in question to be so many different things represented by the letters A, B, C, D, E, &c. of which there are m of one kind, and n of another, and make $m+n=h$; then by the algebraic theory of combinations, we have

$$\text{U}=\frac{1\,.\,2\,.\,3\ldots\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots\ldots m\times 1\,.\,2\,.\,3\ldots\ldots n}.$$

This value of U is symmetrical in respect of m and n, and may be otherwise written in either of the two following forms,

$$\text{U}=\frac{h(h-1)(h-2)\ldots\ldots\ldots h-m+1}{1\,.\,2\,.\,3\ \ldots\ldots\ldots\ m},$$

$$\text{U}=\frac{h(h-1)(h-2)\ldots\ldots\ldots h-n+1}{1\,.\,2\,.\,3\ \ldots\ldots\ldots\ n},$$

which shew that the probability P, or the product $\text{U}p^mq^n$ is the $(m+1)$th term of the development of the binomial $(p+q)^h$ arranged according to the increasing powers of p, or the $(n+1)$th term of the same development arranged according to the increasing powers of q. Hence we conclude that when p and q remain constant, the probabilities of all the different compound events which can be formed by the combination of the simple events E and F in h trials, are expressed by the different terms of the formula $(p+q)^h$ expanded by the binomial theorem.

The whole number of possible cases is evidently $h+1$, for in h experiments, E may occur h times, $h-1$ times, $h-2$ times......$h-h$ times; this last being the case in which the contrary event F occurs in all the trials. The different cases are unequally probable, both by reason of the greater or smaller number of combinations by which they may be produced, and which in reference to each case is represented by U, and by reason of the inequality between p and q. It will be shewn afterwards, that when $p=q$, and h is a whole number, the most probable case is that in which the occurrences of E and F are equal; and if h is an odd number, the two most probable cases are those in which the difference in the number of occurrences of E and the number of occurrences of F is unity.

13. In order to place the proposition now demonstrated in a clearer light, let us consider separately the different terms of the development of $(p+q)^h$, namely,

$$p^h+hp^{h-1}q+\frac{h(h-1)}{1\,.\,2}p^{h-2}q^2\ \ldots\ldots\ldots\ldots\ldots\ldots\ldots$$
$$+\frac{h(h-1)(h-2)\ldots\ldots h-n+1}{1\,.\,2\,.\,3\ \ \ldots\ldots\ \ n}p^{h-n}q^n$$
$$\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots+q^h.$$

The first term p^h expresses the probability that the event E will in every one of the h trials. The second term $hp^{h-1}q$ expresses the probability that E will occur $h-1$ times, and F once, without distinction of order; that is to say F may happen at the first or last or any intermediate trial. If a determinate succession is proposed, for example, that of $h-1$ times the event E in succession, and F in the next trial, the probability of the event in the assigned order is found by suppressing the coefficient h, and is consequently $p^{h-1}q$.

The third term $\frac{h(h-1)}{1\,.\,2}p^{h-2}q^2$ expresses the probability that the result of h trials will be $h-2$ times the event E, and twice the event F, without distinction of order. If a particular order be assigned, it is necessary to suppress the coefficient, and the probability of the simple events occurring in that particular order is $p^{h-2}q^2$.

The general term $\frac{h(h-1)(h-2)\ldots\ldots h-n+1}{1\,.\,2\,.\,3\ \ldots\ldots\ n}p^{h-n}q^n$ expresses the probability that the result of h trials will be $(h-n)$ times the event E, and n times the event F in any order. The probability of $(h-n)$ times E and n times F in an assigned order is $p^{h-n}q^n$.

14. If we suppose the event E to be such that the chances in favour of its happening or failing are equal, that is, if $p=q=\frac{1}{2}$, the different terms of the binomial $(p+q)^h$, on suppressing the coefficients, become all equal; so that a particular order being assigned in each of the possible cases or combinations, all the cases become equally probable. Thus, suppose a shilling to be tossed 100 times in succession, the probability of head turning up in every trial is $(\frac{1}{2})^{100}$. The probability of 50 heads and 50 tails in any assigned order is $(\frac{1}{2})^{50}\times(\frac{1}{2})^{50}=(\frac{1}{2})^{100}$; if $m+n=100$, the probability of m heads and n tails is also $(\frac{1}{2})^m(\frac{1}{2})^n=(\frac{1}{2})^{m+n}=(\frac{1}{2})^{100}$. Hence the probability of any compound event formed by the combination of two simple contrary events succeeding each other in an assigned order, and each having the same probability, is independent of the ratio of the simple events, and depends only on the number of trials. Before the trials, it is an even wager that head will be turned up in succession 100 times, and that the result of 100 trials will be 50 heads and 50 tails in a given order of succession, or any proportion

of heads to tails in an order arbitrarily chosen. This consideration is frequently lost sight of in reasoning about those events of the natural world, which are termed extraordinary and miraculous. If in tossing a shilling 100 times into the air, the number of heads turned up is found nearly equal to the number of tails, the event excites no surprise; something like it was expected. On the contrary, if the difference between the number of heads and the number of tails is considerable, the event is termed extraordinary; and if head turned up in every trial without exception, we should scarcely be persuaded that such an event was entirely the result of chance, and independent of a special cause. Nevertheless, the *a priori* probability that every trial will give head, is precisely the same as the probability of throwing any given number of heads and tails in an assigned order of succession. It will, however, be proved afterwards, that if such an event as throwing head 100 times in succession were actually observed, the probability of a special cause having intervened, would approach very nearly to certainty.

15. Hitherto we have supposed the compound event to be formed by the combination of two simple events only, E and F, one of which necessarily excludes the other. Let us now suppose there are any number of simple events, E_1, E_2, E_3, &c. of which the respective probabilities are p_1, p_2, p_3, &c. and such that one or other of them necessarily happens in each trial, so that $p_1+p_2+p_3+$, &c. $=1$, and determine the probability of any assigned combination of them in a given number of trials. This case may be represented by supposing an urn to contain a number of balls of as many different colours as there are distinct events; the event E_i will be the drawing of a ball of the colour i, and its probability p_i will be the fraction whose numerator is equal to the number of balls of the colour i, and denominator the whole number of balls in the urn. Now the probability of the event E_1 happening m times in succession is p_1^m by (12); that of E_2 happening n times in succession is p_2^n; that of E_3 happening r times in succession p_3^r; and so on. Therefore (7) the probability of the compound event which is formed by the occurrence of m times E_1, n times E_2, r times E_3, and so on, these events succeeding each other in order, is the product $p_1^m\,p_2^n\,p_3^r$, &c. But the probability of the simple events succeeding each other in any particular order is the same as that of their succeeding in any other assigned order (12); consequently, if U′ denote the number of different ways in which m events E_1, n events E_2, r events E_3, &c. can be combined, or succeed each other, and P′ be the probability of the compound event in any order whatever, we have,

$$P'=U'p_1^m\,p_2^n\,p_3^r,\ \&c.$$

Assuming $h=m+n+r+$, &c. we have also by the theory of combinations,

$$U'=\frac{1\,.\,2\,.\,3\ldots\ldots\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots m\times1\,.\,2\,.\,3\ldots n\times1\,.\,2\,.\,3\ldots r\times\ \&c.}$$

the factor U′ being the coefficient of the term which has for its multiplier $p_1^m\,p_2^n\,p_3^r$, &c. in the expansion of the multinomial $(p_1+p_2+p_3+\ \&c.)^h$, whence

$$P'=\frac{1\,.\,2\,.\,3\ldots\ldots\ldots\ldots\ldots h}{1.2.3\ldots m\times1.2.3\ldots n\times1.2.3\ldots r\times\&c.}p_1^m\,p_2^n\,p_3^r,\&c.$$

We shall now proceed to give some examples of the applications of the preceding formulæ.

16. Let it be proposed to assign the probability P, of throwing ace *once*, and not oftener, in four successive throws of the same die.—Simpson, p. 15.

Here, the chance of throwing ace in a single trial being $\frac{1}{6}$, we have $p=\frac{1}{6}$, and consequently $q=\frac{5}{6}$, and also $h=4$. Now the compound event being the occurrence of the simple event E, whose probability is p, once, and of the contrary event F three times, the probability of the compound event is that term of the development of $(p+q)^4$ which is multiplied by pq^3. If, therefore, in the formula,

$$P=\frac{1\,.\,2\,.\,3\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots m\times1\,.\,2\,.\,3\ldots\ldots n}p^mq^n,$$

we make $p=\frac{1}{6}$, $q=\frac{5}{6}$, $h=4$, $m=1$, $n=3$, we shall have

$$P=\frac{1\,.\,2\,.\,3\,.\,4}{1\times1\,.\,2\,.\,3}\times\frac{1}{6}\times\left(\frac{5}{6}\right)^3=\frac{125}{324},$$

which is the probability required, and the same as that of throwing one ace, and not more than one, at a single throw with 4 dice.

The probability of the contrary event, that is to say, the probability of either not throwing an ace at all, or of throwing more aces than one is $1-\frac{125}{324}=\frac{199}{324}$; and therefore the odds against throwing one ace and no more in 4 throws of a common die are 199 to 125, or 8 to 5 very nearly.

17. If in this example it had been proposed to assign the probability of throwing ace once *at least*, instead of once and not more, it would have been necessary to have included those cases in which the ace occurs twice, or three times, or in each of the four trials. The binomial $(p+q)^4$ gives

$$p^4+4p^3q+6p^2q^2+4pq^3+q^4,$$

the first term of which expresses the probability of throwing ace four times in succession; the second that of throwing ace three times, and another number once; the third that of throwing ace twice, and a different face twice; the fourth that of throwing ace once, and a different face three times; and the fifth that of throwing a different face in each of the four trials. But as every one of these compound events, excepting the last, satisfies the condition of ace being thrown once at least, the whole probability of that event must be the sum of the probabilities of the different events by which it may be produced (9) and is consequently

$$\left(\frac{1}{6}\right)^4+4\left(\frac{1}{6}\right)^3\frac{5}{6}+6\left(\frac{1}{6}\right)^2\left(\frac{5}{6}\right)^2+4\left(\frac{1}{6}\right)\left(\frac{5}{6}\right)^3=\frac{671}{1296}$$

In general, the sum of the first $n+1$ terms of $(p+q)^h$ expresses the probability of obtaining *not less* than $h-n$ events, the probability of each of which is p, or *not more* than n contrary events, the probability of each of which is q.

Since $p+q=1$, the sum of all the terms of the series produced by the expansion of $(p+q)^h$ is equal to unit, and therefore the sum of any number of the terms is equal to unit diminished by the sum of the remaining terms. This consideration frequently gives the means of abridging the calculations. Thus, in the preceding example, instead of expanding the binomial $(\frac{1}{6}+\frac{5}{6})^4$ in order to find the probabilities of throwing 4 aces, 3 aces, 2 aces, and 1 ace only, in a series of 4 trials, we might have sought the probability of not throwing ace at all. The probability of not throwing ace in a single trial is $\frac{5}{6}$, and therefore (7) that of not throwing it in 4 trials is $(\frac{5}{6})^4=\frac{625}{1296}$. Hence the probability of the contrary event, namely, that ace will be thrown once or oftener, is $1-\frac{625}{1296}=\frac{671}{1296}$; the same as before.

18. Let a shilling be tossed; what is the probability that more than 3 heads will turn up in the first 10 trials? In this case, $p=\frac{1}{2}$, $q=\frac{1}{2}$, $h=10$; therefore $(p+q)^h=(\frac{1}{2}+\frac{1}{2})^{10}=(\frac{1}{2})^{10}(1+1)^{10}$. Now the last term of this development expresses the probability that head will not turn up in any one of the ten trials; the last but one, the probability that it will turn up once; the last but two, the probability that it will turn up twice; and the last but three, the probability that it will turn up three times; therefore the four last terms include all the different ways in which the ten trials give not more than three heads; and their sum consequently expresses the probability that *not more* than 3 heads will be thrown. Now the last four (or first four) terms of the expansion of $(1+1)^{10}$ are

$$1\ ,\ 10\ ,\ \frac{10\cdot9}{1\cdot2},\ \ \frac{10\cdot9\cdot8}{1\cdot2\ 3},$$

and their sum is 176, which multiplied by $(\frac{1}{2})^{10}=\frac{1}{1024}$, gives $\frac{176}{1024}$, for the probability that not more than 3 heads will turn up; whence the probability of the contrary event or that more than 3 heads will be thrown, is $1-\frac{176}{1024}=\frac{848}{1024}=\frac{53}{64}$; and the odds in favour of throwing heads more than three times in 10 trials are 53 to 11.

19. A and B engage in play; the probability of A's winning a game is p, and the probability of B's winning a game is q; required the probability P, of A's winning m games before B wins n games, the play being supposed to terminate when either of those events has occurred.

It is evident that the question must be decided *at the latest*, by the $(m+n-1)$th game; for supposing $m+n-2$ games to have been played, there is only one combination according to which the match can remain undecided, namely, that in which A has won $m-1$, and B $n-1$ games; and in this case the next game necessarily decides the match.

Suppose $m+x$ games to have been played. The probability that of these games m have been won by A, and x by B, is represented by the term of the binomial $(p+q)^{m+x}$ in which the factor $p^m q^x$ occurs (13); which term is

$$\frac{1\,.\,2\,.\,3 \ldots\ldots m+x}{1\,.\,2\,.\,3 \ldots\ldots m \times 1\,.\,2\,.\,3 \ldots\ldots x} p^m q^x.$$

But A cannot win m games out of $m+x$ exactly unless he wins the last game, for otherwise he must have won m games out of $m+x-1$, if not out of a smaller number. In order therefore that A may win m games out of $m+x$ exactly, it is necessary in the first place that he wins $m-1$ out of $m+x-1$ in any order, and then that he wins also the next game. Now the probability of his winning $m-1$ games out of $m+x-1$ in any order (13) is

$$\frac{1\,.\,2\,.\,3 \ldots\ldots m+x-1}{1\,.\,2\,.\,3 \ldots m-1 \times 1\,.\,2\,.\,3 \ldots x} p^{m-1} q^x;$$

and the probability of his winning the following game is p, whence the probability of both events is (7)

$$\frac{1\,.\,2\,.\,3 \ldots\ldots m+x-1}{1\,.\,2\,.\,3 \ldots\ldots m-1 \times 1\,.\,2\,.\,3 \ldots\ldots x} p^m q^x,$$

which, therefore, expresses the probability of A's winning m games out of $m+x$ exactly.

If we suppose $x=0$, this formula becomes p^m, which is the probability of A's winning m games in succession. If $x=1$, it becomes $mp^m q$, the probability that A wins m games out of $m+1$. If $x=2$, it becomes $\frac{m(m+1)}{1\,.\,2} p^m q^2$, the probability that A wins m games out of $m+2$. If $x=3$, it becomes $\frac{m(m+1)(m+2)}{1\,.\,2\,.\,3} p^m q^3$, the probability that A wins m games out of $m+3$; and so on. Continuing this process till we arrive at the term multiplied by $p^m q^x$, the sum of the probabilities of all the different compound events is

$$p^m \left\{ 1+mq+\frac{m(m+1)}{1\,.\,2} q^2 \ldots + \frac{m(m+1) \ldots m+x-1}{1\,.\,2 \;\ldots\; x} q^x \right\};$$

which expresses the probability of A's winning m games out of a number *not greater* than $m+x$.

Now it has been shewn, that the match is necessarily decided by $(m+n-1)$ games; consequently the solution of the question is obtained by substituting $n-1$ for x in the last formula, which will then express the probability of A's winning m games in any order, out of a number not greater than $m+n-1$. On making this substitution, we obtain

$$\mathrm{P}=p^m \left\{ 1+mq+\frac{m(m+1)}{1\,.\,2} q^2 \ldots\ldots\ldots\ldots \right.$$
$$\left. \ldots\ldots\ldots\ldots + \frac{m(m+1) \ldots m+n-2}{1\,.\,2 \;\ldots\; n-1} q^{n-1} \right\}.$$

The probability Q that the match will be decided in favour of B, or that B will win n games out of a number not greater than $m+n-1$, is found by changing m into n, and p into q, and is therefore

$$\mathrm{Q}=q^n \left\{ 1+np+\frac{n(n+1)}{1\,.\,2} p^2 \ldots\ldots\ldots\ldots \right.$$
$$\left. \ldots\ldots\ldots\ldots + \frac{n(n+1) \ldots\ldots m+n-2}{1\,.\,2 \;\ldots\ldots\; m-1} p^{n-1} \right\}.$$

As an example, let us suppose $p=\frac{2}{3}$, $q=\frac{1}{3}$, $m=4$, and $n=2$. The probability of A's winning the match, or the value of P, becomes

$$\left(\frac{2}{3}\right)^4 \left\{ 1+4\,.\,\frac{1}{3} \right\} = \frac{112}{243};$$

and the probability of B's winning the match, or the value of Q,

$$\left(\frac{1}{3}\right)^2 \left\{ 1+\frac{4}{3}+\frac{2\,.\,3}{1\,.\,2}\left(\frac{2}{3}\right)^2+\frac{2\,.\,3\,.\,4}{1\,.\,2\,.\,3}\left(\frac{2}{3}\right)^3 \right\} = \frac{131}{243}.$$

In this example the skill of A is supposed to be twice as great as that of B, and the number of games that must be won by him in order to gain the match is also twice as great as the number required to be won by B in order that B may gain; one might therefore suppose, that when they begin to play the chances in favour of each are equal. But the result shews that the chances in favour of A are fewer than those in favour of B in the proportion of 112 to 131; whence it appears that it would be unsafe to wager that a player who has two chances in his favour while his adversary has only one, will gain four games before his adversary shall have gained two.

Suppose A and B, engaged in play, agree to leave off before the match is decided, it is evident that the stakes ought to be shared between them in proportion to their respective probabilities of winning, and consequently the share of each is found from either of the above expressions for P and Q. This was one of the questions proposed by the Chevalier de Méré to the celebrated Pascal, to which allusion has already been made.

20. An urn contains $n+1$ balls, marked with the numbers 0, 1, 2, 3……n; a ball is successively drawn and replaced in the urn, so that the chance of drawing any given number remains the same in each trial, what is the probability that in h trials the sum of the numbers drawn will be equal to s?[1]

The solution of this problem depends on the number of ways in which the number s can be formed by the addition of h different numbers, each of which may have any value from 0 to n. If we suppose the numbers marked on the balls to be indexes of a certain quantity x, and develope the expression $(x^0+x^1+x^2 \ldots\ldots + x^n)^h$, the coefficient of any term of the development will indicate the number of different ways in which the balls may be drawn, so that the sum of the numbers drawn in h trials shall be equal to the sum of the indexes of x in that term. If, therefore, we denote by N the coefficient of that term of the development in which the sum of the indexes is s, then N will be the number of cases favourable to the event. But the whole number of possible cases is $(n+1)^h$; therefore the probability of the event is $\mathrm{N} \div (n+1)^h$.

On account of the particular form of the polynomial in question, the value of N is found without difficulty.

Because $x^0+x^1+x^2 \ldots\ldots + x^n = \frac{1-x^{n+1}}{1-x}$, therefore $(x^0+x^1+x^2 \ldots\ldots + x^n)^h=(1-x^{n+1})^h(1-x)^{-h}$. Now, expressing these two factors in series, we have $(1-x^{n+1})^h$

$$=1-hx^{n+1}+\frac{h(h-1)}{1\,.\,2}x^{2(n+1)}-\frac{h(h-1)(h-2)}{1\,.\,2\,.\,3}x^{3(n+1)}+\&c.$$

$$(1-x)^{-h}=1+hx+\frac{h(h+1)}{1\,.\,2}x^2+\frac{h(h+1)(h+2)}{1\,.\,2\,.\,3}x^3+\&c.;$$

and the coefficients of the several terms of the product of these two series in which the sum of the indexes is s will be found as follows:—

---

[1] Demoivre, *Miscellanea Analytica*, p 196; Laplace, *Essai sur les Probabilités*, p. 253, et seq.

(1.) Multiply the first term of the first series by that term of the second series of which the argument is x^s; the coefficient of the product will be $\frac{h(h+1)(h+2)\ldots\ldots h+s-1}{1\,.\,2\,.\,3\quad\ldots\ldots\quad s}$

(2.) Multiply the second term of the first series by that term of the second series which has for its argument x^{s-n-1}; the coefficient of the product will be

$$-h\times\frac{h(h+1)(h+2)\ldots\ldots h+s-n-2}{1\,.\,2\,.\,3\quad\ldots\ldots\quad s-n-1}.$$

(3.) Multiply the third term of the first series by that term of the second series which has for its argument $x^{s-2(n+1)}$; the coefficient of the product will be

$$\frac{h(h-1)}{1\,.\,2}\times\frac{h(h+1)(h+2)\ldots\ldots h+s-2n-3}{1\,.\,2\,.\,3\quad\ldots\ldots\quad s-2n-2}.$$

(4.) Proceed in the same manner with the fourth term of the first series, and so on with the others, advancing at each new multiplication one term to the right in the first series. and $n+1$ terms to the left in the second series, until a term is reached in the first series, the exponent of x in which is equal to, or greater than s. The sum of the several products thus obtained will be the value of N. We have therefore

$$\begin{aligned}\mathrm{N}=&\frac{h(h+1)(h+2)\ldots\ldots h+s-1}{1\,.\,2\,.\,3\quad\ldots\ldots\quad s}\\&-\frac{h}{1}\times\frac{h(h+1)(h+2)\ldots\ldots h+s-n-2}{1\,.\,2\,.\,3\quad\ldots\ldots\quad s-n-1}\\&+\frac{h(h-1)}{1\,.\,2}\times\frac{h(h+1)(h+2)\ldots\ldots h+s-2n-3}{1\,.\,2\,.\,3\quad\ldots\ldots\quad s-2n-2}\\&-\&\mathrm{c.}\end{aligned}$$

The series now found for N may be changed into another, having a more elegant form, by reducing all the terms to others having the common denominator $1\,.\,2\,.\,3\ldots\ldots h-1$. This will be accomplished by leaving out of the numerator and denominator of the first term all the numbers after $h-1$ to s, (including s), when s is greater than $h-1$, or by inserting the numbers between s and $h-1$ (the last included), when $s \angle h-1$; by leaving out of the numerator and denominator of the second term all the numbers from $h-1$ to $s-n$, or by inserting those numbers; and so on with the other terms. If we then make the common denominator $1\,.\,2\,.\,3\ldots h-1=k$, we shall have

$$\begin{aligned}\mathrm{N}=&\frac{1}{k}(s+1)(s+2)(s+3)\ldots\ldots(s+h-1)\\&-\frac{h}{k}(s-n)(s-n+1)\ldots\ldots(s-n+h-2)\\&+\frac{h(h-1)}{1\,.\,2k}(s-2n-1)(s-2n)\ldots\ldots(s-2n+h-3)\\&-\&\mathrm{c.}\end{aligned}$$

to be continued till the last factor of one of the terms becomes 0 or negative. If we also make

$$\begin{aligned}&s+h-1=f\\&s-n+h-2=f-(n+1)=f'\\&s-2n+h-3=f-2(n+1)=f''\\&s-3n+h-4=f-3(n+1)=f'''\\&\&\mathrm{c.}\end{aligned}$$

and write the factors in each of the terms in the reverse order, the above value of N will become

$$\begin{aligned}\mathrm{N}=&+f(f-1)(f-2)\ldots\ldots(f-h+2)\frac{1}{k}\\&-f'(f'-1)(f'-2)\ldots\ldots(f'-h+2)\frac{h}{k}\\&+f''(f''-1)(f''-2)\ldots\ldots(f''-h+2)\frac{h(h-1)}{1\,.\,2k}\\&-f'''(f'''-1)(f'''-2)\ldots\ldots(f'''-h+2)\frac{h(h-1)(h-2)}{1\,.\,2\,.\,3k}\\&+\&\mathrm{c.}\end{aligned}$$

21. As an example of the application of this formula, let it be required to assign the probability of throwing the point 16 with 4 common dice. (Simpson, p. 53.)

A die having no face marked 0, it is necessary, in order to adopt the formula to this case, to suppose the number of points on each face to be diminished by unit, which is equivalent to supposing $s-h$ to be substituted for s. The numbers are then 0, 1, 2, 3, 4, 5, and we have $n=5$, $h=4$, and $s=(16-4)=12$. Hence

$$\begin{aligned}&f=s+h-1=15\\&f'=f-(n+1)=9\\&f''=f-2(n+1)=3\\&f'''=f-3(n+1)=-3,\end{aligned}$$

and $k=1\,.\,2\,.\,3$. Substituting these values in the formula, we find

$$\begin{aligned}\mathrm{N}=&15\,.\,14\,.\,13\times\frac{1}{6}(=+455)\\&-9\,.\,8\,.\,7\times\frac{4}{6}(=-336)\\&+3\,.\,2\,.\,1\times\frac{4\,.\,3}{1\,.\,2\,.\,6}(=+6)\end{aligned}$$

or $\mathrm{N}=125$. Now the probability of the event is $\mathrm{N}\div(n+1)^h$; and in the present case $(n+1)^h=6^4=1296$; consequently the probability required, namely that of throwing the point 16 with 4 dice, is $\frac{125}{1296}$.

22. In the numerical solution of questions of this sort, it sometimes happens that the labour may be abridged by computing the probability of throwing a different point from that which is proposed, but which has the same number of chances in its favour. For example, let it be proposed to determine the probability that in throwing 10 dice the sum of the points will be 50. In this case, the smallest number of points that can possibly be thrown is 10, and the greatest 60; and the chances in favour of throwing 10 and of throwing 60 are obviously equal. The probability of throwing any given number of points above 10 is also evidently the same as that of throwing the number which is as much under 60; and consequently the probability of throwing 50 is the same as the probability of throwing 20, these numbers being at equal distances from the extremes. Now to find the probability of throwing 20 with 10 dice, or, which is the same, the probability that in 10 successive drawings from an urn containing 6 balls, marked with the numbers 0, 1, 2, 3, 4, 5, the sum of the numbers drawn will be 10, we have $h=10$, $n=5$, $s=10$; whence $f=19$, $f'=13$, $f''=7$, f''' negative, and $k=1\,.\,2\ldots9$. Substituting these numbers in the series for N, and observing that since $f''-h+2=-1$, the third term becomes negative, we have

$$\begin{aligned}\mathrm{N}=&\frac{19\,.\,18\,.\,17\,.\,16\,.\,15\,.\,14\,.\,13\,.\,12\,.\,11}{1\,.\,2\,.\,3\,.\,4\,.\,5\,.\,6\,.\,7\,.\,8\,.\,9}(=92378)\\&-\frac{13\,.\,12\,.\,11\,.\,10\,.\,9\,.\,8\,.\,7\,.\,6\,.\,5}{1\,.\,2\,.\,3\,.\,4\,.\,5\,.\,6\,.\,7\,.\,8\,.\,9}(=-7150),\end{aligned}$$

and consequently $\mathrm{N}=85228$. Dividing this by $(n+1)^h=6^{10}=60466176$, the probability of throwing 20, or of throwing 50, with 10 dice is found $=\frac{85228}{60466176}$, or between $\frac{1}{709}$ and $\frac{1}{710}$.

23. The probability that the whole number of points drawn in h trials will *not exceed* s is found by substituting for s the different values 0, 1, 2……s in the series for N, and taking the sum of the results. This labour, however, may be avoided by means of a property of the figurate numbers. It is well known that the sum of the series of numbers obtained by giving n every value from $n=1$ to $n=v$ (v being any number whatever) in the formula

$$\frac{n(n+1)(n+2)\ldots\ldots(n+u)}{1\cdot 2\cdot 3\ \ldots\ldots\ u+1}$$

is expressed by this other formula

$$\frac{v(v+1)(v+2)\ldots\ldots(v+u)(v+u+1)}{1\,.\,2\,.\,3\ \ldots\ldots(u+1)(u+2)};$$

or, which is the same thing, that the sum of the series obtained by giving x successively every value from $x=1+u$ to $x=1+u+v$ in the formula

$$\frac{x(x-1)(x-2)\ldots\ldots(x-u)}{1\,.\,2\,.\,3\qquad u+1}$$

is expressed by this other formula

$$\frac{(x+1)x(x-1)\ldots\ldots x-u}{1\,.\,2\,.\,3\ldots\ldots\ldots u+2},$$

in which $x=1+u+v$.

Comparing the different terms of the series for N (20) with these last formulæ, it will be evident, that on giving s every value successively, from 0 to s in the value of f, and denoting by N′ the sum of all the results, we shall have

$$N'=+\frac{(f+1)f(f-1)(f-2)\ldots(f-h+2)}{1\,.\,2\,.\,3\,.\,4\quad\ldots\quad h}$$
$$-\frac{(f'+1)f'(f'-1)(f'-2)\ldots(f'-h+2)}{1\,.\,2\,.\,3\,.\,4\quad\ldots\quad h}\times h$$
$$+\frac{(f''+1)f''(f''-1)(f''-2)\ldots(f''-h+2)}{1\,.\,2\,.\,3\,.\,4\quad\ldots\quad h}\times\frac{h(h-1)}{1\,.\,2}$$
$$-\&c.$$

for the probability that the number of points thrown will not be greater than s.

As an example, let $h=10$, $s=5$, $n=5$; we have then $f=s+h-1=14$, $f'=f-(n+1)=8$, whence $f'-h+2=0$, and consequently the second term vanishes. Hence

$$N'=\frac{15\,.\,14\,.\,13\,.\,12\,.\,11\,.\,10\,.\,9\,.\,8\,.\,7\,.\,6}{1\,.\,2\,.\,3\,.\,4\,.\,5\,.\,6\,.\,7\,.\,8\,.\,9\,.\,10}=3003.$$

The probability, therefore, of the sum of the numbers drawn in 10 drawings not exceeding 5, is $3003\div(6)^{10}$, or $\frac{3003}{60466176}$. And this is also the probability that in throwing 10 common dice the sum of the points does not exceed 16. (Simpson, p. 60.)

24. In the preceding questions the number of trials, denoted by h, has been supposed to be given; and the object, in every case, has been to determine the value of a given term, or of a given number of terms of the series produced by the development of the binomial $(p+q)^h$. But there is a numerous class of questions in respect of which the exponent h is unknown, and is required to be determined from the condition that an assigned term, or the sum of a certain number of assigned terms of the development, must have a given value. For example, let it be proposed to determine how often a common die must be thrown in order to give the probability of ace turning up *once at least*, equal to a given fraction u. Here the probability of throwing ace in any throw being $\frac{1}{6}$, we have $p=\frac{1}{6}$, and $q=\frac{5}{6}$. Now, as every term of the development of $(p+q)^h$, excepting the last, gives a combination in which ace occurs once or oftener, the question requires a value to be found for h, such, that the sum of the first h terms of that development, shall be equal to u. This may be done, in general, by the common methods of trial and error; but in the present case, the last term being the only one not included among those which contain a chance of throwing ace, it is evident that it is only necessary to find the last term alone in order to have the probability of *not* throwing ace in h trials, which by the question is $1-u$. The last term of the development is q^h; therefore we must have the equation $q^h=1-u$; whence $h \log q=\log(1-u)$, and $h=\log(1-u)\div\log q$. Let $1-u=\frac{\beta}{\gamma}$ and $q=\frac{b}{c}$, we shall then have $\log(1-u)=\log\beta-\log\gamma$, and $\log q=\log b-\log c$; whence

$$h=\frac{\log\beta-\log\gamma}{\log b-\log c}.$$

Substituting in this general formula the particular numbers given in the question, namely $b=5$, $c=6$; and supposing $u=\frac{1}{2}$, and consequently $\beta=1$, $\gamma=2$, we have $h=\frac{\log 2}{\log 6-\log 5}$; whence, by computing from the logarithmic tables, $h=3{\cdot}8$. From this it follows, that in four trials the probability of throwing ace once at least, is greater than the probability of not throwing it at all.

If the question had been to determine in how many throws with two dice one may undertake, on an equality of chance, to throw aces at least once, we should have had $p=\frac{1}{36}$, $q=\frac{35}{36}$, and consequently $b=35$, and $c=36$. Substituting these numbers in the general formula, and observing, that in this case also $\beta=1$, $\gamma=2$, we get $h=\frac{\log 2}{\log 36-\log 35}=24{\cdot}6$. The probability of not throwing aces once is therefore greater than the opposite probability or that of throwing aces once or oftener, when the number of throws is 24, but less when the number is 25.

These two questions are celebrated in the early history of the theory of Probability, from the circumstance that the Chevalier de Méré, by whom they were proposed to Pascal, declared the two results above stated to be inconsistent with each other, and thence took occasion to question the accuracy of the theory of combinations by means of which they had been obtained. He reasoned thus: Since the probability of throwing ace with one die is $\frac{1}{6}$, and that of throwing aces with two dice $\frac{1}{6}$ of $\frac{1}{6}=\frac{1}{36}$; therefore, if there be a given probability in favour of throwing ace in four throws with one die, there must likewise be the same probability of throwing aces with two dice in $6\times4=24$ throws; in other words, the chances in favour of an event E in a single trial, being six times more numerous than those in favour of F, there will be as many chances in favour of F in six trials as there are in favour of E in one. The error consists in supposing that the number of trials must increase or diminish exactly in the inverse ratio of the probability of obtaining the proposed point.[1]

25. The general question may be enunciated as follows: Let p= the probability an event E will happen, q the probability it will fail; how many trials are required to give a probability $=u$ that E will happen k times.

Let x= the number required. Taking the sum of all the terms of the development of $(p+q)^x$ in which the exponent of p is less than k, we shall have the probability that the event does *not* happen k times in x trials. This sum must consequently be made equal to $1-u$; therefore, beginning the last term, and writing the terms in the reverse order, we have the equation

$$q^x+x\,q^{x-1}p+\frac{x\,(x-1)}{1\ldots2}q^{x-2}\,p^2\ldots\ldots$$
$$+\frac{x\,(x-1)\ldots(x-k+2)}{1\,.\,2\ldots\ldots\ldots(k-1)}q^{x-k+1}\,p^{k-1}=1-u.$$

Let $p=e\,q$, and this equation becomes

$$q^x\left\{1+x\,e+\frac{x\,(x-1)}{1\,.\,2}\,e^2\ldots\ldots+\frac{x\,(x-1)\ldots\ldots(x-k+2)}{1\,.\,2\ldots\ldots(k-1)}\,e^{k-1}\right\}$$
$$=1-u$$

from which the value of x may be found by the ordinary methods of converging series.

If $p=q=\frac{1}{2}$, then $e=1$; and if we also suppose $u=\frac{1}{2}$, and consequently $1-u=\frac{1}{2}$, the equation will become

---

[1] Pascal, *Œuvres*, tom. iv. p. 367; Lacroix, *Elémentaire*, p. 36.

$$1+x+\frac{x(x-1)}{1\,.\,2}\ldots+\frac{x(x-1)\ldots x-k+2}{1\,.\,2\ldots\ldots\ldots k-1}=\tfrac{1}{2}(1+1)^x.$$

But the first side of this equation is the expansion of $(1\times 1)^x$ continued to k terms; therefore, since the sum of the first k terms is equal to one-half of the whole series, and the terms of the first half of the series are the same as those of the last, it follows that the whole number of terms must be $2k$. But the whole number of terms in the expansion of $(1+1)^x$ is $x+1$; therefore $2k=x+1$, and $x=2k-1$. Suppose $k=10$, then $x=19$; hence in tossing a shilling it is an even bet that head will turn up 10 times in 19 throws.

SECT. III. OF THE PROBABILITY OF EVENTS DEPENDING ON A REPETITION OF TRIALS, OR COMPOUNDED OF ANY NUMBER OF SIMPLE EVENTS, THE CHANCES IN RESPECT OF WHICH ARE KNOWN *A PRIORI*, AND VARY IN THE DIFFERENT TRIALS.

26. Let us suppose the trials to consist in drawing balls from an urn containing a white balls, and b black balls, and that when a ball is extracted it is not returned to the urn. Make $a+b=c$, and let the extraction of a white ball be the event W, and that of a black ball the event B. At the first trial the probability of W is $\frac{a}{c}$ (4), and that of B, $\frac{b}{c}$. But at the second trial, the number of balls in the urn is diminished by 1; and the probability of drawing a white ball at the second trial is therefore not the same as it was in the first, but is influenced by the event which has already taken place. If W happened at the first trial, the number of white balls remaining in the urn is then $a-1$; the number of black is b, and the number of both colours $c-1$. The probability of W at the next trial is therefore $\frac{a-1}{c-1}$, and that of B is $\frac{b}{c-1}$. In like manner, if B happened at the first trial, the probability of W at the second is $\frac{a}{c-1}$, and that of B is $\frac{b-1}{c-1}$. Hence (7) the different combinations which can arise from two trials are the following:

WW, WB, BW, BB,

the probabilities of which are respectively,

$$\frac{a(a-1)}{c(c-1)},\quad \frac{ab}{c(c-1)},\quad \frac{ba}{c(c-1)},\quad \frac{b(b-1)}{c(c-1)}.$$

Now if we neglect the order of succession in the two cases in which W and B are combined, the probability of the compound event which consists of the extraction of a ball of each colour in the two trials, is $\frac{2ab}{c(c-1)}$, and the probabilities of the three possible combinations are respectively:—

$$\frac{a(a-1)}{c(c-1)},\quad \frac{2ab}{c(c-1)},\quad \frac{b(b-1)}{c(c-1)}.$$

Comparing these with the probabilities of the same combinations when the chances are constant, or the ball is returned to the urn after each drawing, namely

$$\frac{a^2}{c^2},\quad \frac{2ab}{c^2},\quad \frac{b^2}{c^2},$$

the analogy of the two cases is obvious.

After two balls have been drawn, the whole number remaining in the urn is $c-2$; but the number of each colour depends on the two events that have already occurred. If two white balls have been drawn, the probability of drawing a white ball at the next trial will be $\frac{a-2}{c-2}$; but we have just seen that the probability of WW is $\frac{a(a-1)}{c(c-1)}$; therefore (7) the probability of WWW is $\frac{a(a-1)(a-2)}{c(c-1)(c-2)}$. The probability of drawing a black ball after two white have been drawn is $\frac{b}{c-2}$ (for there are now $c-2$ balls in the urn, of which b are white); therefore the probability of WWB is $\frac{a(a-1)b}{c(c-1)(c-2)}$. On forming in this manner all the different possible combinations which can result from three trials, we find

WWW, probability, $=\frac{a(a-1)(a-2)}{c(c-1)(c-2)}$,

WWB, ——— $=\frac{a(a-1)b}{c(c-1)(c-2)}$,

WBW, ——— $=\frac{ab(a-1)}{c(c-1)(c-2)}$,

BWW, ——— $=\frac{ba(a-1)}{c(c-1)(c-2)}$,

BBW, ——— $=\frac{b(b-1)a}{c(c-1)(c-2)}$,

BWB, ——— $=\frac{ba(b-1)}{c(c-1)(c-2)}$,

WBB, ——— $=\frac{ab(b-1)}{c(c-1)(c-2)}$,

BBB, ——— $=\frac{b(b-1)(b-2)}{c(c-1)(c-2)}$.

If we disregard the order of succession in those combinations into which W and B both enter, and consider the occurrence of W twice and B once as the same compound event; and also the occurrence of W once and B twice as the same compound event, in whatever order they occur, the probability of the former will be $\frac{3a(a-1)b}{c(c-1)(c-2)}$, and of the latter $\frac{3ab(b-1)}{c(c-1)(c-2)}$.

27. In general, if $m'+n'$ balls have been drawn, of which m' have been found to be white and n' black, the number of white balls in the urn will now be $a-m'$, the number of black $b-n'$, and the whole number of both colours $c-m'-n'$. Hence the probability of drawing a white ball in the next trial will be $\frac{a-m}{c-m'-n'}$; and that of drawing a black ball $\frac{b-n'}{c-m'-n'}$. Now if in these two fractions we substitute successively for m' and n' all the different numbers from 0 to $m-1$ and $n-1$ respectively, the product of the $m+n$ numbers thus obtained will (7) be the probability of drawing m white balls and n black in an assigned order, in $m+n$ trials Let this probability be denoted by K, and we shall have

$$K=\frac{a(a-1)(a-2)\ldots\ldots(a-m+1)\times b(b-1)(b-2)\ldots\ldots(b-n+1)}{c(c-1)(c-2)\ldots\ldots(c-m-n+1)},$$

whatever the given order may be. Hence, if we denote by P the probability of m white balls and n black being drawn in any order whatever, in h trials, we shall have $P=UK$, where, as in (12), $U=\frac{1\,.\,2\,.\,3\ldots\ldots h}{1\,.\,2\,.\,3\ldots\ldots m\times 1\,.\,2\,.\,3\ldots\ldots n}$ the co-efficient of that term of the binomial $(p+q)^h$ which has for its argument $p^m\,q^n$; this co-efficient expressing all the different arrangements which can be formed of m things of one kind, and n things of another.

28. When the urn is supposed to contain balls of more than two different colours, the probability of any proposed number of each colour being drawn in a given number of trials is found with the same facility. Suppose it to contain a_1 of the first colour, a_2 of the second, a_3 of the third, and so on and let $a_1+a_2+a_3$ &c.$=c$; then the probability that

in $m+n+r+\&c.=h$ trials, there will be drawn m of the first colour, n of the second, r of the third, &c. is

$$\begin{aligned}&U'\times a_1(a_1-1)(a_1-2)\ldots\ldots\ldots(a_1-m+1)\\ &\times a_2(a_2-1)(a_2-2)\ldots\ldots\ldots(a_2-n+1)\\ &\times a_3(a_3-1)(a_3-2)\ldots\ldots\ldots(a_3-r+1)\\ &\times a_4(a_4-1)(a_4-2)\ldots\ldots\ldots(a_4-s+1)\\ &\times \&c.\\ &\div c(c-1)(c-2)\ldots\ldots\ldots(c-h+1)\end{aligned}$$

where, as in (15),

$$U=\frac{1\,.\,2\,.\,3\ldots\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots\ldots m\times 1\,.\,2\,.\,3\ldots\ldots n\times 1\,.\,2\,.\,3\ldots\ldots\, r\times\&c.}.$$

29. The following examples will shew the use of the preceding formulæ.

Suppose a bag to contain 16 balls, of which 8 are white and 8 black, what is the probability that in drawing 8 balls from the bag the whole of them will be white?

Applying the formula (27) to the solution of this question, we have $a=8$, $b=8$, $c=16$, $m=8$, $n=0$, and as the probability required is that of drawing white balls only, b cannot enter into any of the factors of the numerator; hence

$$K=\frac{8\,.\,7\,.\,6\,.\,5\,.\,4\,.\,3\,.\,2\,.\,1}{16\,.\,15\,.\,14\,.\,13\,.\,12\,.\,11\,.\,10\,.\,9}=\frac{1}{12870};$$

and since $m=h$, $U=1$, the probability sought, is therefore $\frac{1}{12870}$.

Let there be a heap of 20 cards, wherein are 7 diamonds, 6 hearts, 4 spades, and 3 clubs; required the probability that in drawing 8 of them at a venture there shall come out 3 diamonds and 2 hearts? (Simpson, p. 21.)

The probability required in this case being that of drawing 3 diamonds, 2 hearts, and 3 other cards which are neither diamonds nor hearts, the spades and clubs may be considered as forming one parcel, containing 7 cards. We have then in the formula (28) $a_1=7$, $a_2=6$, $a_3=7$, $c=20$; $m=3$, $n=2$, $r=3$, $h=8$; therefore

$$U'=\frac{1\,.\,2\,.\,3\,.\,4\,.\,5\,.\,6\,.\,7\,.\,8}{1\,.\,2\,.\,3\times 1\,.\,2\times 1\,.\,2\,.\,3}=560,$$

and the probability required becomes,

$$560\times\frac{7\,.\,6\,.\,5\times 6\,.\,5\times 7\,.\,6\,.\,5}{20\,.\,19\,.\,18\,.\,17\,.\,16\,.\,15\,.\,14\,.\,13}=\frac{1225}{3978}.$$

The odds against the event are therefore 2753 to 1225, or nearly 9 to 4.

Let 4 cards be drawn from a pack of 52; what is the probability of drawing one of each sort?

In this case we have $a_1=13$, $a_2=13$, $a_3=13$, $a_4=13$, $c=52$; also $m=1$, $n=1$, $r=1$, $s=1$, $h=4$, whence $U'=\frac{1\,.\,2\,.\,3\,.\,4}{1\,.\,1\,.\,1\,.\,1}=24$, and the probability required becomes, on substituting these numbers in the formula (28),

$$24\times\frac{13\,.\,13\,.\,13\,.\,13}{52\,.\,51\,.\,50\,.\,49}=\frac{2197}{20825}=\frac{1}{9}\text{ nearly.}$$

The odds against this event are nearly 8 to 1.

30. The following question, proposed by Huygens, and solved by Demoivre and Bernoulli (*Ars Conjectandi*, p. 59), belongs to the class of problems now under consideration.

An urn contains 12 balls, of which 4 are white and 8 black. Three gamesters A, B, and C agree that the first who, blindfold, shall draw a white ball shall be the winner of the stakes. They also agree that A shall draw first, B second, C third, A fourth, and so on; and the balls drawn are not replaced in the urn. It is proposed to find their respective probabilities of winning.

Here the play terminates as soon as a white ball is drawn, and it must therefore terminate with the 9th trial, if not sooner, inasmuch as, after 8 black balls have been drawn, the urn will contain only white balls, and the probability of drawing a white ball at the next trial will become certainty. The question will therefore be solved, if we determine the probabilities of the play ending with the 1st, 2d, 3d, 4th, &c. games respectively, and take the sum of the probabilities of its ending with the 1st, 4th, and 7th, for the probability of A's winning; the sum of the probabilities of its ending with the 2d, 5th, and 8th, for the probability of B's winning; and the sum of the probabilities of its ending with the 3d, 6th, and 9th, for the probability of C's winning.

For the sake of rendering the solution more general, let a be the number of white balls in the urn, b the number of black, and let $a+b=c$. The probability of drawing a white ball at the first trial, or of the play ending with the first trial, is then $\frac{a}{c}$.

The probability of the play ending with the second trial is compounded of the probability of a black ball being drawn at the first trial, and a white at the second; and the probability of both events (26) is $\frac{ba}{c(c-1)}$.

The probability of the play ending with the third trial is compounded of three separate probabilities, namely, that a black ball will be drawn at the first trial; that a black ball will be drawn at the second; that a white ball will be drawn at the third;—and the probability of the concourse of these events (26) is $\frac{b(b-1)a}{c(c-1)(c-2)}$.

In general the probability of a black ball being drawn in $x-1$ trials successively, and a white ball at the xth is $\frac{b(b-1)(b-2)\ldots\ldots(b-x+2)a}{c(c-1)(c-2)\ldots\ldots\;(c-x+1}$. Substituting for a, b, and c in this formula the numbers proposed by Huygens, we obtain in respect of the 1st, 4th, and 7th trials, or the probability in favour of A,

$$\frac{4}{12}+\frac{8\,.\,7\,.\,6}{12\,.\,11\,.\,10}\cdot\frac{4}{9}+\frac{8\,.\,7\,.\,6\,.\,5\,.\,4\,.\,3}{12\,.\,11\,.\,10\,.\,9\,.\,8\,.\,7}\cdot\frac{4}{6}=\frac{77}{165};$$

in respect of the 2d, 5th, and 8th trials, or the probability in favour of B,

$$\frac{8}{12}\cdot\frac{4}{11}+\frac{8\,.\,7\,.\,6\,.\,5}{12\,.\,11\,.\,10\,.\,9}\cdot\frac{4}{8}+\frac{8\,.\,7\,.\,6\,.\,5\,.\,4\,.\,3\,.\,2}{12\,.\,11\,.\,10\,.\,9\,.\,8\,.\,7\,.\,6}\cdot\frac{4}{5}=\frac{53}{165},$$

and in respect of the 3d, 6th, and 9th trials, or the probability in favour of C,

$$\frac{8\,.\,7}{12\,.\,11}\cdot\frac{4}{10}+\frac{8\,.\,7\,.\,6\,.\,5\,.\,4}{12\,.\,11\,.\,10\,.\,9\,.\,8}\cdot\frac{4}{7}+\frac{8\,.\,7\,.\,6\,.\,5\,.\,4\,.\,3\,.\,2\,.\,1}{12\,.\,11\,.\,10\,.\,9\,.\,8\,.\,7\,.\,6\,.\,5}\cdot\frac{4}{4}=\frac{35}{165}.$$

The chances in favour of A, B, and C, are therefore proportional to the numbers 77, 53, 35, respectively.

If the condition of the play had been that the ball was to be returned to the urn after each trial, the chances in favour of the three gamesters would have been easily found by the formula (12) to be respectively as the numbers 9, 6, and 4.

SECT. IV. OF MATHEMATICAL AND MORAL EXPECTATION.

31. In the theory of probability, the term *expectation* is used to denote the product found by multiplying the value of a casual benefit into the probability of the event on which it is contingent taking place. But the value of a benefit may be estimated either with respect to its absolute amount, or to the amount of relative advantage it affords the individual who receives it. This consideration has led to a distinction between mathematical and moral expectation. When we place the circumstances of the individual entirely out of consideration, and have regard merely to the abstract or absolute value of the benefit, the product of its amount by the probability of obtaining it is the *mathematical expec-*

tation of the individual; but when a relative value is assigned to the benefit, the product of this relative value by the probability of obtaining it is called the *moral expectation*, because it is estimated by certain moral considerations respecting the circumstances or fortune of the individual in whose favour the expectation exists, on the principle that a sum of money which may be relatively of very little importance to a man in possession of a large fortune may be of great importance to another who is less favourably circumstanced. We shall first consider the *mathematical expectation*.

32. Suppose A and B to engage in play; let p be the probability of A's winning a game, q the probability of B's winning it, and s a sum of money staked on the issue of the game. By the definition, the mathematical expectation of A is ps, and that of B is qs. Now if we suppose these expectations to be purchased by A and B, the sums they ought respectively to pay for them, or in other words to stake on the issue of the game, must be proportional to their respective expectations, in order that they may play on equal terms. Let therefore a be the sum staked by A, and b the sum staked by B, we have then $ps : qs :: a : b$, and consequently $pb=qa$. Now suppose $a+b=s$, or that the sum played for is the amount of the stakes; then, since b is the sum A expects to gain, and p is the probability of his gaining it, pb is the mathematical value of A's expectation of gain. In like manner qa is the mathematical value of B's expectation of gain. Hence it follows, that when the sum staked by each is proportional to his probability of winning, the mathematical expectations of the two players are equal; so that after the stakes have been placed, and before the event is decided, they might exchange places without advantage or disadvantage to either. It follows likewise, that since the sum which the one must gain is just that which the other must lose, the product qa, which is B's expectation of gain, may be regarded as A's expectation of loss; or (if taken with a negative sign) as part of A's whole expectation, which then becomes $pb-qa$. But $pb-qa=0$; whence the condition of A before the event is decided is not altered by the circumstance of his having staked on the issue of the play.

33. This conclusion at first sight appears paradoxical; for it is certain, that after the stakes are placed, A must either gain the sum b or lose a, and therefore his fortune will of necessity either be increased by the gain of his adversary's stake, or diminished by the loss of his own. The explanation depends on theorems which will afterwards be demonstrated relative to the repetition of trials, from which it results, that though in a single trial the player must either lose or gain, yet on multiplying sufficiently the number of games, a probability will at length be obtained, approaching as nearly to certainty as we please, that the sum gained or lost in the long run will not exceed a certain given fraction (which may be as small as we please) of the whole sum staked, provided the play is undertaken on terms of mathematical equality. But this indefinite repetition of the hazard is practically impossible; and innumerable cases may easily be imagined, in which an individual will be guided by other considerations than the mere mathematical value of the expectation in undertaking or declining a risk. A person of moderate fortune would scarcely be persuaded to risk L.500 for the expectation of gaining L.5, though the chances might be 100 to 1 in favour of the event which would produce that sum; but numbers would be found willing enough to pay L.5 for the expectation of gaining L.500, the chances being 100 to 1 against them. In both cases, however, the expectation would be purchased at its real abstract value. According to the formula of mathematical expectation, the man whose sole fortune consists of a lottery ticket which has an equal chance of turning up a prize of L.20,000 or a blank, is in an equally advantageous position as he who is in possession of L.10,000; yet no man of ordinary prudence, if offered his choice of the two states, would hesitate as to which he ought to give the preference. Common sense will prevent a man from risking a sum, the loss of which would be attended with great privations, even when, mathematically speaking, the chances are considerably in his favour. It is also obvious that two individuals whose fortunes are very unequal cannot engage in play with the same advantage, although the chances in favour of each, in respect of a single game, are precisely the same. The one who has a large fortune can repeat the hazard so often as to obtain a probability almost equal to certainty that his loss will not amount to any given sum; whereas the other, who cannot continue the play in case of loss, runs the risk of being ruined. It is thus evident, that in a multitude of cases the abstract theory of probability is not alone sufficient to give the value of an expectation, and that in dealing with contingent events, an individual must be guided to a certain extent by considerations of relative advantage.

34. Various hypotheses have been imagined for the purpose of reducing such relative or moral considerations to accurate calculation; but that which appears the most natural, and applicable to the greatest number of cases, consists in supposing the relative value of any infinitely small sum to be directly proportional to its absolute value, and inversely as the fortune of the individual who has an expectation of receiving it. This principle was first proposed by Daniel Bernoulli in the *Petersburg Commentaries* (vol. v.), and is there applied by him to the solution of a number of questions of great practical interest.

Let x be the absolute value of the capital, or, as it is denominated by Laplace, the physical fortune, of an individual; then, according to the hypothesis of Bernoulli, the moral advantage which he derives from an infinitely small increment of fortune $=dx$, is measured by the expression $c\frac{dx}{x}$, c being a constant to be determined by the nature of the question. Now, if we suppose the physical fortune to arise from the accumulation of the elements dx, and denote by y the relative or *moral value* of the fortune, of which the absolute or physical value is x, we shall have

$$y=\int c\frac{dx}{x}=c\ \text{log.}\ x+\text{constant}.$$

To determine the constant, we may suppose $y=o$, when x has a given value $=a$; this gives $o=c\ \text{log.}\ a+\text{constant}$, whence $y=c\ (\text{log.}\ x-\text{log.}\ a)$, or $y=c\ \text{log.}\ \frac{x}{a}$; and it is to be observed, that those values of x and y can never become negative, for as Bernoulli has remarked, it is only the person who is dying of hunger that can be said to possess absolutely nothing. In every other circumstance the mere possession of existence may be accounted a moral advantage, to which, however, it would be absurd to attempt to assign a numerical value.

35. From the above formula, it is easy to deduce a numerical expression for the value of a moral expectation. Let a be the original fortune of the individual, and α, β, γ, &c. sums to be received on the occurrence of certain contingent events, E, F, G, &c. This being supposed, if the event E happens, the absolute fortune of the individual becomes $a+\alpha$, and its relative value, therefore, according to the formula, is $c\ \text{log.}\ \frac{a+\alpha}{a}$. If F happens, his absolute fortune becomes $a+\beta$, to which the corresponding relative value is $c\ \text{log.}\ \frac{a+\beta}{a}$; and so on. Now, let the probabilities of the events E, F, G, &c. be respectively p, q, r, &c. (assuming $p+q+r+$ &c.$=1$, so that one or other of the events will necessarily happen), and let Y represent the relative fortune of the individual arising from his expectation, then, since the

value of a benefit in expectation is equal to the amount of the benefit multiplied by the probability of obtaining it, we have

$$Y=c\left\{p \log.\frac{a+\alpha}{a}+q \log.\frac{a+\beta}{a}+r \log.\frac{a+\gamma}{a}+\&c.\right\}$$

Let also X denote the absolute value of Y; then, by the formula, we have $Y=c \log.\frac{X}{a}$. On comparing these two values of Y, we get

$$\log.\frac{X}{a}=p\log.\frac{a+\alpha}{a}+q \log.\frac{a+\beta}{a}+r \log.\frac{a+\gamma}{a}+\&c.;$$

and on passing to numbers,

$$\frac{X}{a}=\frac{(a+\alpha)^p(a+\beta)^q(a+\gamma)^r,\&c.}{a^{p+q+r+\&c.}},$$

therefore, since $p+q+r+\&c.=1$,

$$X=(a+\alpha)^p(a+\beta)^q(a+\gamma)^r, \&c.$$

In this expression X denotes the absolute value of the original fortune and of the expectation added together; if, therefore, we deduct a from X, the difference will be the value of the expectation, or the sum which, if it were to be received certainly, would procure the individual the same relative advantage as his expectation.

36. If the sums α, β, γ, &c. are supposed to be very small in comparison of a, so that quantities of the order $\left(\frac{\alpha}{a}\right)^2$ may be neglected, the preceding equation becomes

$$X=a^{p+q+r+\&c.}+a^{p+q+r\&c.-1}\left\{p\alpha+q\beta+r\gamma+\&c.\right\}$$

whence, since $p+q+r+\&c.=1$,

$$X=a+p\alpha+q\beta+r\gamma+\&c.$$

Deducting from this the original fortune a, the remainder $p\alpha+q\beta+r\gamma+\&c.$ is the value of the expectation, or the sum equivalent to the moral advantage. But the value of the mathematical expectation of the benefits α, β, γ, &c. of which the probabilities are respectively p, q, r, &c. is also $p\alpha+q\beta+r\gamma+\&c.$ (31), therefore, when the contingent benefits are very small in comparison of the original fortune, the moral advantage and the mathematical expectation are sensibly the same.

37 From the formula $X=(a+\alpha)^p(a+\beta)^q(a+\gamma)^r$ &c. Bernoulli deduces the consequence that gambling or betting is attended with a moral disadvantage, even when the chances of gain or loss, mathematically speaking, are perfectly equal. To shew this, he proposes the following question. A, whose fortune is 100 crowns, bets 50 crowns with B, on the issue of an event of which the probability is $\frac{1}{2}$, on these terms: if the event happens, A is to receive from B 50 crowns; if it fails, he is to pay B 50 crowns; what is the relative value of A's fortune, after undertaking the bet, and before the event is decided? In this case, we have $a=100$, $\alpha=50$, $\beta=-50$, $\gamma=0$; also $p=\frac{1}{2}$, $q=\frac{1}{2}$, $r=0$; and the formula (35) becomes

$$X=(100+50)^{\frac{1}{2}}\times(100-50)^{\frac{1}{2}},$$

whence $X=\sqrt{150\times 50}=87$; and, consequently, the condition of A is worse by 13 crowns than it was before he hazarded the bet. The moral disadvantage is therefore equivalent to this sum, though the terms of the play, according to the mathematical theory, are equal.

38. The conclusion arrived at in this particular case is easily shewn to be universally true. Let a be the capital of the player, p his probability of winning, q his probability of losing, and s the sum at stake. In order that he may play on terms of mathematical equality, the part of the stakes contributed by himself, or the sum which he can lose, must be ps (32), and the part contributed by his adversary, or that which he may gain, must be qs. The equation in (35) therefore becomes

$$X=(a+qs)^p\times(a-ps)^q,$$

and if it can be shewn that this value of X is less than a, it will follow that his condition is rendered worse in consequence of having staked on the game. Now, dividing by a, and taking the logarithm of both sides of the equation, we get $\log.\frac{X}{a}=p \log.\left(1+\frac{qs}{a}\right)+q \log.\left(1-\frac{ps}{a}\right)$, the differential of which (making s variable) is

$$d \log.\frac{X}{a}=pqds\left(\frac{1}{1+\frac{qs}{a}}-\frac{1}{1-\frac{ps}{a}}\right).$$

But the second side of this equation is evidently negative; therefore $d \log. X\div a$ is negative; consequently the logarithm of $X\div a$ is negative, and X must be less than a. In all cases, therefore, the bet, if on even terms, produces a moral disadvantage.

39. Another consequence deduced by Bernoulli from this theory of moral expectation, is, that when property of any kind is exposed to a risk or hazard, it is more advantageous to expose it in parts to several risks independent of each other, than to expose the whole at once to a single risk, although the probability of loss be in both cases precisely the same. To prove this, he takes the following example. A merchant has a capital of L.4000, besides goods of the value of L.8000, which must be transported by sea. The probability of the loss of a vessel in the voyage being $\frac{1}{10}$, let it be proposed to find the value of the moral expectation of the merchant in the case of the goods being embarked in a single vessel, and also in the case of one half being embarked in one vessel and the other half in another. Supposing the merchandise embarked in one ship, the absolute fortune of the merchant will be increased to L.12,000 in the event of the safe arrival of the ship, and will be reduced to L.4000 in the event of its being lost. The probability of the first of these events is $\frac{9}{10}$, and of the second $\frac{1}{10}$; therefore his absolute fortune becomes, in virtue of his expectation,

$$X=(12{,}000)^{\frac{9}{10}}\times(4000)^{\frac{1}{10}},$$

whence X=10751. Deducting his other capital, L.4000, there remains L.6751 for the value of the moral expectation in respect of the venture.

Let us next suppose the merchandise embarked in equal parts in two ships. In this case there are three compound events to be considered, 1st, Both vessels may arrive in safety; the probability of which is $\frac{9}{10}\times\frac{9}{10}=\frac{81}{100}$. 2d, One may arrive in safety and the other be lost; the probability of which, as it may happen in two ways, (11) is $2\times\frac{9}{10}\times\frac{1}{10}=\frac{18}{100}$. 3d, Both may be lost; the probability of which is $\frac{1}{10}\times\frac{1}{10}=\frac{1}{100}$. If the first of these events happen, the capital of the merchant will become L.4000+L.8000=L.12,000; if the second happen it will be L.4000+L.4000=L.8000; and if the third happen it will be only L.4000. With these numbers the formula becomes

$$X=(12{,}000)^{\frac{81}{100}}\times(8000)^{\frac{18}{100}}\times(4000)^{\frac{1}{100}},$$

whence X=11033. Deducting his other capital, which was exposed to no risk, there remains L.7033 for the value of the moral expectation. This sum exceeds the former by L.282; and it is easily found by following the same process of reasoning, that in proportion as the risk is divided among a greater number of ships, the moral expectation is increased, and approaches its limit, which is the value of the mathematical expectation, or $\frac{9}{10}$ of L.8000=L.7200.

40. The theory of moral expectation enables us likewise to assign the circumstances in which it is advantageous or

otherwise, to insure property against particular hazards. There are three principal questions to be considered in reference to this subject; 1. The amount of premium the insured may pay without disadvantage, 2. The ratio of his fortune to the value of the sum exposed to risk, in order that it may be advantageous to insure at a given premium; and 3. The capital which the insurer or underwriter ought to possess, in order that he may insure a given risk with probable advantage to himself, and safety to the insured.

Let s be the value of a cargo which a merchant embarks in a ship, p the probability of the safe arrival of the vessel, and a his capital independently of s. The mathematical value of the premium for insurance is qs; for, if we denote the premium by y, then y is the sum the insurer will gain if the vessel reaches its destination in safety, and $s-y$ is the sum he will lose if it does not; and by the theorem for the mathematical expectation $py=q(s-y)$; whence, since $p+q=1$, $y=qs$. If, therefore, the merchant insures the cargo, his absolute fortune becomes $a+s-qs=a+ps$; and if he does not insure, it is the value of X in the equation $X=(a+s)^p a^q$. Hence it will be advantageous or otherwise to insure according as $a+ps$ is greater or less than $(a+s)^p a^q$. Now the logarithm of the first of these expressions, or $\log(a+ps)$, is equivalent to the integral $\int\frac{pds}{a+ps}$; and the logarithm of the second, or $p\log(a+s)+q\log a$, is equivalent to $\int\frac{pds}{a+s}$; but since p is a proper fraction, $a+ps$ is less than $a+s$, and therefore the first integral is greater than the second. Consequently $a+ps$ is, in general, greater than $(a+s)^p a^q$, and the insurance is attended with advantage. Let us now assume $x=a+ps-(a+s)^p a^q$, and x will be the sum the merchant could afford to pay the insurer above the mathematical value of the risk without moral disadvantage. If he pays less than $qs+x$, his relative fortune is increased by insuring; and if he pays more he is a loser. In practice the premium may be considered as less than $qs+x$, but greater than qs; so that while the insured pays more than the mathematical value of the risk, he gains a moral advantage by the transaction.

To solve the second question, let e be the premium demanded for insuring the amount s; then, the other capital of the merchant being a, his fortune after being insured is $a+s-e$; while if he takes the risk on himself, its value becomes $(a+s)^p a^q$. If, therefore, the value of a be determined from the equation $a+s-e=(a+s)^p a^q$, we shall have the amount of capital he ought to possess in order that it may be *morally* a matter of indifference to him whether he insures or not. As an example, let the value of the merchandise, or s, be L.10,000, $e=$L.800, and $p=\frac{19}{20}$. The equation then becomes

$$a+9200=(a+10,000)^{\frac{19}{20}}a^{\frac{1}{20}};$$

whence a is found by approximation $=5043$. It follows, therefore, that unless his other capital amount to L.5043, it would be disadvantageous to neglect insuring, although the premium demanded exceed the mathematical value of the risk (which is $\frac{1}{20}\times$ L.10,000$=$L.500) by L.300.

The third question, the amount of capital the underwriter ought to possess, is determined precisely in the same way. Let b be his capital. After accepting the risk of the sum s for the premium e, his capital will become $b+e$ in the case of the vessel arriving in safety, and $b-s+e$ in the case of its being lost. The formula of the moral expectation therefore becomes $X=(b+e)^p(b-s+e)^q$; and in order that there may be neither advantage nor disadvantage in undertaking the risk, this value of X must be equal to his original capital, b. Supposing, therefore, s, e, p, q, to have the same significations as above, the equation from which b is to be determined is $b=(b+800)^{\frac{19}{20}}(b-9200)^{\frac{1}{20}}$, whence $b=14243$. Unless, therefore, the capital of the insurer amounts to L.14,243, there would be a moral disadvantage in undertaking the risk of insuring a cargo worth L.10,000 for a premium of L.800; and it is easy to see, that if a smaller premium were demanded, the capital ought to be still greater. On making $e=600$, (which still exceeds the mathematical value of the risk), the value of b becomes L.29,878. Hence it follows, that a company possessing a large capital may not only with safety engage in speculations which might prove ruinous to another whose resources are more limited, but even derive from them a sure profit.[1]

41. The theory of moral expectation which we have now been considering had its origin in a problem proposed by Nicolas Bernoulli to Montmort, which, from its having been discussed at great length by Daniel Bernoulli in the *Petersburg Memoirs*, has been usually called the Petersburg problem. It is this; A and B play at heads and tails. A agrees to pay B 2 crowns if head turn up at the first throw; 4 crowns if it turn up at the second, and not before; 8 if it turn up at the third, and not before; and, in general, 2^n crowns if it turn up at the nth throw, and not before: required the value of B's expectation? Here the probability of head turning up at the first throw is $\frac{1}{2}$; the probability of its turning up at the second, and not at the first, is $\frac{1}{2}\times\frac{1}{2}=\frac{1}{4}$; the probability of its not turning up either at the first or second, and of its turning up at the third, $\frac{1}{2}\times\frac{1}{2}\times\frac{1}{2}=\frac{1}{8}$, and so on. Hence the probabilities of B receiving 2, 4, 8, 16......2^n crowns are respectively $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}\cdots\cdots\frac{1}{2^n}$, consequently (31) the mathematical value of B's expectation is

$$\frac{1}{2}\times 2+\frac{1}{4}\times 4+\frac{1}{8}\times 8+\frac{1}{16}\times 16\ldots+\frac{1}{2^n}\times 2^n \text{ crowns.}$$

Now, as no limit can be assigned to n, inasmuch as it is possible that head may not turn up till after a very great, or any assignable number, of throws, this series, of which each term is unity, may go on for ever, and consequently the value of B's expectation becomes infinite. Yet it is obvious that no one would pay any considerable sum for the expectation. This disagreement between the dictates of common sense and the results of the mathematical theory, appeared to Montmort to involve a great paradox; although the question differs in this respect from no other question of chances in which the contingent benefit is very great, and the probability of receiving it very small. If the play could be repeated an infinite number of times, B might undertake to pay without disadvantage any sum, however large, for his expectation. A result, however, more in accordance with ordinary notions, is obtained from the principle of Bernoulli. Let a be the amount of B's fortune before the play begins, x the value of his expectation, or the sum he pays A in consideration of the agreement, and make $z=a-x$. If head turn up at the first throw, B's fortune becomes $z+2$; if at the second, and not before, $z+2^2$; if at the third, and not before, $z+2^3$; and so on. But the probabilities of these events being respectively $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}\cdots\cdots\frac{1}{2^n}$, the formula for the moral expectation becomes (35)

$$X=(z+2)^{\frac{1}{2}}(z+2^2)^{\frac{1}{4}}(z+2^3)^{\frac{1}{8}}\ldots\ (z+2^n)^{\frac{1}{2^n}}.$$

Now the sum which B ought to pay will be determined by making the value of his moral expectation, after the bet, and before the play begins, equal to his previous fortune; we have therefore $a=X$, that is,

$$a=(z+2)^{\frac{1}{2}}(z+2^2)^{\frac{1}{4}}(z+2^3)^{\frac{1}{8}}\ldots\ldots$$

---

[1] See the *Commentarii Acad. Petropolitanæ*, tom. v.; Laplace, *Théorie des Prob.* p. 432; Lacroix, *Traité Elémentaire*, p. 132.

The general term of this series being $(z+2^n)^{\frac{1}{2^n}}=2^{\frac{n}{2^n}}\left(1+\frac{z}{2^n}\right)^{\frac{1}{2^n}}$, the equation may be put under the form

$$a=(2^{\frac{1}{2}}+2^{\frac{2}{4}}+2^{\frac{3}{8}}+2^{\frac{4}{16}}\ldots.)\times\left(1+\frac{z}{2}\right)^{\frac{1}{2}}\left(1+\frac{z}{4}\right)^{\frac{1}{4}}\left(1+\frac{z}{8}\right)^{\frac{1}{8}}\ldots;$$

and since the logarithm of the first factor of this expression is $\left(\frac{1}{2}+\frac{2}{4}+\frac{3}{8}+\frac{4}{16}+\text{\&c.}\right)\log 2$, or $=\frac{1}{2}\left\{1+2\left(\frac{1}{2}\right)+3\left(\frac{1}{2}\right)^2+4\left(\frac{1}{2}\right)^3+\text{\&c.}\right\}\log 2=\frac{1}{2}\left(1-\frac{1}{2}\right)^{-2}\log 2=2\log 2$, we have $\log a=2\log 2+\frac{1}{2}\log\left(1+\frac{z}{2}\right)+\frac{1}{4}\log\left(1+\frac{z}{4}\right)+\frac{1}{8}\log\left(1+\frac{z}{8}\right)+\text{\&c.}$ from which a value of z may be found by trial and error for any given value of a. Suppose $z=100$; on computing the first 10 terms of the series there results $a=107{\cdot}89$, whence (since $x=a-z$) $x=7{\cdot}89$; that is to say, if B possessed only 100 crowns before beginning the play, it would be morally disadvantageous for him to risk 8 crowns for the expectation, although its mathematical value be infinitely great. If we suppose $z=1000$, the sum of 11 terms gives $a=1011$, nearly; so that if B possessed a fortune of 1011 crowns, the value of the moral expectation would, to him, be about 11 crowns.

It is scarcely necessary to remark, that the results deduced from the principle of Bernoulli are of a character widely different from those which are calculated according to the mathematical expectation. The latter gives the precise value of a contingent benefit, without any assumption or hypothesis respecting the personal circumstances of the individual who may gain or lose it; whereas the considerations of relative advantage, of which it is the object of Bernoulli's theory to take account, are entirely arbitrary, and by their very nature incapable of being made the subject of accurate computation. It is evidently impossible to have regard to, or appreciate, all the circumstances which may render the same sum of money a more important benefit to one man than to another; and consequently every rule that can be given for the purpose must be liable to numerous exceptions. The principle, however, is thus far valuable, that it gives in the most common cases a plausible and judicious estimate of the value of things which are not susceptible of exact appreciation; and it has the advantage of being readily submitted to analysis. A different principle, proposed by the celebrated naturalist Buffon, consists in making the value itself of a casual benefit, instead of its infinitely small elements, inversely proportional to the fortune of the expectant; but as this hypothesis has seldom been adopted, it is unnecessary to discuss it in this place.

SECT. V.—OF THE PROBABILITY OF FUTURE EVENTS DEDUCED FROM EXPERIENCE.

42. In the preceding part of this article it has been assumed, in every case, that the number of chances favourable and unfavourable to the occurrence of a contingent event is known *a priori*, and consequently, that the probability of the event, or the ratio of the number of favourable cases to the whole number of cases possible, can be absolutely determined. But in numerous applications of the theory of probabilities, and these, generally speaking, by far the most important, the ratio of the chances in favour of an event to those which oppose it is altogether unknown; and we can form no idea of the probability of the event excepting from a comparison of the number of instances in which it has been observed to happen, with the whole number of instances in which it has been observed to happen and fail. In order to assign the probability of a contingent event in such cases, it is necessary to consider all the different causes or combinations of circumstances by which the event could possibly be produced, and to determine its probabilities successively on the hypotheses that each of these causes exists to the exclusion of all the others. The comparative facilities which these hypotheses give to the occurrence of the event which has actually arrived, will then enable us to determine the relative probabilities of the different hypotheses, and consequently their absolute probabilities, since their sum is necessarily equal to unity; and when the probabilities of the different hypotheses, and of the occurrence of the event on each hypothesis, have been determined, the probability of the event occurring in a future trial will be found by the methods already explained.

43. Taking a simple case, let us suppose an urn to contain 4 counters, which are either white or black; that the number of each colour is unknown, but in four successive drawings (the counter drawn being replaced in the urn after each trial) a white counter has been drawn three times, and a black one once; and let it be proposed to assign the probability of drawing a counter of either colour at the next trial.

In the present case three hypotheses may be formed relative to the number of white and black counters in the urn. 1st, The urn may contain 3 white counters and 1 black; 2d, It may contain 2 white and 2 black; 3d, It may contain 1 white and 3 black; for a counter of each colour having been drawn, the other two possible cases, namely, that they are all white or all black, are excluded by the observation. Now, let p_1, p_2, p_3, be the probabilities respectively of drawing a white counter on each hypothesis, and q_1, q_2, q_3, the probabilities of drawing a black. Supposing the first hypothesis to be true, or that the compound event which has been observed was produced by the cause indicated by that hypothesis, we have $p_1=\frac{3}{4}$, $q_1=\frac{1}{4}$; and the probability of the observed event, or that 3 white counters and 1 black would be drawn, (12) is $4p_1^3\,q_1=\frac{27}{64}$. The second hypothesis gives $p_2=\frac{1}{2}$, $q_2=\frac{1}{2}$, whence $4p_2^3\,q_2=\frac{16}{64}$. The third hypothesis gives $p_3=\frac{1}{4}$, $q_3=\frac{3}{4}$, whence $4p_3^3\,q_3=\frac{3}{64}$. The probabilities of the observed compound event, on each of the three hypotheses, are therefore, respectively, $\frac{27}{64}$, $\frac{16}{64}$, $\frac{3}{64}$; and the question now arises, how are the probabilities of the different hypotheses to be estimated? As we have no data, *a priori*, for determining this question, we must assume the probabilities of the different hypotheses to be respectively proportional to the probabilities they severally give of the observed compound event; in other words, we must assume the probability of any hypothesis to be greater or less according as it affords a greater or smaller number of combinations favourable to the event which has been observed to take place. Thus, if C and C_1 be two independent causes from which an observed event E may be supposed to arise, and C furnishes 20 different combinations out of a given number, favourable to the occurrence of E, while C_1 furnishes only 10 such combinations out of the same number, we naturally infer that the probability of the cause C having operated to produce E, is twice as great as the probability that the event was produced by the operation of the cause C_1. Applying this principle to the present example, the probabilities of the three hypotheses are respectively proportional to the three fractions $\frac{27}{64}$, $\frac{16}{64}$, $\frac{3}{64}$, or to the numbers 27, 16, 3; and as no other hypotheses are admissible, the sum of their probabilities must be unity; therefore, making ϖ_1 the probability of the first hypothesis, ϖ_2 that of the second, and ϖ_3 that of the third, we have

$$\varpi_1=\frac{27}{46},\quad \varpi_2=\frac{16}{46},\quad \varpi_3=\frac{3}{46}.$$

44. Having found the probabilities of the different hypotheses, that of drawing a white counter at the next trial

is obtained without difficulty; for according to what was shewn in (9), the probability of this simple event must be equal to the sum of its probabilities relative to the different hypotheses, each multiplied into the probability of the hypothesis itself. Now it has been seen that, on the first hypothesis, the probability of drawing a white ball is $\frac{3}{4}$; on the second $\frac{2}{4}$, and on the third $\frac{1}{4}$; and that the probabilities of the hypotheses are respectively $\frac{27}{46}$, $\frac{16}{46}$, $\frac{3}{46}$; therefore the probability of a white counter being drawn at the next trial is

$$\frac{3}{4}\times\frac{27}{46}+\frac{2}{4}\times\frac{16}{46}+\frac{1}{4}\times\frac{3}{46}=\frac{116}{184}.$$

In like manner, the probability of a black counter being drawn at the next trial is

$$\frac{1}{4}\times\frac{27}{46}+\frac{2}{4}\times\frac{16}{46}+\frac{3}{4}\times\frac{3}{46}=\frac{68}{184};$$

and the sum of these two fractions is unity, as it ought to be, since the counter drawn must necessarily be white or black.

45. The reasoning which has been employed in this particular case is of general application. Let E be an observed event, simple or compound, of which the particular cause is unknown, but which may be ascribed to any one of the n causes, C_1, C_2, C_3,......C_n, which, before the event has happened, are all equally probable, and such that the operation of any one of them excludes that of the others, so that the event E is produced by one of them alone, and not by the joint agency of several of them. Let the probabilities of the observed event E on the hypothesis that it has proceeded from each of those causes be respectively P_1, P_2, P_3,...P_n, so that if the cause, for instance, C_i were the true one, the probability of the event E, previous to the observation, would be P_i; and let the probabilities (as determined by the event) of the existence of the different causes be respectively ϖ_1, ϖ_2, ϖ_3,.........ϖ_n. From the principle laid down in the preceding paragraph, namely, that the probabilities of the different causes or hypotheses are proportional to the probabilities they respectively give of the observed event, we have

$$\varpi_1 : \varpi_2 : \varpi_3 \ldots\ldots : \varpi_n :: P_1 : P_2 : P_3 \ldots\ldots : P_n$$

whence, making $P_1+P_2,+P_3\ldots\ldots+P_n=\Sigma P_i$, and observing that $\varpi_1+\varpi_2+\varpi_3\ldots\ldots+\varpi_n=1$ (since it is assumed that there are no other causes than those specified from which the event could arise), we have

$$\varpi_1=\frac{P_1}{\Sigma P_i},\ \varpi_2=\frac{P_2}{\Sigma P_i},\ \varpi_3=\frac{P_3}{\Sigma P_i},\ldots\ldots\varpi_n=\frac{P_n}{\Sigma P_i},$$

whence it appears that the probability of each hypothesis respecting the cause of the observed event is found by dividing the probability of the event on the supposition that that particular cause alone existed, by the sum of its probabilities in respect of all the causes. Let us now assume the probabilities of a future event E′ (which may be the same with E or different, but depending on the same causes) in respect of the several hypotheses, to be, p_1, p_2, p_3,......p_n; so that if the particular cause C_i be the true one, the probability of E′ is p_i; and let Π be the probability of E′ in respect of all the causes, then by (9), Π will be equal to the sum of the probabilities p_1, p_2, p_3.....p_n relative to the different hypotheses, each multiplied by the probability of the hypothesis; that is to say we shall have

$$\Pi=p_1\varpi_1+p_2\varpi_2+p_3\varpi_3\ldots\ldots+p_n\varpi_n;$$

or $\Pi=\Sigma p_i\varpi_i$, the symbol Σ indicating the sum of all the different values of p and ϖ in respect of the different causes C_1, C_2, C_3,......C_n.

46. It may be worth while to remark that the word cause is not here used in its ordinary acceptation to denote the combination of circumstances, physical or moral, of which the event is a *necessary* consequence. In the sense we have used the term, the cause C is that which gives rise to the determinate probability P, that the event E will happen; but so long as this probability falls short of certainty, its existence also implies that of another probability, $1-P$, that the contrary event F will happen. If we make $P=1$, the existence of the cause C would necessarily involve the occurrence of E; and it is in this particular sense that the word cause is ordinarily used. In the theory of probabilities the causes of events are considered only in reference to the number of chances they afford for the occurrence of those events which they may possibly, but do not necessarily, produce.

47. The following example may serve to illustrate the method of applying the preceding formulæ. An urn contains n balls, which are known to be either white or black. A ball is drawn at random and found to be white; required the probability of drawing a white ball at the next trial?

In this case, the number of hypotheses that may be made respecting the contents of the urn, is n; for we may suppose that it contained one, or two, or any number of white balls from 1 to n, and each of these cases may be considered as a distinct cause of the observed event E. Let these causes or hypotheses be C_1, C_2, C_3,......C_n, and let us suppose the true cause was C_i, or that the urn contained i white balls. On this hypothesis the probability of the observed event E is $\frac{i}{n}$, whence $P_i=\frac{i}{n}$; and therefore, making i successively equal to 1, 2, 3,....n, we have $\Sigma P_i=\frac{1}{n}(1+2+3..+n)$. But the sum of this arithmetical series is $\frac{n(n+1)}{2}$, therefore $\Sigma P_i=\frac{1}{2}(n+1)$, and consequently,

$$\varpi_i=\frac{P_i}{\Sigma P_i}=\frac{2i}{n(n+1)},$$

which is the probability of the assumption that the event proceeded from the cause C_i, or that the urn contained i white balls. If we suppose $i=n$ we have $\varpi_n=\frac{2}{n+1}$ for the probability that all the balls are white; and if we also suppose $n=3$, this becomes $\frac{1}{2}$; whence if an urn contain 3 balls which must be either black or white, and a white ball be drawn at the first trial, it is an even wager, after the trial, that all the balls are white.

48. Having found, from the observed event E, the probabilities of the different hypotheses, we have now to determine the probability Π of the event E′ (the drawing of a white ball) at the next trial. Here two cases present themselves; according as the ball is replaced in the urn, or is not; or in general, according as the law of the chances remains constant during the series of trials or varies.

1st, Let us suppose that the ball has been replaced in the urn. In this case the probability of the event E′, on the hypothesis that the urn contains i white balls, is $\frac{i}{n}$; that is to say $p_i=\frac{i}{n}$. But the probability ϖ_i of this hypothesis, as found above, is $\frac{2i}{n(n+1)}$; therefore $p_i\varpi_i=\frac{2i^2}{n^2(n+1)}$; whence the general formula (45) $\Pi=\Sigma p_i\varpi_i$ becomes $\Pi=\Sigma\frac{2i^2}{n^2(n+1)}=\frac{2}{n^2(n+1)}\Sigma i^2$. Now $\Sigma i^2=\Sigma i(i+1)-\Sigma i$. But by the property of the figurate numbers referred to in (23), the sum of the series of numbers obtained by giving i every value from $i=1$ to $i=n$ in the formula $\frac{n(n+1)}{1\,.\,2}$ is expressed by $\frac{n(n+1)(n+2)}{1\,.\,2\,.\,3}$; therefore $\Sigma i(i+1)=\frac{n(n+1)(n+2)}{3}$.

We have also as above

$$\Sigma i = 1+2+3\ldots\ldots+n = \frac{n(n+1)}{2};$$

consequently,

$$\Sigma i^2 = \frac{n(n+1)(n+2)}{3} - \frac{n(n+1)}{2} = \frac{n(n+1)(2n+1)}{2 \quad 3}$$

and therefore

$$\Pi = \frac{2}{n^2(n+1)} \times \frac{n(n+1)(2n+1)}{2 \ . \ 3} = \frac{2n+1}{3n}.$$

2d, Suppose the ball which has been extracted is not replaced in the urn. In this case, on the hypothesis that the urn at first contained i white balls, the probability of drawing a white ball at the next trial is $\frac{i-1}{n-1}$; that is, $p_i = \frac{i-1}{n-1}$; and the probability of the hypothesis is the same as in the former case, or $\varpi_i = \frac{2i}{n(n+1)}$; therefore $p_i \varpi_i = \frac{2i(i-1)}{(n-1)n(n+1)}$; and consequently $\Pi = \Sigma p_i \varpi_i = \frac{2}{(n-1)n(n+1)} \Sigma i(i-1)$. Now the value of $\Sigma i(i-1)$ will evidently be found by writing $n-1$ for n in the above expression for $\Sigma i(i+1)$; whence $\Sigma i(i-1) = \frac{(n-1)n(n+1)}{3}$, and, therefore, in this case

$$\Pi = \frac{2}{(n-1)n(n+1)} \times \frac{(n-1)n(n+1)}{3} = \frac{2}{3}.$$

When n is a very large number, the ratio of $2n+1$ to $3n$, the value of Π in the former case, does not sensibly differ from $\frac{2}{3}$, and therefore in both cases $\Pi = \frac{2}{3}$. Hence it follows, that if an event, depending on unknown causes, can happen only in one of two ways, and it has been observed to happen once, the odds are two to one in favour of its happening in the same way at the next occurrence.

49. The expression for ϖ in (45) was determined on the supposition that previously to the experiments being made, we are entirely ignorant of the relative numbers of the two sorts of balls in the urn, and have no reason to suppose one hypothesis more probable than another. If, however, we happen to know, previously to the experiment, that the different causes C_1, C_2, C_3, &c. have not all the same number of chances in their favour, or that the probabilities of the different hypotheses have relative values, it becomes necessary to introduce those relative values, in consequence of which ϖ_1, ϖ_2, &c., will receive a modification. Let us conceive a number of urns, each containing balls of two colours, black and white, to be distributed in n groups, A_1, A_2, A_3........A_n, in such a manner that the ratio of the number of white balls to the number of black balls is the same in respect of each urn belonging to the same group, and consequently that the probability of drawing a ball of either colour is the same from whichever urn in the group it may happen to be drawn, but different in respect of the different groups; and let the probabilities of drawing a white ball from each of the different groups be respectively P_1, P_2, P_3,......P_n. Now, let us suppose there are a_1 urns in the group A_1, a_2 in the group A_2, and so on, and let s = the whole number of urns, so that $s = a_1 + a_2 + a_3 \ldots\ldots + a_n$; then, if we make $\frac{a_1}{s} = \lambda_1$, $\frac{a_2}{s} = \lambda_2$, and so on, λ_1 will be the *a priori* probability that a ball drawn from any urn at random, will be drawn from the group A_1; λ_2 the probability it will be drawn from the group A_2; and, in general, λ_i the probability it will be drawn from the group A_i. This being premised, suppose a trial to be made, and that the event E is a white ball; the probability ϖ_i of the hypothesis that the ball was drawn from the group A_i is found as follows. The *a priori* probability of the ball being drawn from the group A_i is λ_i; and if the ball is actually drawn from that group, the probability of its being white is P_i; therefore the probability of both events is $\lambda_i P_i$; and consequently (45), $\varpi_i = \frac{\lambda_i P_i}{\Sigma \lambda_i P_i}$, the symbol of summation Σ extending to all the values of i from $i=1$ to $i=n$.

50. In the applications of the theory to physical or moral events, the different groups of urns here imagined may be regarded as so many independent causes C_1, C_2, C_3, &c. by any one of which the event E might have been produced; ϖ_i is the probability that the event was produced by the particular cause C_i; P_i is the probability that the cause C_i if it had alone existed, would have produced the observed event E; and λ_i is the probability, previously to the experiment, that C_i would be the efficient cause. The formula $\varpi_i = \frac{\lambda_i P_i}{\Sigma \lambda_i P_i}$, therefore, shews that the probability of any one of the possible causes (C_i) of an observed event is equal to the product of the probability (P_i) of the event taking place if that cause acted alone multiplied into the probability λ_i that the cause C_i is the true one, and divided by the sum ($\Sigma \lambda_i P_i$) of all the similar products formed relatively to each of the causes from which the event can be supposed to arise.

51. The formulæ now obtained can only be used when the number of hypotheses is finite; but in the applications of the theory it most frequently happens that an infinite number of hypotheses may be made respecting the causes of an observed event, as would be the case in the above example if the number of balls in the urn had been unknown. In such cases, in order to find the values of ϖ and Π, it becomes necessary to transform the sums Σ into definite integrals, which is accomplished by means of the theorem $\Sigma X = \int_0^1 X\, dx$, where X is a function of x. Suppose a ball to have been drawn a great number of times in succession from an urn (the number in which is unknown) and replaced in the urn after each drawing, and that the result has been a white ball m times and a black ball n times, the probable constitution of the urn, and thence the probability of drawing a white ball at a future trial will be found as follows. Assume the hypothesis that the ratio of the number of white balls to the whole number in the urn is $x : 1$, and let ϖ be the probability of the hypothesis. On this hypothesis the probability of drawing a white ball in any trial is x, and that of drawing a black ball $1-x$, and consequently, the probability of drawing m white and n black in $m+n$ trials is $Ux^m(1-x)^n$ by (12). We have therefore for the probability of the observed compound event $P = Ux^m(1-x)^n$; whence in consequence of the above formula for transforming a sum into a definite integral $\Sigma P = U\int_0^1 x^m(1-x)^n\, dx$ (U being independent of x) and therefore

$$\varpi = \frac{P}{\Sigma P} = \frac{x^m(1-x)^n}{\int_0^1 x^m(1-x)^n\, dx}.$$

The value of the integral in the denominator of this fraction is obtained by the usual method of integrating by parts. Since

$$d\,\frac{x^{m+1}(1-x)^n}{m+1} = x^m(1-x)^n dx - \frac{n}{m+1}\, x^{m+1}(1-x)^{n-1} dx,$$

therefore

$$\int x^m(1-x)^n dx = \frac{x^{m+1}(1-x)^n}{m+1} + \frac{n}{m+1}\int x^{m+1}(1-x)^{n-1} dx,$$

In like manner we get $\int x^{m+1}(1-x)^{n-1} dx$

$$= \frac{x^{m+2}(1-x)^{n-1}}{m+2} + \frac{n-1}{m+2}\int x^{m+2}(1-x)^{n-2} dx.$$

Continuing this operation n times, or till the exponent of $(1-x)$ becomes $n-n=0$, the last integral will be

$$\int x^{m+n}dx=\frac{x^{m+n+1}}{m+n+1};$$

therefore, collecting the several terms into one sum, we have

$$\int x^m(1-x)^n dx=\frac{x^{m+1}(1-x)^n}{m+1}+\frac{nx^{m+2}(1-x)^{n-1}}{(m+1)(m+2)}\cdots\cdots\cdots$$
$$\cdots\cdots\cdots+\frac{n(n-1)(n-2)\cdots\cdots\cdots 2\,.\,1\,.\,x^{m+n+1}}{(m+1)(m+2)\cdots\cdots\cdots\ m+n+1}.$$

When $x=0$, all the terms of this series vanish, and when $x=1$ they all vanish excepting the last; therefore between the limits $x=0$ and $x=1$, the value of the integral is the last term of the series when x in that term $=1$; that is to say,

$$\int_0^1 x^m(1-x)^n dx=\frac{n(n-1)(n-2)\cdots\cdots\ 2\,.\,1}{(m+1)(m+2)\cdots\cdots m+n+1}.$$

For the sake of brevity, let the symbol $[x]$ be adopted to represent the continued product $1\,.\,2\,.\,3\ldots x$ of the natural numbers from 1 to x,[1] whence by analogy $[x+y]$ will represent the continued product of the same series from 1 to the number denoted by $x+y$. Multiplying, then, the numerator and denominator of the above expression by $1\,.\,2\,.\,3\ldots\ldots m=[m]$, we get

$$\int_0^1 x^m(1-x)^n dx=\frac{[m][n]}{[m+n+1]};$$

whence the probability of the hypothesis, in consequence of the equation above found, becomes

$$\varpi=\frac{[m+n+1]}{[m][n]}x^m(1-x)^n.$$

From this value of ϖ we are enabled to deduce that of Π, the probability of drawing a white ball at the next trial. By (45) $\Pi=\Sigma\varpi p$. Now, since by hypothesis the number of white balls in the urn is to the whole number of both colours in the ratio of x to 1, the probability of drawing a white ball is x; consequently $p=x$, and therefore $\Pi=\Sigma\varpi x=\int_0^1\varpi x dx=\frac{[m+n+1]}{[m][n]}\int_0^1 x^{m+1}(1-x)^n dx$. But the value of $\int_0^1 x^{m+1}(1-x)^n dx$ will evidently be obtained by substituting $m+1$ for m in the expression found for $\int_0^1 x^m(1-x)^n dx$. This substitution gives

$$\int_0^1 x^{m+1}(1-x)^n dx=\frac{[m+1][n]}{[m+n+2]},$$

whence, observing that $[m+1]\div[m]=m+1$, and $[m+n+2]\div[m+n+1]=m+n+2$, we have

$$\Pi=\frac{m+1}{m+n+2}.$$

The probability of the contrary event, or of drawing a black ball, is $1-\Pi=\frac{n+1}{m+n+2}$. As the numbers m and n become larger, these two fractions approach nearer and nearer to their limits $\frac{m}{m+n}$ and $\frac{n}{m+n}$, which are the *a priori* probabilities p and q of the respective events when the ratio of the number of white balls in the urn is to that of the black balls as m to n.

52. The probability of drawing m' white balls and n' black balls in $m'+n'$ future trials is found in a similar manner, and the problem may be thus stated. E and F are two contrary events, depending on constant but unknown causes; and it has been observed, that in $m+n=h$ successive instances the event E has occurred m times and F n times, required the probability that in $m'+n'=h'$ future instances, E will occur m' times and F n' times.

Assume, as in the last case, the facility of the occurrence of E to that of F to be in the ratio of x to $1-x$; we have then, as before, for the probability of the hypothesis, $\varpi=\frac{[h+1]}{[m][n]}x^m(1-x)^n$. Now on this hypothesis the probability of E in the next instance is x, and that of F is $1-x$, whence the probability of m' times E and n' times F in the next h' trials being denoted by p, we have (12) $p=U'x^{m'}(1-x)^{n'}$, making $U'=\frac{1\,.\,2\,.\,3\ldots h'}{1\,.\,2\,.\,3\ldots m'\times 1\,.\,2\,.\,3\ldots n'}=\frac{[h']}{[m'][n']}$. We have therefore $\varpi p=U'\frac{[h+1]}{[m][n]}x^{m+m'}(1-x)^{n+n'}$ for the probability of the compound event on this hypothesis. To find its probability Π on the infinite number of hypotheses formed by supposing x to increase by infinitely small increments from $x=0$ to $x=1$, we have $\Pi=\Sigma\varpi p=\int_0^1\varpi p dx$. On substituting for ϖp the value just found, we get $\Pi=U'\frac{[h+1]}{[m][n]}\int_0^1 x^{m+m'}(1-x)^{n+n'}dx$, and it is manifest that the value of this integral will be obtained by substituting $m+m'$ for m, and $n+n'$ for n in the value of $\int_0^1 x^m(1-x)^n dx$ found above. This substitution gives

$$\int_0^1 x^{m+m'}(1-x)^{n+n'}dx=\frac{[m-m][n+n']}{[h+h'+1]},$$

whence we conclude

$$\Pi=U'\frac{[m+m'][n+n'][h+1]}{[m][n][h+h'+1]}.$$

The most probable hypothesis will be found by making the value of ϖ a maximum, or its differential coefficient equal to zero. Differentiating the equation $\varpi=\frac{[h+1]}{[m][n]}x^m(1-x)^n$, and making $\frac{d\varpi}{dx}=0$, we get $m(1-x)=nx$, whence $x=\frac{m}{m+n}$. The most probable supposition, therefore, respecting the contents of the urn is, that the two sorts of balls are in the same proportions as have been shewn by the previous drawings. We shall have further occasion for these formulæ when we come to consider the cases in which m and n are large numbers.

SECT. VI.—OF BENEFITS DEPENDING ON THE PROBABLE DURATION OF HUMAN LIFE.

53. In applying the principles of the theory of probability to the determination of the values of benefits depending on life, the fundamental element which it is necessary to determine from observation is the probability that an individual at every given age within the observed limits of the duration of life, will live over a given portion of time, for instance one year; for when this has been determined for each year of age, the probability that an individual, or any number of individuals, will live over any assigned number of years, is easily deduced. Thus, if the probabilities that an individual A, whose age is y, will live over 1, 2, $3\ldots x$ years, be denoted respectively by $p_1, p_2, p_3\ldots p_x$; and if $q_1, q_2, q_3\ldots q_x$ denote the same probabilities in respect of an individual whose age is $y+1$ years; $r_1, r_2, r_3\ldots r_x$, the same in respect of an individual whose age is $y+2$ years, and so on; then, since the probability p_2 which A has of living over 2 years is obviously compounded of the probability p_1 of his living over 1 year, and of the probability q_1 that, having attained the age $y+1$, he will live another year, we

---

[1] This convenient notation has been adopted by Mr. De Morgan.

have, by (7), $p_2=p_1 q_1$. Again, the probability p_3 that A will live over three years, being compounded of the probability p_2 that he will live over two years, and of the probability r_1 that, having attained the age $y+2$ years, he will survive another year, we have $p_3=p_2 r_1=p_1 q_1 r_1$. In like manner $p_4=p_1 q_1 r_1 s_1$, and so on; so that the probabilities p_2, p_3, $p_4 \ldots p_x$ are successively derived from p_1, q_1, r_1, s_1, &c. which are supposed to be the data of observation.

If a large number n of individuals, all born in the same year, were selected, and if it were observed that the number of them remaining alive at the end of the first year is n_1, at the end of the second year n_2, at the end of the third n_3, and so on, then the probabilities p_1, p_2, p_3, &c. would be given directly by the observation, being respectively equal to the quotients $\frac{n_1}{n}$, $\frac{n_2}{n}$, $\frac{n_3}{n}$, &c. But the most accurate observations of mortality are furnished by the experience of the annuity and assurance offices, where they are not made on an isolated number, diminishing, and consequently giving a less valuable result every year, but on a comparison of the numbers which, in a series of years, enter upon and survive each year of age. This observation gives p_1, q_1, r_1, s_1, &c, whence p_2, p_3, p_4, &c. are found, as above, for every year of life.[1]

54. The values of annuities on lives, and of reversionary sums to be paid on the failure of lives, are found by combining the probabilities p_1, p_2, p_3, &c. with the rate of interest of money. Let $r=$ the rate of interest, that is to say, the interest of L.1 for a year, and $v=$ the present value of L.1 to be received at the end of a year, we shall then have $v=1\div(1+r)$. Now an annuity, payable yearly, is always understood in this sense, that the first payment becomes due at the end of a year after the annuity is created. Suppose then the annuity to be L.1, the present value of the first payment, if it were to be received certainly, is v; but the receipt of this sum is contingent on the annuitant being alive at the end of the year, the probability of which we suppose to be p_1; therefore (7) the present value of L.1 subject to the contingency, is vp_1. In like manner, the present value of L.1 to be received certainly at the end of x years is v^x; but the annuity will only be received at the end of the xth year if the annuitant be then living, the probability of which is p_x; therefore the present value of that particular payment is $v^x p_x$. Hence if A denote the present value of the annuity, or the sum in hand which is equivalent to all the future payments, we shall have $A=\Sigma v^x p_x$; the sum Σ including all values of x from $x=1$ to $x=$ the number for which $p=0$. If the annuity be a pounds, its value is obviously $=a\Sigma v^x p_x=aA$.

55. The series denoted by $\Sigma v^x p_x$ may be divided into two parts, $\Sigma v^n p_n+\Sigma v^z p_z$, where n is to be taken from 1 to n, and z from $n+1$ to the number for which p vanishes. The first gives the value of the *temporary* annuity on the given life for n years, and the second the value of the *deferred* annuity, that is to say, of the annuity to commence n years hence if the individual shall be then living, and to continue during the remainder of his life. Let A be the value of the annuity on the life of a person now aged y years for the whole of life, $A^{(tn)}$ the value of a temporary annuity on the same life for n years, and $A^{(dn)}$ the value of an annuity deferred n years on the same life, we have then $A=A^{(tn)}+A^{(dn)}$.

To find $A^{(dn)}$, let A_n be the value of an annuity on a life aged $y+n$ years. If the person now aged y years lives over n years, the value of an annuity on the remainder of his life will *then* be A_n. The present value of this sum, if it were to be received certainly, is $v^n A_n$, and the probability of receiving it is p_n; therefore its value is $v^n p_n A_n$. Hence

$$A^{(dn)}=v^n p_n A_n, \text{ and } A^{(tn)}=A-v^n p_n A_n;$$

so that the values of temporary and deferred annuities are readily computed from tables of A and p for all the different ages.

56. The equation $A=A^{(tn)}+A^{(dn)}$ gives a formula by which the values of A are readily deduced from one another. Let $n=1$; we have then $A=A^{(t1)}+vp_1 A_1$. But $A^{(t1)}$, the value of an annuity for one year, is merely the value of the first payment to be received in the event of the given life surviving one year. Its value is therefore vp_1; and we have consequently $A=vp_1+vp_1 A_1$, or $A=vp_1(1+A_1)$. This formula, which gives the value of an annuity at any age in terms of the next higher age, and greatly facilitates the computation of the annuity tables, is due to Euler.

57. The value of an annuity on the joint lives of any number of individuals, that is, to continue only while they are *all* living, is calculated precisely in the same manner as the annuity on a single life. Let there be any number of individuals, A, B, C, D, &c. and let the probabilities of each living over one year be respectively p_1, q_1, r_1, s_1, &c. and let P_1 be the probability that they will *all* live over one year; then

$$P_1=p_1\times q_1\times r_1\times s_1, \text{ \&c.}$$
$$P_2=p_2\times q_2\times r_2\times s_2, \text{ \&c.}$$
$$\cdots\cdots\cdots\cdots\cdots\cdots$$
$$P_x=p_x\times q_x\times r_x\times s_x, \text{ \&c.}$$

and the value of an annuity of L.1 on the joint lives is $\Sigma v^x P_x$, from $x=1$ to $x=$ the number which renders any one of the probabilities p, q, r, s, &c. nothing.

58. The value of an annuity on the survivor of any number of given lives, that is, to continue so long as any one of them exists, is thus found. The probability that A will be alive at the end of the xth year being p_x, the probability that he will not be alive at the end of that time is $1-p_x$. The probability that *all* the lives will be extinct at the end of the xth year is therefore

$$(1-p_x)(1-q_x)(1-r_x)(1-s_x), \text{ \&c.}$$

and the probability that they will not all be extinct, or that at least one of them will be in being, is

$$1-(1-p_x)(1-q_x)(1-r_x)(1-s_x), \text{ \&c.}$$

which becomes by multiplication

$$\begin{aligned}&p_x+q_x+r_x+s_x+\text{\&c.}\\&-p_x q_x-p_x r_x\ldots\ldots-q_x r_x-q_x s_x\ldots\ldots-r_x s_x-\text{\&c.}\\&+p_x q_x r_x+p_x q_x s_x\ldots\ldots+q_x r_x s_x+\text{\&c.}\\&-p_x q_x r_x s_x-\text{\&c.}\\&+\text{\&c.}\end{aligned}$$

Multiplying each of the terms by v^x, and taking the sums of the respective products from $x=1$, and observing that $\Sigma v^x p_x q_x$ is the value of the annuity on the joint lives of A and B, $\Sigma v^x p_x q_x r_x$ that on the joint lives of A, B, and C, and so on, we have this rule:—

The value of an annuity on the survivor of any number of lives is equal to the sum of the annuities on each of the lives, minus the sum of the annuities on each pair of joint lives, plus the sum of the annuities on the joint lives taken by threes, and so on. When there are only two lives, the value of the annuity on the life of the survivor becomes

$$\Sigma v^x p_x+\Sigma v^x q_x-\Sigma v^x p_x q_x.$$

59. Let V denote the value of an assurance on the life of A, or the present worth of L.1 to be received at the end of the year in which A shall die. In respect of any year, the xth, after the present, the probability of A dying in the course of that year is $p_{x-1}-p_x$. For let u be the probability that a life $x-1$ years older than A will live over one year, then $1-u$ is the probability of a life of that age not living over one year; therefore p_{x-1} being the probability of A living over $x-1$ years, $p_{x-1}(1-u)$ is the chance of his living over $x-1$ years, and dying in the following year (7). But $p_{x-1}(1-u)=p_{x-1}-p_{x-1}u$; and by (53), $p_{x-1}u=p_x$; therefore $p_{x-1}-p_x$ is the chance that A will survive $x-1$

---

[1] For further details on this subject, see MORTALITY, vol. xv. p. 637.

years and not survive x years. Now v^x is the value of L.1 to be received certainly at the end of the xth year; therefore in respect of the xth year the value of the expectation is $v_x(p_{x-1}-p_x)$; whence we have for the value of the assurance

$$V=\Sigma v^x(p_{x-1}-p_x),$$

from $x=1$ to $x=$ the number which makes $p=0$. Now, if we observe that $p_0=1$, and $\Sigma v^x p_{x-1}=v\Sigma v^{x-1}p_{x-1}$, it will be obvious that $\Sigma v^x p_{x-1}=v(1+\Sigma v^x p_x)$; whence, denoting $\Sigma v^x p_x$ by A, (A being as in (54) the value of the annuity on the given life), we have

$$V=v(1+A)-A;\ \text{or}\ V=v-(1-v)A.$$

60. The values of assurances on joint lives, (that is, to be paid at the end of the year in which any one of the lives shall fail), or on the survivor of any number of joint lives, are calculated from the corresponding annuities by means of the same formula. Thus, let A′ be the value of an annuity of L.1 on any number of joint lives, and V′ the value of an assurance of L.1 on the same joint lives, then $V'=v-(1-v)A'$. If A″ be the annuity, and V″ the assurance on the life of the survivor of any number of given lives, we have still $V''=v-(1-v)A''$.

61. Assurances on lives are usually paid not in single payments, but by equal yearly payments, the first being made at the time the contract is entered into, and the succeeding ones at the end of each future year during the life of the assured. The present value of the sum which the assured contracts to pay is therefore equal to the first payment added to the value of an annuity of the same amount on his life; and if the assurance is made on terms of mathematical equality, this sum must be precisely equal to the value of the assurance in a single payment. Therefore, if y denote the amount of the yearly payment, we have the equation $y(1+A)=V$; whence $y=V\div(1+A)$.

62. The value of a temporary assurance for n years, that is, of an assurance to be paid only in the event of the individual dying before the end of n years is thus found. Let V be the present value of L.1, to be paid on the death of a person now aged y years, and V_n the present value of L.1, to be paid on the death of a person now aged $y+n$ years. At the end of n years from the present time, the value of L.1 assured on the life of a person now aged y years will be V_n, if he be then living. But the present value of L.1 to be received certainly at the end of n years is v^n; and the probability that the life will continue n years is p_n; therefore the present value of V_n, subject to the contingency of the life continuing n years, is $v^n p_n V_n$. If, therefore, we subtract this from V, we shall have the value of the temporary assurance in a single payment, namely $V-v^n p_n V_n$.

The equivalent annual premium is found by observing, that as the first payment is made immediately, and n payments are to be made in all, the value of all the premiums after the first is that of a temporary annuity of the same amount for $n-1$ years. Denoting therefore the annual premium by u, and the value of a temporary annuity for $n-1$ years by $A^{(tn')}$, the value of all the premiums is $u+uA^{(tn')}=u(1+)A^{(tn')}$; and we have consequently $u(1+A^{(tn')})=V-v^n p_n V_n$, whence

$$u=\frac{V-v^n p_n V_n}{1+A^{(tn')}}.$$

63. The following question is of frequent occurrence. Required the present value of a sum of money to be received at the end of the year in which A dies, provided he die while B is living.

Let the sum be L.1, W= its present value, $p_x=$ the probability of A living over x years, and $q_x=$ the probability of B living over x years. The chance of receiving the sum at the end of any given year, the xth, depends on two contingencies; 1. A may die in the course of that year, and B live over it; 2. A and B may both die in that year, A dying first. The probability of A dying in the xth year has been shewn (59) to be $p_{x-1}-p_x$; whence (7) the probability of the first contingency is $(p_{x-1}-p_x)q_x$. The probability that A and B will both die in the xth year is $(p_{x-1}-p_x)(q_{x-1}-q_x)$; and for so short a period as one year, it may be considered an even chance whether A or B will die first, whatever be the difference of their ages; therefore the probability in respect of the second contingency is $\frac{1}{2}(p_{x-1}-p_x)(q_{x-1}-q_x)$. Hence the whole probability of the sum being received at the end of the xth year, is $(p_{x-1}-p_x)q_x+\frac{1}{2}(p_{x-1}-p_x)(q_{x-1}-q_x)=\frac{1}{2}(p_{x-1}-p_x)(q_{x+1}+q_x)$, which being developed, and multiplied by v^x, becomes

$$\tfrac{1}{2}v^x(p_{x-1}q_{x-1}+p_{x-1}q_x-p_x q_{x-1}-p_x q_x),$$

and the sum of all the values of this expression from $x=1$, gives the value of W.

It has been already shewn (59) that $\Sigma v^x(p_{x-1}-p_x)=v-(1-v)A$, where A= the annuity on the life of A. In like manner, if we denote by $\overline{AB}$ the value of an annuity on the joint lives of A and B, we shall have $\Sigma v^x(p_{x-1}q_{x-1}-p^x q^x)=v-(1-v)\overline{AB}$, which is the value of an assurance to be paid on the death of the first dying. Assume p' such that $p'_x=p'_1 p_{x-1}$, then p'_x is evidently the probability that an individual A′ one year *younger* than A, will live over x year (53), and $\Sigma v^x p_{x-1}q_x=\frac{1}{p'_1}\Sigma v^x p'_x q_x=\frac{1}{p'_1}\overline{A'B}$; denoting by $\overline{A'B}$ the value of an annuity on the joint lives of A′ and B. Again, let $q'_x=q'_1 q_{x-1}$, then q'_x is the probability that B′, who is one year *younger* than B, will live over x years, and $\Sigma v^x p^x q_{x-1}=\frac{1}{q'_1}\Sigma v^x p_x q'_x=\overline{AB'}$; denoting by $\overline{AB'}$ the value of an annuity on the joint lives of A and B′. Collecting the different terms, we have therefore

$$W=\tfrac{1}{2}\left\{v-(1-v)\overline{AB}+\frac{1}{p'_1}\overline{A'B}-\frac{1}{q'_1}\overline{AB'}\right\},\ \text{whence W}$$

is easily computed from tables of annuities on joint lives.

If A and B are both of the same age, the two last terms destroy each other, and W is equal to $\frac{1}{2}$ the value of L.1, to be paid on the failure of the joint lives, as it evidently ought to be, since there is in this case the same chance of A dying before B as of B dying before A.

The formula gives the value of L.1 in a single payment; the equivalent yearly payment is W divided by $1+\overline{AB}$, for the contract ceases on the failure of the joint lives by the death of either.

It would be easy to extend the formula to the case of an assurance to be paid on the contingency of the failure of any number of lives during the continuance of any number of other lives, or of an assurance to continue only during a stated time; but as it is not our purpose to give solutions of the various problems of this kind which may occur in practice, but merely to shew the manner in which the general principles of the theory are applied to them, we shall not pursue the subject farther, but refer the reader to the article ANNUITIES, and to the standard works of Baily[1] and Milne,[2] in which it is treated in detail.

SECT. VII. OF THE APPLICATION OF THE THEORY OF PROBABILITY TO TESTIMONY, AND TO THE DECISIONS OF JURIES AND TRIBUNALS.

64. The case of a witness making an assertion may be represented by an urn containing balls of two colours, the

---

[1] *The Doctrine of Life Annuities and Assurances analytically investigated and practically explained, &c.* By Francis Baily. London, 1813.

[2] *A Treatise on the Valuation of Annuities and Assurances on Lives and Survivorships, &c.* By Joshua Milne. London, 1815.

ratio of the number of one colour to that of the other being unknown, but presumed from the result of a number of experiments, which consist in drawing a ball at random, and replacing it in the urn after each trial. A true assertion being represented by a ball of one colour, and a false one by a ball of the other, it follows from the theorem in (51), that if a witness has made $m+n$ assertions, of which m are true and n false, the probability of a future assertion being true is $\frac{m+1}{m+n+2}$, and that of its being false $\frac{n+1}{m+n+2}$. Let the first of these fractions be represented by v, and the second by w, then v is the measure of the veracity of the individual, or the probability of his speaking the truth, and w the opposite probability, since $v+w=1$. In general, the existing data are insufficient to enable us to determine the numerical values of v and w in this manner; and therefore in applying the formulæ to particular cases, we must assign arbitrary values to these quantities, founded on previous knowledge of the moral character of the individual, or on some notions, more or less sanctioned by experience, of the relative number of true and false statements made by men in general, placed in similar circumstances.

65. Having assumed v and w, let us suppose a witness to testify that an event has taken place, the *a priori* probability of which is p, and let it be proposed to determine the probability of the event after the testimony. In this case the event observed (E) is the assertion of the witness, and two hypotheses only can be made respecting its cause; 1st, that the event testified really took place; and 2d, that it did not. On the first hypothesis the witness has spoken the truth, the probability of which is v; and an event has occurred of which the probability is p; therefore (7) the probability (P_1) of the coincidence is vp. On the second hypothesis, the witness has testified falsely, the probability of which is w; and the event attested did not happen, the probability of which is q; therefore the probability (P_2) of the coincidence is wq. Hence, by the formula (47) $\varpi_1=P_i\div\Sigma P_i$) the probability ($\varpi_1$, of the first hypothesis becomes $\frac{vp}{vp+wq}$, and the probability (ϖ_2) of the second $\frac{wq}{vp+wq}$. The sum of these two probabilities is unit, a condition which ought evidently to be fulfilled, since no other hypothesis can be made, and consequently one or other of the two must be true. It is to be observed, that these values of ϖ_1 and ϖ_2 are the respective probabilities, after the testimony has been given, that the event attested took place, and that it did not.

Since $\varpi_1=\frac{vp}{vp+wq}$, we have $\varpi_1-p=\frac{p(v-vp-wq)}{vp+wq}$ $=\frac{p\{v(1-p)-wq\}}{vp-wq}=\frac{p(vq-wq)}{vp-wq}$; but $v-w=v-1+v=2v-1$, therefore $\varpi_1-p=\frac{p(2v-1)q}{vp+wq}$. This fraction being positive or negative, according as $2v-1$ is greater or less than unity, or as v is greater or less than $\frac{1}{2}$, it follows that if $v>\frac{1}{2}$, then $\varpi_1>p$; that is to say, the probability of the event after the testimony is greater than its *a priori* probability when the veracity of the witness is greater than $\frac{1}{2}$. On the contrary, if the veracity of the witness is less than $\frac{1}{2}$, the effect of the testimony is to render the probability of the event less than its *a priori* probability.

66. If the event asserted by the witness be of such a nature that its occurrence is *a priori* extremely improbable, so that p is a very small fraction, and q consequently approaches nearly to unity, although at the same time the veracity of the witness be great, and measured by a fraction approaching to unity, the value of ϖ_1 becomes nearly equal to $p\div w$, (for on this supposition $p+wq\cdot v$ is nearly equal to w). But it is obvious, that however great the improbability of a witness giving false testimony may be supposed, the improbability of a physical event may be any number of times greater; in other words, however small a value may be given to w, the value of p may still be any number of times smaller; so that notwithstanding the veracity of the witness, the probability of the event after the testimony, namely $\varpi_1=p\div w$ may be less than any assignable quantity. On this principle mankind do not easily give credence to a witness asserting a very extraordinary or improbable event. The odds against the occurrence of the event may be so great, that the testimony of no single witness, however respectable his character, would suffice to induce belief.

67. In the case of the character of a witness being altogether unknown, we may suppose v to have all possible values within certain limits, and to find the value of ϖ_1 by integrating the fraction $\int\varpi_1 dv$ between those limits. Since $\varpi_1=\frac{vp}{vp+wq}$, we have $\int\varpi_1 dv=\int\frac{pvdv}{vp+wq}$, which on substituting $1-v$ and $1-p$ for w and q respectively, becomes $\int\frac{pvdv}{1-p+(2p-1)v}$, the integral of which is

$$p\left\{\frac{v}{2p-1}-\frac{1-p}{(2p-1)^2}\log.\left(1-p+(2p-1)v\right)\right\}+\mathrm{C},$$

C being a constant, the value of which will be determined from the assumed limits. If v be supposed to vary between the limits $v=0$ and $v=1$, then

$$\int\varpi_1 dv=\frac{p}{2p-1}\left\{1-\frac{1-p}{2p-1}\log.\frac{p}{1-p}\right\};$$

and if we assume $p=\frac{3}{4}$, we have $\int\varpi_1 dx=\frac{3}{2}(1-\frac{1}{2}\log.3)$, which, since the logarithm is the Napierian logarithm, and Nap. log. $3=1.0986$, becomes $\frac{3}{2}\times.4507=.676$, or nearly $\frac{2}{3}$. Whence we see, that on this hypothesis the probability of the event is diminished in consequence of the testimony.

68. The credit due to the testimony of a witness depends not merely on his good faith, but also on the probability that he is not himself deceived with respect to the event he asserts. The chances of a witness being deceived through credulity or ignorance are much more numerous in general than the chances of intentional fraud; and this must be the case more particularly when the event is of such a nature that it may happen in various ways which may be mistaken one for another: as for instance, in the case of a lottery ticket being drawn, and the witness asserting that it bears a particular number, which might with equal probability be any other number on the wheel. The following question will illustrate the method of applying the calculus when a distinction is made between these sources of error.

An urn contains s balls, of which a_1 are marked A_1, a_2 marked A_2......a_n marked A_n. A ball having been drawn at random, a witness of the drawing affirms that the ball drawn is marked A_m; required the probability of the testimony being true.

Here we have $s=a_1+a_2+a_3......+a_n$, (n being the number of the different indices or sorts of balls); so that if we make $p_1=a_1\div s$, $p_2=a_2\div s$.....$p_m=a_n\div s$, then p_1 is the *a priori* probability that the ball drawn is of the class marked A_1, p_2 the probability that it belongs to the class whose index is A_2, and so on. It is evident that n different hypotheses may be made respecting the index of the ball which has been drawn, for it may belong to any one of the different classes A_1, A_2...A_n. Let the probabilities of these hypotheses be respectively ϖ_1, ϖ_2...ϖ_n, (that is, in respect of any particular index i, ϖ_i is the probability after the assertion that the ball drawn is marked A_i); and let the probabilities of the assertion on each of these hypotheses be respectively P_1, P_2...P_n, (that is, if the ball drawn be marked A_i, then P_i is the probability the witness will assert it to be marked A_m). Lastly, let v be the veracity of the witness, and u the probability that he has not been deceived.

(1.) Let us first consider the hypothesis that the ball drawn is marked A_m, and consequently that the assertion is true. In order to find P_m, the probability of the assertion being made, there are four cases to be considered. 1st, we may suppose the witness is not deceived himself (u), and that he speaks the truth (v). The probability of the assertion in this case is uv. 2d, The witness knows the truth, but intends to deceive, or testifies falsely. In this case the probability of the assertion being made, on the hypothesis under consideration, is 0. 3d, The witness has been deceived himself, but intends to speak the truth. In this case also the probability of the assertion being made is 0. 4th, The witness has been deceived himself, and intends to deceive. In this case the assertion might be made; and to find the probability of its being made we have to consider, that since the witness has been deceived, he must have supposed some other index than A_m to have been drawn; and since he intends to deceive, he must assert some other index to be drawn than that which he supposes to be drawn. Setting aside, therefore, the index which he supposes to have been drawn, there remain $n-1$ others, any one of which he is as likely to name as any other. The probability, therefore, of his naming A_m when he intends to deceive is $1\div(n-1)$. Hence the probability of the assertion in this case is compounded of the probabilities of three simple events, as follows: 1. Probability the witness is deceived $=(1-u)$; 2. Probability he intends to deceive $=(1-v)$; 3. Probability he names A_m $=1\div(n-1)$. The probability of the assertion is therefore in this case $=(1-u)(1-v)\div(n-1)$. Adding this to the probability found in the first case, we have P_m, the whole probability of the assertion being made on the hypothesis that the index of the ball drawn was A_m, namely

$$P_m=uv+\frac{(1-u)(1-v)}{n-1}.$$

(2.) Let us now consider one of the remaining hypotheses, and suppose that the ball actually drawn was marked A_i, and not A_m, as attested by the witness. As before, there are four possible cases for consideration. 1st, The witness knows the fact and speaks the truth. In this case the assertion could not be made, or its probability is 0. 2d, The witness knows the fact, and intends to deceive. In this case the probability of his asserting A_m to be drawn is compounded of the probability that he is not deceived (u), the probability that he testifies falsely ($1-v$), and the probability that, knowing the index A_i to be drawn, he selects A_m from among the $n-1$ which remain after rejecting A_i, ($1\div(n-1)$). The probability of the assertion being made in this case is therefore $u\,(1-v)\div(n-1)$. 3d, The witness is deceived, and intends to speak the truth. By reasoning as in the last case, it is easy to see that the probability of the assertion being made in this case is $v\,(1-u)\div(n-1)$. 4th, The witness is deceived, and intends to deceive. The probability of the assertion being made in this case will be found by considering, that as the witness is himself deceived, he must suppose some particular index to be drawn different from A_i, (which is drawn by hypothesis), for instance A_e, the probability of which is $1\div(n-1)$; and intending to deceive, he must fix on some index different from A_e, which he supposes to be drawn; and he announces A_m, the probability of which selection is also $1\div(n-1)$. The probability, therefore, that the witness supposes A_e to be drawn, and annnounces A_m, is $1\div(n-1)^2$. But it is evident, that whatever can be affirmed with respect to the particular index A_e, may be affirmed with equal truth of every one of the other n indexes, excepting A_i, which is actually drawn, (since by hypothesis the witness is deceived), and A_m, which he announces, (since by hypothesis he lies). There are therefore $n-2$ different ways in which he may at the same time be deceived, and intend to deceive, and announce A_m; consequently the probability of this announcement in any of these ways is $(n-2)\div(n-1)^2$. Multiplying this into the probability of his being deceived ($1-u$), and the probability of his giving false testimony ($1-v$), the probability of the assertion in this case becomes $\dfrac{(1-u)(1-v)(n-2)}{(n-1)^2}$. Hence the whole probability of the assertion, in all the cases included in the hypothesis that the ball actually drawn was marked A_i, is

$$P_i=\frac{u(1-v)}{n-1}+\frac{(1-u)v}{n-1}+\frac{(1-u)(1-v)(n-2)}{(n-1)^2}.$$

As this expression will evidently be the probability of the assertion on any other of the $n-1$ hypotheses that the ball actually drawn was marked with an index different from A_m, the sum of the probabilities of the assertion on all these hypotheses is ΣP_i, where i is successively each of the numbers 1, 2, 3,...n, excepting m.

We have now to find ϖ_m, the probability of the first hypothesis. Since the hypotheses, in the present question, are not all equally probable *a priori*, we must have recourse to the formula (49) $\varpi_i=\lambda_i P_i\div\Sigma\lambda_i P_i$, and consequently in the present case we have

$$\varpi_m=\frac{\lambda_m P_m}{\lambda_m P_m+\Sigma\lambda_i P},$$

the sign of summation Σ including every value of i from 0 to n, excepting $i=m$. Now the value of P_i being the same in respect of each of the hypotheses which suppose the assertion untrue, $\Sigma\lambda_i P_i=P_i\Sigma\lambda_i$; and the sum of all the values of λ_i from $i=0$ to $i=n$ being 1, on excluding $\lambda_m=a_m\div s$, we have $\Sigma\lambda_i=(s-a_m)\div s$. Substituting this, together with the values of P_m and P_i, as above found, and making $u'=1-u$, $v'=1-v$, the formula becomes, after the proper reduction,

$$\varpi_m=\frac{a_m\{(n-1)uv+u'v'\}}{a_m\{(n-1)uv+u'v'\}+(s-a_m)\{u'v+uv'+\frac{n-2}{n-1}u'v'\}};$$

which is the probability of the hypothesis that a ball marked A_m was drawn, or that the testimony is true.

When there are no two balls in the urn having the same index, the numbers a_1, a_2, a_3, &c. become each $=1$, and $s=n$. In this case the formula gives

$$\varpi_m=\frac{(n-1)uv+u'v'}{(n-1)uv+u'v'+(n-1)(u'v+uv')+(n-2)u'v'},$$

which, on observing that $uv+u'v+uv'+u'v'=1$, becomes by reduction

$$\varpi_m=uv+\frac{(1-u)(1-v)}{n-1}.$$

This is the probability of the truth of the testimony of a witness, who affirms that the number m is drawn from an urn which contains n balls, numbered 1, 2, 3...n. It is obvious, that when u and v are fractions approaching to unity, and n is a considerable number, the second term becomes very small, and may be neglected. The probability then becomes simply $\varpi_m=uv$.

69. We now proceed to consider the probability of an event attested by several witnesses; and first let us suppose the witnesses to agree in their testimony. The measures of the veracity of the several witnesses being respectively v_1, v_2, v_3, &c., and the *a priori* probability of the event being p, we have by (58) for its probability after the testimony of the first witness,

$$\varpi_1=\frac{v_1 p}{v_1 p+(1-v_1)(1-p)}.$$

In order to find the probability of the event after the second witness gives his testimony, we may suppose the *a priori* probability to be changed from p to ϖ_1 by the testimony of the first witness, and the same formula gives

$$\varpi_2=\frac{v_2\varpi_1}{v_2\varpi_1+(1-v_2)(1-\varpi_1)}=\frac{v_1v_2p}{v_1v_2p+(1-v_1)(1-v_2)(1-p)}.$$

Let a third witness now come forward, and give testimony in favour of the same event. Its probability after his testimony will become in like manner

$$\varpi_3=\frac{v_3\varpi_2}{v_3\varpi_2+(1-v_3)(1-\varpi_2)}=\frac{v_1v_2v_3p}{v_1v_2v_3p+(1-v_1)(1-v_2)(1-v_3)(1-p)}.$$

In general, let ϖ^x be the probability of an event after it has been attested by x witnesses, and let v_x be the veracity of the last witness, then ϖ_{x-1} being the probability of the event after $x-1$ eyewitnesses have each testified in its favour, we have

$$\varpi_x=\frac{v_1v_,\ldots\ldots v_xp}{v_1v_2\ldots v_xp+(1-v_1)(1-v_2)\ldots(1-v_x)(1-p)}.$$

If we suppose the witnesses all equally credible, or that $v_1=v_2=v_3\ldots=v_x$, this becomes

$$\varpi_x=\frac{v_xp}{v^xp+(1-v)^x(1-p)}=\frac{1}{1+\left(\frac{1-v}{v}\right)^x\frac{1-p}{p}}.$$

Now, if $v=\frac{1}{2}$, then $(1-v)\div v=1$, and $\varpi_x=p$; whence it appears that the probability of an event is not increased by the testimony of any number of witnesses, when the veracity of each is only $\frac{1}{2}$; but when v is greater than $\frac{1}{2}$, the event becomes more probable as the number of witnesses is greater, and when v is a considerable fraction, its probability increases very rapidly with the number of witnesses.

70. When the values of v and p are given, that of x in the last formula may be found so as to render ϖ_x of any given value. Hence we may find the number of witnesses required to make it an even wager, whether an event exceedingly improbable, and in favour of which they give unanimous testimony, has happened or not. For example, let the odds against the event be a million million to one, that is, let $p=\frac{1}{1{,}000{,}000{,}000{,}001}=\frac{1}{10^{12}+1}$, and let v the veracity of each witness be $\frac{9}{10}$. In order that ϖx may equal $\frac{1}{2}$, we must have $\left(\frac{1-v}{v}\right)^x\frac{1-p}{p}=1$. Now $\frac{1-v}{v}=\frac{1}{9}$, and $\frac{1-p}{p}=10^{12}$, therefore $\left(\frac{1}{9}\right)^x\times10^{12}=1$; whence $x\log\frac{1}{9}=\log\frac{1}{10^{12}}$ or $x\log 9=12$ and therefore $x=\frac{12}{\cdot95424}=12\cdot6$ nearly, so that 13 independent witnesses would suffice to render it more probable that the event really took place than that it did not.

This example is given by Mr. Babbage, (Ninth Bridgewater Treatise, Note E), with a view to shew the fallacy of Hume's celebrated argument respecting miracles. What the example proves is simply this, that if we suppose an urn to contain a million million of white balls, and only one black ball, and that on a ball being drawn at random from the urn, thirteen eyewitnesses of the drawing, each of whom makes only one false statement in ten, without collusion, and independently of each other, affirm to A, who was not present at the drawing, that the ball drawn was black, then A would have rather a stronger reason for believing than for disbelieving the testimony. But it is sufficiently obvious, that the event attested in this case, though exceedingly improbable *a priori*, cannot be regarded as in any way miraculous. On the contrary, the black ball might be drawn with the same facility, and was *a priori* as likely to be drawn, as any other *specified* ball in the urn. Let it be granted that an event is within the range of fortuitous occurrence, and that there exists a single chance in its favour out of any number of millions of chances, it may then happen in any one trial; nay, a number of trials may be assigned, such that its non-occurrence would be many times more improbable than the contrary.

71. Let us next consider the case of a number of witnesses contradicting each other. If the first witness announces an event of which the probability is p, then the probability, after the testimony, of its having happened is ϖ_1, and the probability that it has not happened $1-\varpi_1$. Suppose a second witness now to appear, and testify that the event has not happened, and let the probability of the truth of his testimony be denoted by ϖ'_2; then $1-\varpi_1$ being the probability before his testimony was given that what he asserts is true, and v_2 being the measure of his veracity, we have, as in (69), $\varpi'_2=\frac{v_2(1-\varpi_1)}{v_2(1-\varpi_1)+(1-v_2)\varpi_1}$, whence, since

$$\varpi_1=\frac{v_1p}{v_1p+(1-v)(1-p)},$$ there results

$$\varpi'_2=\frac{(1-v_1)v_2(1-p)}{(1-v_1)v_2(1-p)+v_1(1-v_2)p}$$

for the measure of the probability that the event has not happened. The probability that it has happened is therefore $1-\varpi'_2$, and accordingly if ϖ'_2 be less than $\frac{1}{2}$, there is a stronger reason for believing that the event happened than that it did not. The method of forming the expression for the probability of the event, after it has been attested or denied by a third witness, or any number of successive witnesses, is obvious.

If we suppose the values of v_1 and v_2 to be equal, the expression becomes $\varpi'_2=1-p$, which is the *a priori* probability that the event did not happen. It is obvious that this must be the case, inasmuch as two contradictory testimonies of equal weight neutralize each other. In general, the probability of an event which is affirmed by m witnesses, and denied by n witnesses, all equally credible, is the same as that of an event which is affirmed by $m-n$ witnesses who agree in their testimony.

72. When a relation has been transmitted through a series of narrators, of whom the first only has a direct knowledge of the event, and each of the others derives his knowledge from the relation of the preceding, the probability of the event is diminished by every succeeding relation In order to obtain a general expression for the probability of traditionary testimony, we may take the event considered in (68), namely the extraction of a ball marked A_m from an urn containing s balls, of which a_1 are marked A_1, a_2 marked $A_2,\ldots a_n$ marked A_n, there being in all n different indices. Now suppose the relation to have passed through a chain of narrators, T, T_1, $T_2,\ldots T_x$, in number $x+1$, of whom the first only was an eyewitness of the event, each of the others receiving his knowledge of it from the one preceding him, and communicating it in his turn to the succeeding, the question is to determine the probability that a ball marked A_m was drawn, after this event has been narrated by T_x, the last witness of the series.

73. In order to apply the general formula of (68) to this case, it is necessary to remark that the event observed is the attestation of T_x of his having been informed by T_{x-1} that the ball drawn from the urn, the drawing of which was seen by T, was marked A_m. There are n different hypotheses respecting the index of the ball actually drawn, but it is only necessary to consider two of them, namely, the hypothesis that the ball actually drawn was marked A_m, and any one of the other hypotheses which consist in supposing that a ball with a different index from A_m was drawn, for example A_r. Let the probability of the attestation, on the hy-

pothesis that the index of the ball drawn was A_m, be denoted by y_x, and its probability on the hypothesis that the index was A_i by y'_x, (y_x and y'_x corresponding to P_m and P_i in (68), which express the same probabilities in respect of the eyewitness T), then by (68), the probability of the hypothesis that A_m was drawn is

$$\varpi_m=\frac{\lambda_m y_x}{\lambda_m y_x+\Sigma\lambda_i y'_x}.$$

But since y'_x is the same for all the hypotheses that the index drawn was different from A_m, $\Sigma\lambda_i y'_x=y'_x\Sigma\lambda_i$; and by (68) $\Sigma\lambda_i=(s-a_m)\div s$, and $\lambda_m=a_m\div s$, therefore

$$\varpi_m=\frac{a_m y_x}{a_m y_x+(s-a_m)y'_x}.$$

We have now to find y_x and y'_x in terms of x. Let v, v_1, v_2, &c. be the respective probabilities of T, T_1, T_2, &c. speaking the truth, then the probability of T_x speaking the truth is v_x, and the probability that he does not $1-v_x$, whether because he is dishonest, and intends to deceive, or because he has mistaken the statement of the preceding witness. Now there are two ways in which it may happen that A_m is announced by T_x. First, if he speaks the truth, and has been informed by the preceding narrator T_{x-1} that A_m was the index drawn; secondly, if he lies, and has been informed by T_{x-1} that a different index from A_m was drawn. Assuming y_{x-1} to have the same signification with respect to T_{x-1} that y_x has been assumed to have with respect to T_x, (that is to say, the probability of the assertion being made by T_{x-1} on the hypothesis that the ball actually drawn was A_m), the probability of the first of these combinations is $v_x y_{x-1}$. With respect to the second case, it is to be observed, that if T_x announces a different index from that which has been announced to him by T_{x-1}, the chance of his announcing A_m out of $n-1$ indexes different from that announced by T_{x-1} is $1\div(n-1)$; and on multiplying this by the probability $1-v_x$ that the testimony of T_x is false, and by the probability $1-y_{x-1}$ that T_{x-1} has announced a different index from A_m, we have, for the probability of the second combination $(1-v_x)(1-y_{x-1})\div(n-1)$. The whole probability of T_x testifying that A_m was drawn, is therefore, on the first hypothesis, given by the equation,

$$y_x=v_x y_{x-1}+(1-v_x)(1-y_{x-1})\div(n-1).$$

This is an equation of finite differences of the first order, the complete integral of which is

$$y_x=\frac{1}{n}+\frac{C(nv_1-1)(nv_2-1)\ldots(nv_{x-1}-1)(nv_x-1)}{(n-1)^x}.$$[1]

In order to determine the arbitrary constant C, it is to be observed, that, since y_1, $y_2\ldots y_x$, as well as v_1, $v_2\ldots v_x$ apply to the narrators T_1, $T_2\ldots T_x$ respectively, if we suppose $x=o$ the resulting value of the integral will be the probability that A_m was announced by the eyewitness T, on the hypothesis that A_m was actually drawn. Let this probability be P_m; then the equation becomes $P_m=C+1\div n$ whence $C=(nP_m-1)\div n$. If, therefore, we make

$$X=\frac{(nv_1-1)(nv_2-1)\ldots(nv_{x-1}-1)(nv_x-1)}{(n-1)^x}$$

we obtain, on the first hypothesis, for any value of x,

$$y_x=\{1+(nP_m-1)X\}\div n.$$

In the same manner we find the probability y'_x of the testimony given by T_x, on the hypothesis that the ball actually drawn was A_i. The probability of the event, after being testified by the eyewitness, being on this hypothesis P_i, we have,

$$y'_x=\{1+(nP_i-1)X\}\div n.$$

Substituting these values of y_x and y'_x in the expression above found for ϖ_m, we obtain for the probability of the event observed by T, and narrated by T_x, the narration having passed from one to another in the manner supposed,

$$\varpi_m=\frac{a_m\{1+n(P_m-1)X\}}{a_m\{1+(nP_m-1)X\}+(s-a_m)\{1+(nP_i-1)X\}}.$$

74. Since $\dfrac{nv_x-1}{n-1}=v_x-\dfrac{1-v_x}{n-1}$, and since v_x is always less than unity, and n always greater than unity, each of the terms of the series represented by X, whether positive or negative, is a proper fraction, whence the value of X becomes smaller and smaller as x increases. Suppose x infinite, then $X=0$, and $\varpi_m=a_m\div s$, which is the *a priori* probability of the event. Hence we see that the probability of an event transmitted through a series of traditionary evidence becomes weaker at every step, and ultimately equal to the simple probability of the event, independent of any testimony.

75. When the urn is supposed to contain only n balls, each having a different index, the expression for ϖ_m is greatly simplified; for, in this case, $a_m=1, s=n$; therefore, (since $P_m+(n-1)P_i=1$) the denominator becomes n, and we have consequently $\varpi_m=\{1+(nP_m-1)X\}\div n$, which coincides with the value of y_x found above, that is to say, with the probability of the event being testified by T_x on the hypothesis that it actually happened. Laplace, in solving this particular case of the problem, (p. 456) assumes that the probabilities here denoted by y_x and ϖ_m are identical. They are, however, as is evident from the above analysis, quite distinct in their nature, and their values are only equal in the particular case in which $s-a_m$ is to a_m in the ratio of $m-1$ to 1. (Poisson, p. 112.)

76. The question of determining the probability that the verdict of a jury is correct, is precisely analogous to that of finding the probability of an event attested by one or more witnesses. Let us first take the case of a single juror, and assume $u=$ the probability that the juror gives a correct verdict, (that is, correct in respect of the facts), and $p=$ the probability that the accused is guilty before being put on his trial. Suppose the verdict guilty to be returned; two hypotheses may be made respecting the cause of the verdict, first, that the accused is guilty; secondly, that he is innocent. On the first hypothesis, the accused will be condemned if the juror gives a right verdict, the probability of which is u. On the second hypothesis, the accused will be condemned if the juror gives a wrong verdict, the probability of which is $1-u$. But the *a priori* probabilities of these causes (the guilt or innocence of the accused) being respectively p and $1-p$, we have by (49)

$$\varpi_1=\frac{up}{up+(1-u)(1-p)},\qquad \varpi_2=\frac{(1-u)(1-p)}{up+(1-u)(1-p)},$$

ϖ_1 being the probability of the first hypothesis, or the probability that the accused is guilty after the verdict has been given, and ϖ_2 the probability resulting from the verdict that the accused is innocent.

77. Suppose the verdict not guilty to be given, and let ϖ'_1 and ϖ'_2 be the probabilities after the verdict of the two hypotheses. On the first hypothesis, namely, that the accused is guilty, this verdict will be given if the juror gives a wrong verdict, of which the probability is $1-u$; and on the second hypothesis, the verdict will be given if the juror gives a right verdict, of which the probability is u; and the

---

[1] This is easily verified; for on changing x into $x-1$ in the integral, and forming the expression $v_x y_{x-1}+(1-v_x)(1-y_{x-1})\div(n-1)$, there results an identical equation.

probabilities of these hypotheses before the verdict being respectively p and $1-p$ as before, we have

$$\varpi'_1=\frac{(1-u)p}{(1-u)p+u(1-p)},\qquad \varpi'_2=\frac{u(1-p)}{(1-u)p+u(1-p)}.$$

From the above value of ϖ_1, we obtain $\varpi_1-p=\frac{p(1-p)(2u-1)}{up+(1-u)(1-p)}$; a fraction which is positive or negative according as u is greater or less than $\frac{1}{2}$. Hence it appears that the guilt of the accused is only rendered more probable by the verdict guilty being pronounced, when the probability that the juror gives a correct verdict is greater than $\frac{1}{2}$. In like manner it is shewn that ϖ'_1 (the presumption of the guilt of the accused after a verdict of acquittal), is greater than p when u is less than $\frac{1}{2}$.

78. The *a priori* probability of the condemnation of the accused before he is put on his trial is $up+(1-u)(1-p)$; for there are two ways in which this condemnation may take place; first, if the accused be guilty, and the juror give a correct verdict, the probability of which concurrence is up; and, secondly, if the accused be innocent, and the juror give a wrong verdict, the probability of which is $(1-u)(1-p)$. Therefore, making $c=$ the probability of a verdict of condemnation, we have $c=up+(1-u)(1-p)$; and for a verdict of acquittal, $1-c=(1-u)p+u(1-p)$.

79. Let us next suppose that after the verdict of the first juror has been pronounced, the accused is put on his trial before a second juror, and let u_2 be the probability the second juror gives a correct verdict, and c_2 be the probability the accused will be pronounced guilty by him. After the verdict guilty has been pronounced by the first juror, the probability of the guilt of the accused is ϖ_1, and it is evident that c_2 will be found by substituting u_2 for u, and ϖ_1 for p in the above value of c, whence $c_2=u_2\varpi_1+(1-u_2)(1-\varpi_1)$. The probability of a verdict of condemnation by both jurors is cc_2; therefore, (observing that $\varpi_1=up\div c$), we have for this probability

$$cc_2=uu_2p+(1-u)(1-u_2)(1-p).$$

The probability of the guilt of the accused after a verdict of acquittal has been pronounced by the first juror being ϖ'_1, the probability of a verdict of acquittal being given by the second juror is $1-c_2=(1-u_2)\varpi'_1+u_2(1-\varpi'_1)$; therefore, (observing that $\varpi'_1=(1-u)p\div(1-c)$, we have for the probability of a verdict of acquittal by both jurors

$$(1-c)(1-c_2)=(1-u)(1-u_2)p+uu_2(1-p).$$

Adding the probability of a verdict of condemnation by both jurors, to that of acquittal by both, we have $uu_2+(1-u)(1-u_2)$ for the probability of both giving the same verdict. This result is independent of p, and is evidently true *a priori*, inasmuch as there are two ways in which the same verdict may be given, namely, when both jurors are right, and when both are wrong.

The probability of acquittal by the second juror, after a verdict of guilty by the first, is $1-c_2=(1-u_2)\varpi_1+u_2(1-\varpi_1)$; multiplying by c, and substituting for c and ϖ_1 their values, we have for the probability of a verdict of guilty by the first, and not guilty by the second,

$$c(1-c_2)=u(1-u_2)p+(1-u)u_2(1-p).$$

In like manner, if the accused has been acquitted by the first juror, the presumption of his guilt becomes ϖ'_1, and the probability of a verdict guilty by the second is $c_2=u_2\varpi'_1+(1-u_2)(1-\varpi'_1)$; therefore the probability of a verdict of not guilty by the first, and of guilty by the second is

$$(1-c)c_2=(1-u)u_2p+u(1-u_2)(1-p).$$

The sum of these two expressions gives for the probability of a discordant verdict, $u(1-u_2)+(1-u)u_2$.

80. If we now suppose $u=u_2$, and make $1-u=w$, the probability that the two jurors will agree in their verdict, whether they are both right or both wrong, is u^2+w^2; and the probability of a discordant verdict $uw+uw=2uw$. The sum of the two expressions is $u^2+2uw+w^2=(u+w)^2$; and therefore the probabilities of the different cases are respectively given by the development of the binomial $(u+w)^2$.

By pursuing this reasoning, it is easy to see that if there be any number h whatever of jurors, or voters on any question which admits only of simple affirmation or negation, all being supposed to possess the same integrity and knowledge, so that there is the same probability u of a correct decision in respect of each, the probablities of the different cases are found by the development of the binomial $(u+w)^h$. The probability of a correct verdict being pronounced unanimously is u^h; of an erroneous one being pronounced unanimously is w^h; and the probability that a correct verdict will be given by m of the jurors, and an erroneous one by n, is Uu^mw^n, where $U=\frac{1\,.\,2\,.\,3.\,\ldots.h}{1\,.\,2\,.\,3\ldots m\times 1\,.\,2\,.\,3\ldots n}$.

81. The probability that the accused will be pronounced guilty by m jurors, and acquitted by n, on the supposition that the value of u is the same for each juror, is thus found. There are two ways in which this event may take place; 1st, if the accused be guilty (the probability of which is p), and m jurors decide correctly, and n wrongly (the probability of which is Uu^mw^n); the probability of the condemnation taking place in this way is therefore Uu^mw^np. 2d, If the accused be innocent (the probability of which is q) and n jurors decide rightly, and m wrongly (the probability of which is Uu^nw^m); the probability of the event taking place in this way is therefore Uu^nw^mq. Let G therefore denote the whole probability of the verdict, and we have

$$G=U(u^mw^np+u^nw^mq).$$

Hence the probability that the accused will be condemned unanimously by a jury consisting of h jurors is u^hp+w^hq; and the probability that he will be unanimously acquitted u^hq+w^hp.

82. Suppose the accused to have been pronounced guilty by m jurors, and not guilty by n jurors, the probability of the verdict of the majority being correct is found from the formula in (49). Two hypotheses may be made: 1st, the accused is guilty; 2d, he is innocent. The probability P_1 of the observed event (the condemnation by m, and acquittal by n jurors) on the first hypothesis is Uu^mw^n; and the *a priori* probabilities of the two hypotheses (or the probabilities denoted by λ_1 and λ_2 in (49), being p and q; therefore if ϖ_1 denote the probability of the verdict being correct, that is, the probability of the first hypothesis after the verdict has been pronounced, and ϖ_2 the probability of its being wrong, we shall have (49)

$$\varpi_1=\frac{u^mw^np}{u^mw^np+u^nw^mq},\qquad \varpi_2=\frac{u^nw^mq}{u^mw^np+u^nw^mq}.$$

If the verdict has been pronounced unanimously, then $m=h$ and $n=0$, and the formulæ become

$$\varpi_1=\frac{u^hp}{u^hp+w^hq},\qquad \varpi_2=\frac{w^hq}{u^hp+w^hq}.$$

If $p=q=\frac{1}{2}$, and $m-n=i$, we have then

$$\varpi_1=\frac{u^{n+i}w^n}{u^{n+i}w^n+u^nw^{n+i}}=\frac{u^i}{u^i+w^i}.$$

But this is the probability of a verdict being correct which has been pronounced unanimously by i jurors; whence it follows that the probability of a decision rendered by a given majority being correct, is the same as that of a decision rendered unanimously by a jury equal in number to the difference between the majority and minority, and is therefore independent of the total number of jurors. This, however, is only true on the supposition that the value of u is known *a priori*; for if u be not absolutely known, the weight of the verdict depends on the ratio of the majority to the whole number of jurors. This is in accordance with common notions, for it will readily be admitted that a verdict given unanimously by a jury of 10 will be entitled to much more weight than one pronounced by a jury consisting of a large number, as 100, in which 55 are of one opinion, and 45 of the opposite. In this case, the opinion of the minority throws great doubt on the correctness of the verdict. It is to be observed, however, that the probability of a verdict being given by a small majority becomes less and less as the number of jurors is increased.

83. When the number who dissent from the opinion of the majority is unknown, and we merely know that the majority exceeds the minority by *at least i* jurors, the probability of the verdict being correct is found as follows. Suppose the verdict to be guilty. On the hypothesis that it is correct, the probability of the accused being found guilty by $h-x$, and not guilty by x jurors, is by the formula in (80), $\text{U}u^{h-x}w^x$. Now, if we give x successively all the values 0, 1, 2,...n, where $n=\frac{1}{2}(h-i)$, and assume U_0 to denote the value of U when $x=0$, U_1 its value when $x=1$, and so on; and also make W = the probability of the accused being pronounced guilty by $h-n$ *at least*, we shall have

$$\text{W}=\text{U}_0u^h+\text{U}_1u^{h-1}w+\text{U}_2u^{h-2}w^2\ldots\ldots+\text{U}_nu^{h-n}w^n.$$

In like manner, if W′ denote the probability of a verdict guilty by $h-n$ jurors *at least*, on the hypothesis that the accused is not guilty, we shall have,

$$\text{W}'=\text{U}_0w^h+\text{U}_1uw^{h-1}+\text{U}_2u^2w^{h-2}\ldots\ldots+\text{U}_nu^nw^{h-n};$$

whence, p and q being as above the *a priori* probabilities of the two hypotheses, the probability that the verdict guilty is correct, when pronounced by $h-n$ jurors at least, becomes $\text{W}p\div(\text{W}p+\text{W}'q.)$

84. It is evident that no application can be made of these formulæ without assigning arbitrary values to u and p, unless, indeed, we have data for determining their mean values from experience. With respect to p, we may assume, for the sake of shewing the general consequences of the formulæ, its value to be $\frac{1}{2}$; for it cannot well be supposed less than $\frac{1}{2}$, or that a person brought before a jury is more likely to be innocent than guilty; and if it much exceeds $\frac{1}{2}$ and approaches to unity, a verdict of guilty may be expected from any jury, however constituted. When a mean value of u cannot be determined from experience, the only way of obtaining numerical results, is to suppose u to have all possible values within given limits, and to integrate the equations between those limits. As it seems unreasonable to suppose that a juror is more likely to give a wrong verdict than a right one, we may assume that u cannot be less than $\frac{1}{2}$. Suppose, then, that u increases by infinitely small increments from $u=\frac{1}{2}$ to $u=1$, and let it be proposed to determine the probability that a decision is correct when the accused has been pronounced guilty by m jurors, and not guilty by n. Here an infinite number of hypotheses may be made respecting the value of u, and we must therefore have recourse to the formulæ in (51.) Let $u=x$ be one of those hypotheses, $\text{P}_x=$ the probability on that hypothesis of the event observed (that is, of the accused being pronounced guilty by m, and not guilty by n jurors,) $\varpi_x=$ the probability of the assumed hypothesis, and $\Pi=$ the mean probability of the correctness of the verdict from all the hypotheses. By the formulæ in (81) we have

$$\text{P}_x=\text{U}\{x^m(1-x)^np+x^n(1-x)^m(1-p)\},$$

and as all the hypotheses are supposed equally probable, we have (45) $\varpi_x=\text{P}_x\div\Sigma\text{P}_t$. But between the proposed limits $\Sigma\text{P}_x=p\int_{\frac{1}{2}}^{1}x^m(1-x)^ndx+(1-p)\int_{\frac{1}{2}}^{1}x^n(1-x)^mdx$; if, therefore, we make $p=\frac{1}{2}$, we shall have by reason of $\int_{\frac{1}{2}}^{1}x^n(1-x)^mdx=\int_{\frac{1}{2}}^{1}x^m(1-x)^ndx, \Sigma\text{P}_x=\frac{1}{2}\int_0^1x^m(1-x)dx$, and therefore

$$\varpi_x=\frac{x^n(1-x)^n+x^n(1-x)^m}{\int_0^1x^m(1-x)^ndx},$$

for the probability of the hypothesis. But (82) the probability on this hypothesis of the accused being guilty, is $\frac{x^m(1-x)^n}{x^m(1-x)^n+x^n(1-x)^m}$; multiplying this by the probability of the hypothesis, ϖ_x, we obtain for the probability of the verdict being correct $x^m(1-x)^n\div\int_0^1x^m(1-x)^ndx$; and, therefore, for the probability of the verdict being correct on all the hypotheses from $x=\frac{1}{2}$ to $x=1$,

$$\Pi=\frac{\int_{\frac{1}{2}}^{1}x^m(1-x)^ndx}{\int_0^1x^m(1-x)^ndx}.$$

Hence the probability that a verdict given by a majority m out of $m+n=h$ jurors is wrong, is

$$1-\Pi=\frac{\int_0^{\frac{1}{2}}x^m(1-x)^ndx}{\int_0^1x^m(1-x)^ndx},$$

which, on effecting the integrations by the formula in (51) becomes after reduction

$$1-\Pi=\frac{1}{2^{h+1}}\left\{1+\frac{h+1}{1}+\frac{(h+1)h}{1\cdot2}+\frac{(h+1)h(h-1)}{1\cdot2\cdot3}\ldots\ldots+\frac{(h+1)h(h-1)\ldots\ldots(h-n+2)}{1\cdot2\cdot3\ldots\ldots\ldots\ldots n}\right\}.$$

Assuming h (the number of jurors) $=12$, and making n successively 0, 1, 2, 3, 4, 5, the series gives

$$\frac{1}{8192},\quad\frac{14}{8192},\quad\frac{92}{8192},\quad\frac{378}{8192},\quad\frac{1093}{8192},\quad\frac{2380}{8192},$$

for the respective probabilities of the error of a verdict when pronounced unanimously by 12 jurors, by a majority of 11 to 1, of 10 to 2, of 9 to 3, of 8 to 4, and of 7 to 5. In the last case the probability of the error is nearly $=\frac{2}{7}$.

85. From these results it appears that the chance of a verdict being wrong which has been pronounced unanimously by twelve jurors is very small; but it is to be remarked, that they have been deduced on the supposition that the unanimity proceeds from agreement in the same opinion, and that the jurors are unbiassed by each other. In this country, where unanimity is compelled by law, the mean probability of a correct verdict can scarcely be considered as greater than that of a verdict pronounced by a simple majority; for, though in most cases the verdict may be supposed to represent the opinion of a larger majority than seven, it may happen, not unfrequently, that a smaller number than five, possessing greater energy or perseverance, may persuade the others into a surrender of their judgment. In fact, unless the presumption of the guilt of the accused be very great, it would scarcely be possible, without concert, to procure an unanimous verdict in any case. It is also to be observed, that the assumption of all values of u from $\frac{1}{2}$ to 1 being equally probable, may lead to results widely different from the truth. The mean value of u, which depends on the general intelligence of the class of persons from amongst whom the lists of jurors are made up, can only be rightly determined from data furnished by experience. One of the elements, however, which require to be known for this purpose, is the number of jurors who concur in and dissent from, the verdict. The forced unanimity of the law renders it impossible to obtain this element from the records of the English courts; but in France and Belgium, where the majority and minority are known and recorded, the same obstacle does not exist, and the "*Comptes Généraux de l'Administration de la Justice Criminelle*," published by the French Government, have enabled Poisson to deduce mean values of u and p for that country, and consequently to obtain the necessary data for one of the most interesting applications of the theory of Probabilities. The general results were as follows: During

the six years from 1825 to 1830 inclusive, the system of criminal legislation in France underwent no change; the jury consisted of 12, and a simple majority was only required to concur, though when it happened that the majority was the least possible, the Court had power to overrule the verdict. On comparing, according to the rules of the theory, the verdicts given in the cases tried before the criminal courts during those six years, it was found that for the whole of France, the probability (u) of a juror giving a correct verdict was a little greater than $\frac{2}{3}$ with respect to crimes against the person, and nearly equal to $\frac{15}{17}$ with respect to crimes against property; without distinction of the species of crime, it was found to be a very little below $\frac{3}{4}$. The other element, the probability (p) of the guilt of the accused before the trial, was found not much to exceed $\frac{1}{2}$ (being between 0.53 and 0.54) with respect to crimes against the person, while it a little exceeded $\frac{2}{3}$ in respect of crimes against property. Without distinction of crime, its value was very nearly 0.64.

86. On substituting these values of u and p (namely $u=\frac{3}{4}$, $p=.64$, whence $w=\frac{1}{4}$, $q=.36$) in the formula in (81), and making $m=7$, $n=5$, and consequently $U=\frac{1\,.\,2\,.\,3\ldots\ldots 12}{1\,.\,2\,.\,3\ldots 7\times 1\,.\,2\,.\,3\ldots 5}=792$, we have $G=\frac{792}{4^{12}}(3^7\times .64+3^5\times .36)=.07$ nearly. Hence it may be expected, that in a hundred trials it will happen only seven times that the accused will be pronounced guilty by the smallest possible majority. If $m=12$, and $n=0$, we shall have $u^h p+w^h q=.02027=\frac{1}{50}$ nearly, for the probability of an unanimous verdict of guilty, and $u^h q+w^h p=.0114$ for the probability of an unanimous verdict of not guilty.

Making the same substitutions in the formula in (82), we have for the probability of a verdict guilty being correct, from which 5 jurors out of 12 dissent, $\varpi_1=\frac{16}{17}$; and $\varpi_2=\frac{1}{17}$ for the probability of its being wrong.

Substituting the same values in the series represented by W and W′ in (83), and supposing n to have all values from $n=0$ to $n=5$, there results $W=\frac{3^7}{4^{12}}\times 7254$, $W'=\frac{1}{4^{12}}\times 239122$, whence $\frac{Wp}{Wp+Wq}=\frac{126915984}{127992033}=\frac{118}{119}$ nearly. This is the probability that a verdict guilty, pronounced by a majority of seven against five *at least*, is correct. The probability of the same verdict being wrong, is therefore $\frac{1}{119}$; so that out of 119 verdicts, respecting which we know nothing else, than that seven at least of the jury concurred in finding the accused guilty, we may expect one to be wrong, or that one person out of 119 so condemned will be innocent.

SECT. VIII. OF THE SOLUTION OF QUESTIONS INVOLVING LARGE NUMBERS.

87. The probabilities of the different compound events which can result from the combination of any number of simple events, E_1, E_2, E_3, &c. being (13) measured respectively by the several terms of the developement of the multinomial $(p+q+r+\&c.)^h$, the most probable of those compound events will be that which corresponds to the term having the greatest numerical value. Let us consider the case of two simple contrary events E and F, the probabilities of which are respectively p and q, and suppose the number of occurrences to be 4. Neglecting the order of occurrence, the different combinations, with their respective probabilities, are the following:

$$\begin{array}{ccccc} \text{EEEE,} & \text{EEEF,} & \text{EEFF,} & \text{EFFF,} & \text{FFFF,} \\ p^4, & 4p^3q, & 6p^2q^2, & 4pq^3, & q^4. \end{array}$$

Now it is evident that the numerical values of these probabilities depend on the ratio of p to q, as well as on the coefficient by which they are multiplied, and that values may be given to p and q, such that any one of the terms may be made the greatest or the least in the series. If we suppose $p=q$, and consequently $p=\frac{1}{2}$, $q=\frac{1}{2}$, (since $p+q=1$) the probabilities of the different cases become respectively

$$\tfrac{1}{16},\quad \tfrac{4}{16},\quad \tfrac{6}{16},\quad \tfrac{4}{16},\quad \tfrac{1}{16};$$

whence it appears, that the most probable combination is that which corresponds to $6p^2q^2$, or in which each of the simple events occurs twice, the probability of this combination being $\frac{6}{16}$, while that of either of the simple events occurring four times in succession is only $\frac{1}{16}$.

When the number of trials is 5, the probabilities of the several cases are respectively

$$p^5,\quad 5p^4q,\quad 10p^3q^2,\quad 10p^2q^3,\quad 5pq^4,\quad q^5,$$

which, when $p=q$, become

$$\tfrac{1}{32},\quad \tfrac{5}{32},\quad \tfrac{10}{32},\quad \tfrac{10}{32},\quad \tfrac{5}{32},\quad \tfrac{1}{32},$$

so that there are two different combinations equally probable, namely, that in which E occurs three times and F twice, and that in which E occurs twice and F three times; and of the six possible combinations these two are the most probable, having in their favour a number of chances twice as great as the two cases in which one of the events occurs only once, and the other four times, and ten times greater than the two cases in which either of the simple events occurs in each of the five trials.

From these two instances it may be inferred in general, that when h is an even number, the most probable compound event is that of which the probability is represented by the middle term of the developement of $(p+q)^h$; and that when h is an odd number, there are two compound events equally probable, and more probable than any other, namely, those corresponding to the terms which occupy the middle of the series, supposing in both cases $p=q$. This supposition gives $(p+q)^h=(1+1)^h(\frac{1}{2})^h$; therefore in the case in which h is an even number, the general expression for the greatest term is

$$\frac{h(h-1)(h-2)\ldots\ldots(h-\frac{1}{2}h+1)}{1\,.\,2\,.\,3\quad\ldots\ldots\quad\frac{1}{2}h}(\tfrac{1}{2})^h;$$

and when h is odd, the general expression for either of the two equal terms, which are greater than any of the other terms, is

$$\frac{h(h-1)(h-2)\ldots\ldots\{h-\frac{1}{2}(h+1)+1\}}{1\,.\,2\,.\,3\quad\ldots\ldots\quad\frac{1}{2}(h+1)}(\tfrac{1}{2})^h.$$

88. When p and q are unequal, the greatest term of the expansion of $(p+q)^h$ will not occupy the middle of the series, but its place may be found by comparing two consecutive terms. Let $h=m+n$. The general term of the series then becomes

$$\frac{1\,.\,2\,.\,3\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots\ldots m\times 1\,.\,2\,.\,3\ldots\ldots n}p^m q^n;$$

and the term immediately preceding is

$$\frac{1\,.\,2\,.\,3\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots\ldots(m+1)\times 1\,.\,2\,.\,3\ldots\ldots(n-1)}p^{m+1}q^{n-1}.$$

Dividing the first of these by the second, we get for the quotient $(m+1)q\div np$, which, therefore, is the ratio of two consecutive terms taken at any part of the series. If this ratio be greater than 1, the term which has been taken as the dividend is greater than the preceding one which has been taken as the divisor; and it is evident that the terms must go on increasing, from the beginning of the series, so long as the ratio in question is greater than 1. But if the ratio be less than 1, the preceding term is greater than the succeeding, and the terms will become less and less as they are nearer the end of the series. Let $(m+1)q\div np=1$; then, since $p+q=1$, and $m+n=h$, we have $n=(h+1)q$, and consequently the ratio of any term to the next preceding is greater or less than 1 according as n is less or greater than $(h+1)q$. Now n is necessarily a whole number; therefore if $(h+1)q$ be a whole number, take $n=(h+1)q$, and the two terms of the series given by the expansion of $(p+q)^h$, in which the exponents of q are $n-1$ and n, will be equal to each other, and each greater than any other term of the series. But if $(h+1)q$ be not a whole number, let $(h+1)q-x$ be the nearest whole number *less* than $(h+1)q$, and make $n=(h+1)q-x$; then the greatest term of the developement will be that in which the exponent of q is n.

Since $n=(h+1)q-x$, we have $q=(n+x)\div(h+1)$, whence $p=1-\frac{n+x}{h+1}=\frac{m+1-x}{h+1}$, and therefore $\frac{q}{p}=\frac{n+x}{m+1-x}$. Now x is by hypothesis less than 1, therefore if m and n are large numbers, we have, very nearly, $q:p=n:m$; or, since $m+n=h$, $m=hp$, $n=hq$. It follows therefore, that the greatest term of the developement of the binomial $(p+q)^h$ is that in which the exponents of p and q are to each other in the ratio of p to q, or more nearly in that ratio than are any other two numbers whose sum is h. In other words, the most probable combination of two simple events, E and F, in any number of trials, is that in which the number of occurrences of E is to the number of occurrences of F in the ratio of their respective probabilities.

89. In the same manner it may be shewn, that when there are more than two simple events, of which one must occur in every trial, the most probable result of any number of trials is that combination in which the number of repetitions of each simple event is in proportion to its probability in a single trial. Thus, the probabilities of the simple events being respectively p, q, r, &c. the most probable compound event is that whose probability is expressed by that term of the expansion of $(p+q+r+\&c.)^h$, which has for its argument p^{hp}, q^{hq}, r^{hr}, &c.

90. Having determined the form of the greatest term of the series, we have next to find a method of approximating to its numerical value; for its coefficient containing the product of the natural numbers from 1 to h inclusive, its direct calculation becomes impracticable even when h is only a moderately large number. The theorem which gives the approximate value of this product is known by the name of *Stirling's Theorem*, having been discovered by that mathematician. As its investigation is a matter of pure analysis, we shall not stop to give it here, but refer the reader to the *Treatise on Differences and Series*, by Sir John Herschel, in the translation of Lacroix's *Elementary Treatise on the Differential and Integral Calculus*, p. 568.[1] The theorem is as follows: Let x be any number, then

$$1\,.\,2\,.\,3\ldots\ldots x=x^x e^{-x}\sqrt{2\pi x}\left(1+\frac{1}{12x}+\frac{1}{288x^2}+\&c.\right)$$

where e is the number of which the Napierean logarithm is unit, or the number 2·71828, and π the ratio of the circumference of a circle to the diameter, or 3·14159.

When x is a large number, the term divided by $12x$ becomes very small, and the series within the brackets may be considered as equal to unity. In this case, then, the formula becomes

$$1\,.\,2\,.\,3\ldots\ldots x=x^x e^{-x}\sqrt{2\pi x},$$

which gives a sufficient approximation in most cases. If, for example, $x=1000$, the result will be within a 12000th part of the truth.

Now, let E and F be two events of such a nature that the one or the other must happen in every trial; let p and q be their respective probabilities, and P the probability that in $m+n=h$ trials, E will happen m times and F n times; then by (12) we have

$$P=\frac{1\,.\,2\,.\,3\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots\ldots m\times 1\,.\,2\,.\,3\ldots\ldots n}p^m q^n.$$

When m, n, and h are large numbers, the value of this coefficient may be computed from the above formula, which gives

$$1\,.\,2\,.\,3\ldots\ldots h=h^h e^{-h}\sqrt{2\pi h},$$
$$1\,.\,2\,.\,3\ldots\ldots m=m^m e^{-m}\sqrt{2\pi m},$$
$$1\,.\,2\,.\,3\ldots\ldots n=n^n e^{-n}\sqrt{2\pi n},$$

whence

$$P=\frac{h^h e^{-h}\sqrt{h}}{m^m n^n e^{-(m+n)}\sqrt{(2\pi mn)}}p^m q^n=\left(\frac{hp}{m}\right)^m\left(\frac{hq}{n}\right)^n\sqrt{\frac{h}{2\pi mn}}.$$

This expression represents any term of the series $(p+q)^h$. The greatest term, which corresponds to the most probable result, is (88) that in which m and n are to each other in the ratio of p to q, or when $m=hp$, and $n=hq$. Let the greatest term therefore be denoted by P_o, that is to say, let P_o be the chance of the most probable result of h trials, and we shall have

$$P_o=\sqrt{(h\div 2\pi mn)},\text{ or }P_o=\sqrt{(1\div 2\pi hpq)}.$$

This last formula shews that the absolute probability of that combination which has the greatest number of chances in its favour becomes less and less as the number of trials is increased; for the fraction $1\div h$, to the square root of which the probability is proportional, diminishes as h is increased.

91. As an example, suppose a shilling to be tossed 100 times in succession. In this case $p=q=\frac{1}{2}$, $hp=50$, $hq=50$, and the most probable result of the trials is 50 times head and 50 times tail. We have then $h=100$, $m=50$, and $\sqrt{(h\div 2\pi mn)}=1\div\sqrt{(50\pi)}$ for the measure of the probability that the event will happen in this way exactly. On calculation, this is found $=.07979$; whence it appears, that although 50 heads and 50 tails is a more probable result of 100 trials than any other combination which can be named, its absolute probability is measured by a very small fraction. The probability of the contrary event, or that there will not be thrown 50 heads and 50 tails exactly, is $1-.07979=.92021$, so that the odds against the event are about 92 to 8, or 23 to 2. Had the number of trials been 1000, the probability of 500 times head and 500 times tail exactly, though more likely to occur than any other combination, would have been found $1\div\sqrt{(500\pi)}$; that is to say, $\sqrt{10}$ times, or rather more than 3 times less than in the former case. In general, when the chances in favour of the simple events are equal, the probability of the combination which is more likely to happen than any other, is inversely proportional to the square root of the number of trials.

92. The formulæ in (90) enable us also to determine the ratio of the greatest term of the developement of $(p+q)^h$ to any other term of the series, and consequently the relation of the probabilities of the different compound events. Let $m:n::p:q$, whence $m=hp$ and $n=hq$, and let P_x denote the probability that in h trials the event E will occur $(m-x)$ times, and the event F $(n+x)$ times, the probabilities of the simple events E and F being respectively p and q. By (13) we have

$$P_x=\frac{1\,.\,2\,.\,3\ldots\ldots\ldots h}{1\,.\,2\,.\,3\ldots\ldots(m-x)\times 1\,.\,2\,.\,3\ldots\ldots(n+x)}p^{m-x}q^{n+x},$$

which by (90) becomes

$$P_x=\frac{h^h e^{-h}\sqrt{(2\pi h)}}{(m-x)^{m-x}e^{-(m-x)}\sqrt{2\pi(m-x)}\times(n+x)^{n+x}e^{-(n+x)}\sqrt{2\pi(n+x)}}$$

$\times p^{m-x}q^{n+x}$; whence, substituting $m\div h$ for p, and $n\div h$ for q, and leaving out the factors common to the numerator and denominator, we find,

$$P_x=\sqrt{\left(\frac{h}{2\pi}\right)}(m-x)^{-m+x-\frac{1}{2}}(n+x)^{-n-x-\frac{1}{2}}m^{m-x}n^{n+x}.$$

---

[1] Stirling's investigation of the theorem, or rather of its equivalent, to find the sum of the logarithms of a series of numbers in arithmetical progression, is given in his *Methodus Differentialis*, p. 135.

Now $\log(m-x)^{-m+x-\frac{1}{2}}=(-m+x-\frac{1}{2})\log(m-x)$; and

$$\log(m-x)=\log m-\frac{x}{m}-\frac{x^2}{2m^2}-\&c.$$

therefore $\log(m-x)^{-m+x-\frac{1}{2}}=$

$$(-m+x-\tfrac{1}{2})\log m-(-m+x-\tfrac{1}{2})\left(\frac{x}{m}+\frac{x^2}{2m^2}+\&c.\right);$$

whence, neglecting terms divided by m^2, m^3, &c., m being supposed to be a large number in comparison with x,

$$\log(m-x)^{-m+x-\frac{1}{2}}=(-m+x-\tfrac{1}{2})\log m+x-\frac{x^2}{2m}+\frac{x}{2m};$$

therefore, on passing to numbers,

$$(m-x)^{-m+x-\frac{1}{2}}=m^{-m+x-\frac{1}{2}}\times e^{x-\frac{x^2}{2m}}\times e^{\frac{x}{2m}};$$

or, since $e^{\frac{x}{2m}}=1+\dfrac{x}{2m}+\dfrac{x^2}{2\,.\,4m^2}+\&c.$

$$(m-x)^{-m+x-\frac{1}{2}}=m^{-m+x-\frac{1}{2}}e^{x-\frac{x^2}{2m}}\left(1+\frac{x}{2m}\dots\right).$$

In like manner, by changing m into n, and x into $-x$, we get

$$(n+x)^{-n-x-\frac{1}{2}}=n^{-n-x-\frac{1}{2}}e^{-x-\frac{x^2}{2m}}\left(1-\frac{x}{2n}\dots\right).$$

Multiplying the first of these two expressions by m^{m-x}, and the second by n^{n+x}, we have

$$(m-x)^{-m+x-\frac{1}{2}}\times m^{m-x}=m^{-\frac{1}{2}}e^{x-\frac{x^2}{2m}}\left(1+\frac{x}{2m}\dots\right)$$

$$(n+x)^{-n+x-\frac{1}{2}}\times n^{n+x}=n^{-\frac{1}{2}}e^{-x-\frac{x^2}{2n}}\left(1-\frac{x}{2n}\dots\right),$$

whence, substituting these values in that of P_x, and neglecting the quantity divided by mn,

$$P_x=\sqrt{\left(\frac{h}{2\pi mn}\right)}\,e^{-\frac{x^2}{2m}-\frac{x^2}{2n}}=\sqrt{\left(\frac{h}{2\pi mn}\right)}\,e^{-\frac{hx^2}{2mn}}.$$

The term of the series $(p+q)^h$ which corresponds to this value of P_x is that which is x places to the right of the greatest term; and it has been shewn, (90), that the greatest term has for its expression $\sqrt{(h\div 2\pi mn)}$; therefore the greatest term being denoted, as before, by P_o, and the term which comes after it x places by P_x, we have

$$P_x=P_oe^{-hx^2\div 2mn},$$

that is to say, the probability the event E will happen m times and fail n times in $m+n$ trials, is to the probability of its happening $(m-x)$ times and failing $(n+x)$ times in the ratio of 1 to $e^{-hx^2\div 2mn}$.

Since the numbers m and n enter symmetrically into the expression $e^{-hx^2\div 2mn}$, it is evident that the result would have been the same if, instead of seeking the ratio of the greatest term to that which succeeds it by x places, we had sought the ratio of the greatest term to that which precedes it by x places. Hence if the most probable result of $m+n$ trials be that E will happen m times and fail n times, the probability that it will happen $m-x$ times and fail $n+x$ times is the same as the probability that it will happen $m+x$ times and fail $n-x$ times.

The following example will suffice to shew the application of the formula: A die is thrown 6000 times, required the probability that the number of aces turned up will be exactly 960?

Here p, the chance of throwing ace, is $\frac{1}{6}$, $q=\frac{5}{6}$, and $h=6000$; whence $m=hp=1000$, and $n=hq=5000$. We have first to find P_o, the chance of the most probable result, or of 1000 aces. By (90), $P_o=\sqrt{(h\div 2\pi mn)}$; whence, substituting the above values, $P_o=\sqrt{3}\cdot\sqrt{(5000\times 3.14159)}$. On performing the operation indicated by the logarithmic tables, we get $\log P_o=8.14050$, whence $P_o=.0138$.

The calculation of $e^{-hx^2\div 2mn}$ is as follows: Assume $t^2=hx^2\div 2mn$. We have $x=1000-960=40$.

$$\begin{array}{r}
\log 40=1.60206\\
2\\
\hline
3.20412\\
\log h=\log 6000=3.77815\\
\hline
\log hx^2=6.98227\\
\log 2mn=\log 10{,}000{,}000=7\quad\\
\hline
\log t^2=9.98227\\
\log e=.43429,\ \log .43429=9.63778\\
\hline
\log(t^2\times .43429)=9.62005\\
t^2\times .43429=t^2\log e=\ .41692\\
-t^2\log e=9.58308\\
\text{add }\log P_o=8.14050\\
\hline
\log P_x=7.72358
\end{array}$$

therefore $P_x=.0053$, which is the chance of 960 aces exactly. The odds against this event are therefore 9947 to 53, or nearly 188 to 1.

93. When h, m, and n are large numbers, and x is small, the exponential $e^{-hx^2\div 2mn}$ differs little from unity, and it decreases slowly as x increases, so long as x is small in comparison of m and n. Suppose $m=n$ and $x=\sqrt{m}$, it becomes $e^{-1}=\dfrac{1}{e}=\dfrac{1}{2\cdot 7182818}$; so that if we assume $m=100$, the 10th term before or after the greatest would still exceed the 3d part of the greatest. But when x becomes greater than $\sqrt{m}$ or $\sqrt{n}$ the exponential, and consequently also the terms which are multiplied by it, begin to diminish with great rapidity, and the diminution is more rapid as x increases. If $m=n=100$, and $x=50$, then the exponent $hx^2\div 2mn=25$, so that $e^{-hx^2\div 2mn}$, $=1\div e^{25}$, a quantity which is altogether insensible. We may therefore conclude generally that when h is a large number, the principal terms of the developement of $(p+q)^h$ are those which are near the greatest term, and that h may be taken so large that the terms towards the beginning or end of the series may at length become smaller than any assignable quantity.

94. From the proposition which has now been demonstrated it follows, that although the probability of that particular compound event which has the greatest number of chances in its favour is very small when the number of trials is great, yet on account of the rapid diminution of the terms towards the beginning and end of the series, the sum of a comparatively small number of terms taken on both sides of the greatest, may be very much greater than all the remaining terms of the series; and, consequently, there will be a very great probability that the compound event will be represented by one or other of those terms. This consideration leads us to one of the most important questions in the theory, namely, to determine the probability that in a large number of trials, h, an event E, which must either happen or fail in each trial, and of which the chance of happening in any trial is p, will happen not less than $hp-l$ times, and not oftener than $hp+l$ times; or, making $hp=m$, $hq=n$, to determine the probability that the number of occurrences of E will be included between the limits $m\pm l$.

Let x be any number between 0 and l. Then (92) the probability that E will occur $(m-x)$ times and fail $(n+x)$ times is $P_x=P_oe^{-hx^2\div 2mn}$(where $P_o=\sqrt{(h\div 2\pi mn)}$. Now if in this expression we make x successively equal to each of the numbers 0, 1, 2,…l, we shall have the respective probabilities of E happening m, $m-1$, $m-2$,……$m-l$ times in h trials; and the sum of these probabilities will be the probability that E happens *not oftener* than m times, and *not seldomer* than $m-l$ times. The same suppositions with respect to x will give the probabilities of E happening $m, m+1, m+2, \ldots m+l$ times, the sum of which will be the probability that E happens *not seldomer* than m times, and *not oftener* than $m+l$ times. Adding, therefore, those two sums, and deducting P_o the probability which corresponds to $x=0$, on account of its being included in each sum, and therefore having been counted twice, the result will be the sum of the terms of the binomial $(p+q)^h$ comprised between, and including, the two terms of which the first has for a factor p^{m+l}, and the last p^{m-l}, and will therefore express the probability that the number of occurrences of E will fall within the limits $m \pm l$. Let this probability be denoted by R, and let SP_x represent the sum of all the values of P_x obtained by substituting successively 0, 1, 2, 3,...l for x, we then have $R=2SP_x-P_o$, whence, writing for P_x and P_o, their values,

$$R=2S\sqrt{\left(\frac{h}{2\pi mn}\right)}e^{-\frac{hx^2}{2mn}}-\sqrt{\frac{h}{2\pi mn}}.$$

95. In order to find an approximate value of this expression we must have recourse to a formula first given by Euler for converting sums of the kind denoted by S into definite integrals (for which see Lacroix, *Traité du Calcul Différentiel et Intégral*, tom. iii. p. 136, or Herschel's *Treatise on Differences*, p. 513). Assuming u to denote a function of x, the formula is as follows:

$$Su=\int u\,dx+\frac{1}{2}u+\frac{1}{1.2.6}\frac{du}{dx}+\text{\&c.}+\text{constant.}$$

On making $u=P_x=P_o e^{-hx^2 \div 2mn}$, we find $\frac{du}{dx}=-\frac{P_o hx}{mn}$ $e^{-hx^2 \div 2mn}$; therefore, if we suppose x to be not greater than $\sqrt{m}$ or $\sqrt{n}$, this differential coefficient is of the order $1 \div h$, (as may be easily shewn by substituting hp for m, and hq for n), and may be rejected, since h is supposed to be a very large number. The above equation therefore becomes

$$SP_x=P_o\int e^{-hx^2 \div 2mn}dx+\tfrac{1}{2}P_o e^{-hx^2 \div 2mn}+\text{constant};$$

and on supposing $x=0$ this gives $0=-\frac{1}{2}P_o+\text{constant}$, therefore the constant is equal to $\frac{1}{2}P_o$, and we have

$$SP_x=P_o\int e^{-hx^2 \div 2mn}dx+\tfrac{1}{2}P_o e^{-hx^2 \div 2mn}+\tfrac{1}{2}P_o.$$

Assume $t=x\sqrt{(h \div 2mn)}$, whence $dt=dx\sqrt{(h \div 2mn)}$; substitute these in the above equation, and it becomes by reason of $P_o=\sqrt{(h \div 2\pi mn)}$,

$$SP_x=\frac{1}{\sqrt{\pi}}\int e^{-t^2}dt+\tfrac{1}{2}P_o e^{-t^2}+\tfrac{1}{2}P_o,$$

whence, from the equation $R=2SP_x-P_o$, we obtain

$$R=\frac{2}{\sqrt{\pi}}\int e^{-t^2}dt+P_o e^{-t^2}.$$

The integral in this expression must be taken between the limits $x=0$ and $x=l$. When $x=0$ we have also $t=0$, and when $x=l$, then $t=l\sqrt{(h \div 2mn)}$; therefore assuming τ for the limiting value of t, that is, making $\tau=l\sqrt{(h \div 2mn)}$, and therefore $l=\tau\sqrt{(2mn \div h)}$, there results

$$R=\frac{2}{\sqrt{\pi}}\int_0^\tau e^{-t^2}dt+P_o e^{-\tau^2}$$

for the probability that the number of occurrences of E will fall between $m \pm \tau\sqrt{(2mn \div h)}$; or, replacing m and n by hp and hq, the probability that the number of occurrences of E will fall within the limits $hp \pm \tau\sqrt{(2hpq)}$, or be equal to one of those limits.

This expression for R has been found by neglecting quantities of the order of smallness $1 \div h$; consequently the greater the value of h the more nearly it approaches to accuracy, but it is only rigorously true when h is infinite.

96. The integral $\int e^{-t^2}dt$ is computed as follows. Developing the exponential e^{-t^2} in a series of the ascending powers of t^2, and integrating the successive terms between the limits $t=0$ and $t=\tau$, we find

$$\int_0^\tau e^{-t^2}dt=\tau-\frac{\tau^3}{1.3}+\frac{\tau^5}{1.2.5}+\frac{\tau^7}{1.2.3.7}+\text{\&c.};$$

a series which converges rapidly when τ is less than unity. In the contrary case, however, or when τ is greater than unity, the series is divergent, and it is necessary to proceed by a different method. Let the factor e^{-t^2} be multiplied and divided by t; we have then

$$\int e^{-t^2}dt=\int\frac{1}{t}e^{-t^2}t\,dt,$$

and on integrating by parts

$$\int\frac{1}{t}e^{-t^2}t\,dt=-\frac{e^{-t^2}}{2t}-\tfrac{1}{2}\int\frac{1}{t^2}e^{-t^2}dt.$$

Repeating the same process on the last integral, and so on with the last after each succeeding integration, the following series is obtained,

$$\int e^{-t^2}dt=-\frac{e^{-t^2}}{2t}\left\{1-\frac{1}{2t^2}+\frac{3}{2^2t^4}-\frac{3\cdot5}{2^3t^6}+\text{\&c}\right\}.$$

When $t=$ infinity the right hand side of this equation becomes 0; whence between the limits $t=\tau$ and $t=$ infinity, we have

$$\int_\tau^\infty e^{-t^2}dt=-\frac{e^{-\tau^2}}{2\tau}\left\{1-\frac{1}{2\tau^2}+\frac{3}{2^2\tau^4}-\frac{3\cdot5}{2^3\tau^6}+\text{\&c}\right\},$$

a series which converges very rapidly when τ is greater than unity. Now the value of a definite integral between 0 and infinity is obviously equal to its two parts, of which the first is taken between 0 and τ, and the second between τ and infinity; that is to say,

$$\int_0^\tau e^{-t^2}dt=\int_0^\infty e^{-t^2}dt-\int_\tau^\infty e^{-t^2}dt.$$

But $\int_0^\infty e^{-t^2}dt$ is well known[1] to have for its expression $\frac{1}{2}\sqrt{\pi}$, therefore

$$\int_0^\tau e^{-t^2}dt=\tfrac{1}{2}\sqrt{\pi}-\int_\tau^\infty e^{-t^2}dt,$$

so that the integral may be computed from either of the above series, according as τ is less or greater than 1.

The integral $\int e^{-t^2}dt$ is of great importance in the higher mathematics. It occurs in the investigation of the path of a ray of light through the atmosphere, and of the law of the diffusion of heat in the interior of solid bodies, as well as in the determination of the degree of reliance that may be placed on the results of astronomical observations, and generally in most of the more difficult and important applications of the theory of probabilities. A table of its values from $t=0$ to $t=3$, for intervals each $=\cdot01$, was given by Kramp, at the end of his *Analyse des Refractions Astronomiques*, Strasburg, 1799. In the *Berliner Astronomisches Jahrbuch* for 1834, there is also a table of its values from $t=0$ to $t=2$ (for the same intervals) multiplied by $2 \div \sqrt{\pi}$, with their first and second differences for the purpose of facilitating interpolation. This last table, which appears to have been derived from that of Kramp, and which is immediately applicable in the calculation of the probability R, we have extended to $t=3$, and given at the end of the present article. As the function which is thus tabulated will occur frequently in what follows, we shall in future, for convenience in printing, denote it by Θ, that is to say, we shall assume

---

[1] The formula $\int_0^\infty e^{-t^2}dt=\frac{1}{2}\sqrt{\pi}$ is ascribed by Gauss (*Theoria Motus Corporum Cœlestium*, p. 212,) to Laplace. On making $e^{-t^2}=z$, the integral is transformed into $\frac{1}{2}\int dz\left(\log\frac{1}{z}\right)^{-\frac{1}{2}}$ between the limits $z=0$ and $z=1$, the value of which $=\frac{1}{2}\sqrt{\pi}$, had been given by Euler, long before, in the *Petersburg Memoirs*. See Legendre, *Exercises du Calcul Intégral*, tom. i. p. 301.

$$\Theta=\frac{2}{\sqrt{\pi}}\int_0^\tau e^{-t^2}dt=1-\frac{2}{\sqrt{\pi}}\int_\tau^\infty e^{-t^2}dt,$$

the two forms being equivalent in consequence of the above equation.

97. Some very important conclusions follow immediately from the formula in (95). The quantity R denotes the probability that in a very great number of trials h, the event E, of which the *a priori* probability in any trial is p, will occur not seldomer than $hp-l$ times, and not oftener than $hp+l$ times, or that the number of its occurrences will be included between the limits $hp\pm l$, or at least be equal to one of those limits. Hence R also denotes the probability that the ratio of the occurrences of E to the whole number of trials, will be included within the limits $p\pm l\div h$. We have assumed $\tau=l\sqrt{(h\div 2mn)}$; but $m=hp$ and $n=hq$; therefore $\tau=l\div\sqrt{(2hpq)}$, whence $l=\tau\sqrt{(2hpq)}$, and consequently $l\div h=\tau\sqrt{(2pq\div h)}$. Now, if we suppose τ to be constant, so that the probability expressed by R may remain the same, then p and q being given, l is proportional to the square root of h, and consequently the greater the number of trials the smaller will l be in proportion to that number. Thus, if the number of trials be 1000, and we have a given probability R that the number of occurrences of E will not differ more than 10 from the number which is the most probable of all (that is, from $1000\,p$), then if we take 100,000 trials, we shall have the same probability R that the number of occurrences of E will not differ more than $10\times\sqrt{100}=100$ from the most probable number. But a difference of 10 in 1000 is 1-100th of the whole, whilst a difference of 100 in 100,000 is 1-1000th of the whole, and thus the ratio of l to h becomes smaller and smaller, or the ratio of the occurrences of E to the whole number of trials approaches nearer and nearer to p, as the number of trials is increased; and the experiments may be repeated until the difference between p and $p\pm l\div h$, in respect of a given probability R which may be as great as we please, shall be less than any assignable quantity.

If, on the other hand, we suppose $l\div h$ to be constant, then τ is proportional to the square root of the number of trials. But as τ increases, Θ, and consequently R, approaches nearer and nearer to unity, (and it may be seen, by referring to the table, that it is only necessary to have $\tau=3$ in order to have $\Theta=\cdot9999779$); whence the number of trials h may always be increased until we obtain a probability approaching as nearly to certainty as we please, that the number of occurrences of E will be comprised within the given limits $(hp\pm l)$; or, which is the same thing, that the ratio of the number of occurrences of E to the whole number of trials, shall not differ from p, the probability of E in a single trial, more than a given quantity $l\div h$ which may be less than any assigned fraction. This is the celebrated theorem which was demonstrated by James Bernoulli in the *Ars Conjectandi.*

98. The application of the preceding results to numerical examples, is rendered extremely easy by means of the table of the values of Θ. From the formula in (95) we have the probability

$$R=\Theta+P_0 e^{-\tau^2},$$

that the occurrences of E in h trials will fall within the limits $hp\pm l$, the relation between l and τ being given by the equation $l=\tau\sqrt{(2hpq)}$. If, therefore, we suppose l to be given, τ becomes known, and the corresponding value of Θ is found from the table; and, conversely, if Θ be assumed, τ is given by the table, whence the correspondiug limits l are deduced. With respect to the quantity $P_0 e^{-\tau^2}$, we may observe that it denotes the probability that the number of occurrences of the event E will be $hp+l$ or $hp-l$ precisely (92), and is therefore always a very small fraction when h is a large number (90). It may be regarded as a correction of Θ, which in most cases might be omitted without sensibly affecting the result; but when h is not very large, or l is a small number, it becomes necessary to take it into account. In such cases its value may be computed directly as in the example in (92); but this labour may be avoided by increasing τ, so as to include it within the limits of the integral Θ. Thus, let R be the probability that the number of arrivals of E will be included within the limits $hp\pm x$, and R′ the probability of the limits being $hp\pm(x+1)$, and let Θ and Θ' be respectively the correspondiug values of the integral. We have then, giving P_x the same signification as in (92), the two equations

$$R=\Theta+P_x,\quad R'=\Theta'+P_{x+1},$$

and the difference $R'-R$ of these two probabilities is obviously the double of the probability that the result of the trials will be either $(hp+x+1)$ times E, or $(hp-x-1)$ times E, exactly. But the chance of either of these events being P_{x+1}, we have therefore $R'-R=2P_{x+1}$. Now, when h is large, P_x and P_{x+1} are very small, and very nearly equal to each other, (their difference is in fact of the order of quantities omitted); hence $R'-R=\Theta'-\Theta$, and also $2P_{x+1}=2P_x$, and consequently $\Theta'-\Theta=2P_x$, or $P_x=\frac{1}{2}(\Theta'-\Theta)$. Substituting this value of P_x in the equation $R=\Theta+P_x$, we get $R=\frac{1}{2}(\Theta'+\Theta)$; so that if we take from the table the values of Θ' and Θ corresponding to l and $l+1$, half their sum will give R. But as the interval between Θ' and Θ in the table is always small, half their sum will not differ sensibly from the value of Θ corresponding to $l+\frac{1}{2}$, whence this value of Θ is equal to R, and we have the following rule for determining the limits corresponding to a given probability, or *vice versa* :—

When the limits are assumed, find τ from the equation $l+\frac{1}{2}=\tau\sqrt{(2hpq)}$; then the value of Θ in the table, corresponding to τ is the probability that in h trials the number of occurrences of the event E, the chance of which in a single trial is p, will lie within the limits $hp\pm l$ both inclusive. Conversely, when Θ is assumed, find the corresponding value of τ in the table, by means of which the limit l will be given by the equation $l+\frac{1}{2}=\tau\sqrt{(2hpq)}$. It is obvious, that if the limit l and the probability Θ be both assumed, then h may be determined from the same equation.

99. We will now give some examples of the application of the preceding formulæ.

Suppose $p=q=\frac{1}{2}$, and $h=200$, and let it be proposed to assign the limits within which there is a probability $=\frac{1}{2}$ that the number of occurrences of E will fall. In this case the equation $l+\frac{1}{2}=\tau\sqrt{(2hpq)}$ becomes $l+\frac{1}{2}=\tau\sqrt{100}=10\tau$. Now, it is easily found from the table that for $\Theta=\frac{1}{2}$ we have $\tau=\cdot4769$, whence $l+\frac{1}{2}=4\cdot769$, and $l=4\cdot269$. On tossing a shilling 200 times, it is therefore more than an even wager that head will turn up not seldomer than 95 times, and not oftener than 105 times.

Suppose $p=q=\frac{1}{2}$, $h=3600$, and let it be proposed to assign the probability that the number of occurrences of E will not exceed the limits 1800 ± 30. In this case the equation $l+\frac{1}{2}=\tau\sqrt{(2hpq)}$ becomes $30\cdot5=\tau\sqrt{(2\times900)}=30\tau\sqrt{2}$, whence $\tau=30\cdot5\div30\sqrt{2}=\cdot7189$; and the table gives $\Theta=\cdot6907=\frac{28}{41}$ nearly. Hence in tossing a shilling 3600 times, the odds are 28 to 13 that head will not turn up oftener than $1800+30=1830$ times, nor seldomer than $1800-30=1770$ times. Neglecting the second term of R (95) and taking simply $l=10\tau$, the table gives $\Theta=\cdot6827$, which is the solution given by Demoivre, p. 245.

Suppose $p=\frac{1}{6}$, $q=\frac{5}{6}$, and let it be proposed to determine how many trials must be made in order that it may be one to one that the number of occurrences of E will not differ more than 10 from the most probable number.

For $\Theta = \frac{1}{2}$ we have $\tau = {\cdot}4769$; therefore the equation $l + \frac{1}{2} = \tau\sqrt{(2hpq)}$ becomes $10{\cdot}5 = {\cdot}4769\sqrt{(10h \div 36)}$, whence $h = 3{\cdot}6(10{\cdot}5 \div {\cdot}4769)^2$. On computing this formula h is found $= 1745{\cdot}2$. Say 1746, $\frac{1}{6}$ of which is 291; and it follows that if a die be thrown 1746 times it is an even wager that the number of aces will fall between 291 ∓ 10, that is, between 281 and 301, or be equal to one of those numbers.

In (92) we found the probability to be ·0053, that in 6000 throws of a die the number of aces will be exactly 960. Let it now be proposed to assign the probability Θ, that in 6000 throws the number of aces will lie between 960 and 1040, that is, between 1000 ∓ 40. Here $h = 6000$, $p = \frac{1}{6}$, $q = \frac{5}{6}$, and $l = 40$; the equation of the limits therefore becomes $40{\cdot}5 = \tau\sqrt{(10000 \div 6)}$, whence $\tau = {\cdot}405\sqrt{6} = {\cdot}992$, corresponding to which the table gives $\Theta = {\cdot}8394$.

The following question is discussed by Nicolas Bernoulli in the Appendix to Montmort's *Analyse des Jeux de Hazard*, and is noticed by Demoivre and Laplace. From the observations of the births of both sexes in London during 82 years (from 1629 to 1711) it was found that the average number of children annually born in London, was about 14,000, and the ratio of the number of males to that of females, was nearly as 18 to 17, the average number of male births being 7200, and of female births 6800. In the year in which the greatest difference from this ratio took place, the actual numbers were 7037 males and 6963 females, so that the difference from the average amounted to 163. Assuming, then, the comparative facility of male and female births to be as 18 to 17, required the probability that out of 14000 children born, the number of males shall not be greater than 7363, nor less than 7037.

This question is evidently equivalent to the following:—Let 14000 dice, each having 35 faces, 18 white and 17 black, be thrown; what is the probability that the number of white faces turned up, will be comprised between the limits 7200 ± 163. We have therefore $h = 1400$, $p = \frac{18}{35}$, $q = \frac{17}{35}$, $l = 163$, and the formula $l + \frac{1}{2} = \tau\sqrt{(2hpq)}$ becomes $163.5 = \tau\sqrt{(2 \times 14000 \times 18 \times 17)} \div 35$, whence $\tau = 1{\cdot}955$. The corresponding value of Θ is found from the table $= {\cdot}9943$, which is the probability that the number of white faces shall not be greater than 7363, nor less than 7037. The odds in favour of the event are therefore 9943 to 57, or about 175 to 1.

100. We now proceed to consider the case in which the probabilities of the simple events are not known, *a priori*, but inferred from the results of experience. It was shewn in (52) that the probability Π of an event happening m' times, and failing n' times in h' trials, $(h' = m' + n')$, when it has been observed to happen m times, and fail n times in h previous trials, is expressed by this equation

$$\Pi = U' \frac{[m+m'][n+n'][h+1]}{[m][n][h+h'+1]}.$$

Now, when m, n, m', n', are large numbers, an approximate value of Π, more accurate in proportion as those numbers become larger, is obtained from Stirling's theorem (90), which for any number x gives $[x] = x^x e^{-x}\sqrt{(2\pi x)}$. Applying the theorem therefore to the expressions within the brackets in the above equation, and assuming

$$K = \frac{h+1}{h+h'+1}\sqrt{\frac{(m+m')(n+n')(h+1)}{mn(h+h'+1)}},$$

we obtain, in consequence of $m + n = h$,

$$\Pi = U'K \frac{(m+m')^{m+m'}(n+n')^{n+n'}(h+1)^h}{m^m n^n (h+h'+1)^{h+h'}}.$$

Let $m' = \theta m$, $n' = \theta n$, and consequently $h' = \theta h$; then taking $\frac{h^h}{(h+h')^{h+h'}}$ for $\frac{(h+1)^h}{(h+h'+1)^{h+h'}}$ (which may be done without sensible error, since h is by supposition a large number,) the equation becomes

$$\Pi = U'K \frac{m(1+\theta)^{m+m'} n(1+\theta)^{n+n'} h^h}{m^m n^n (1+\theta)^{h+h'}};$$

or, since $m + n = h$, $m' + m' = h'$,

$$\Pi = UK \frac{m^{m'} n^{n'} (1+\theta)^{h+h'}}{h^h (1+\theta)^{h+h'}} = UK\left(\frac{m}{h}\right)^{m'}\left(\frac{n}{h}\right)^{n'}.$$

Making the same substitutions in the expression denoted by K, we get, after reduction, $K = 1 \div \sqrt{(1+\theta)}$; whence,

$$\Pi = \frac{U'}{\sqrt{1+\theta}}\left(\frac{m}{h}\right)^{m'}\left(\frac{n}{h}\right)^{n'}.$$

The value of Π now found, is the probability that in a future series of trials the ratio of the occurrences of E to those of F will be the same as in the preceding trials, which are supposed to have been very numerous. If the chances of E and F had been given *a priori* equal to $m \div h$ and $n \div h$ respectively, the probability of m' times E, and n' times F in $m' + n'$ future trials would have been $P = U'\left(\frac{m}{h}\right)^{m'}\left(\frac{n}{h}\right)^{n'}$ by (12); hence (since $m' \div h' = m \div h$ and $n' \div h' = n \div h$), the relation between the probability P_o of that combination of simple events which has the greatest number of chances in its favour, when the chances of the simple events are known *a priori*, and the probability of the same combination when the chances of the simple events are only presumed from previous trials, is expressed by this equation,

$$\Pi = P_o \div \sqrt{(1+\theta)}.$$

101. When h' is very small in comparison of h, θ becomes a very small fraction, and may be neglected, and we have then $\Pi = P_o$. But when h' is a number comparable with h, Π is less than P_o; and it diminishes rapidly when θ exceeds 1. The reason of this is obvious. If the contents of the urn are not known *a priori*, however numerous the trials may have been there is only a presumption that the chance of drawing a white ball in a single trial is measured by $m \div h$; whereas, in the case of the ratio of the balls being previously known, the measure of the probability is certain. As an instance of the manner in which the probability of an assigned series of future events diminishes, when the probabilities of the simple events are inferred from experience, let us suppose $h' = h$, whence $\theta = 1$, and consequently $\Pi = P_o \div \sqrt{2} = {\cdot}7071 \times P_o$. Now it was shewn in (91) that if a ball be drawn at random 100 times from an urn which contains an equal number of black and white balls, the probability P_o, that the result will be 50 white balls, and 50 black, precisely, is ·07979. It follows therefore, that if the contents of the urn be unknown, and we can only judge of the relative numbers of the two sorts of balls it contains from having observed that in 100 trials there have been drawn 50 white balls and 50 black, the probability Π of that combination in 100 future trials, becomes $\cdot07979 \times {\cdot}7071 = {\cdot}05642$.

102. The result obtained in (100) enables us to determine the probability that the number of occurrences of E in h' future trials, will not differ in excess or defect from the most probable number, by more than a certain given number l. It has been shewn (95) that in the case of the probabilities p and q of the simple events being given *a priori*, if we determine τ from the equation $l = \tau\sqrt{(2hpq)}$, the formula

$$R = \Theta + \sqrt{(1 \div 2\pi hpq)}\, e^{-\tau^2}$$

gives the probability R that m will be comprised within the limits $hp \pm \tau\sqrt{(2hpq)}$; or, dividing by h, the probability that the ratio of m to h will be comprised within the limits

$p \pm \tau\sqrt{(2pq \div h)}$. Conversely[1], when p and q are not known, but the event E has been observed to happen m times in h trials, then

$$\mathrm{R} = \Theta + \sqrt{(h \div 2\pi mn)}\,e^{-\tau^2}$$

gives the probability R that p is comprised within the limits

$$\frac{m}{h} \pm \frac{\tau}{h}\sqrt{\frac{2mn}{h}}.$$

These limits approach more nearly to each other as h increases; and when h is a large number, the ratios $m \div h$, $n : h$ may be assumed, without sensible error, as the chances of E and F in computing the probable result of a future series of h' trials, provided, however, that h' (though absolutely a large number) be small relatively to h. When this condition is not fulfilled, the assumption of $m \div h$ and $n \div h$ as the *a priori* chances of E and F, might lead to considerable error; but an approximation to the limits corresponding to a given value of R may be obtained from the following considerations:—

Suppose a large number h of events to have been observed, and that the result of the observation gave m times E and n times F. Let a new series of h' trials be made, and *suppose* that in this new series p is the real chance of E and q of F; we have then a given probability R that the number of occurrences of E will fall within the limits $h'p \pm \tau\sqrt{(2h'pq)}$. Now, for p and q substitute the ratios observed in the first set of experiments, namely, $m \div h$ and $n \div h$, and the limits corresponding to R become

$$\frac{mh'}{h} \pm \frac{\tau}{h}\sqrt{(2h'mn)},$$

which, therefore, are the true limits on the hypothesis that the chance of E in a single trial is $m \div h$. But as this chance is not certain, but only presumed, the limits require to be extended in order that R may preserve the same value. Confining our attention to Θ, the first term of the expression for R (the second may be disregarded in the present approximation), let $h' = m' + n'$ and $m' : n' = m : n$, then Θ is the sum of the terms of the binomial $(p+q)^{h'}$ from that in which the exponent of p is $m' + l$ to that in which the exponent is $m' - l$. Now, when p and q are given *a priori*, the chance of m' times E and n' times F in h' trials is P_o; and when p and q are only presumed from the results of previous trials, the chance of the same combination is Π; and (100) Π is less than P_o in the ratio of 1 to $\sqrt{(1+\theta)}$. In like manner, the chance of each of the other combinations of E and F included in the integral Θ will be less in the case of p and q presumed, than in the case of p and q given, in the same ratio of 1 to $\sqrt{(1+\theta)}$. But it has been seen (93) that when h' is a large number, the terms of the developement of $(p+q)^{h'}$ which are nearest the greatest term, diminish at first very slowly; and, further, that only a small number of terms on each side of the greatest are required to be taken, since l is less than $\sqrt{m'}$ or $\sqrt{n'}$ (95); we may therefore, without sensible error, assume Θ to be proportional to the number of terms included in the summation, or that the value of Θ will not be changed if we include in the summation a number of terms greater in proportion as the value of each individual term is less. Hence it follows that the limits must be increased in the ratio of $\sqrt{(1+\theta)}$ to 1, and the value of Θ corresponding to τ will give the probability that the number of events E, in h' future trials, will be included between

$$\frac{mh'}{h} \pm \frac{\tau}{h}\sqrt{(2h'mn(1+\theta))}.$$

103. The following question may be proposed as an example of the application of the last formula. Out of a given number h of individuals taken at the age A, it has been observed that m are alive at the age A$+a$; required the probability that out of h' other individuals taken at the same age A the number who survive at the age A$+a$ will be included between $m' \pm l$, the ratio of m' to h' being the same as that of m to h.

To solve this question, we have to find τ from the equation $l = \frac{\tau}{h}\sqrt{(2h'mn(1+\theta))}$; and the corresponding value of Θ in the table, will give the required probability.

From the table given in the article MORTALITY, vol. xv. p. 555, it appears that out of 5642 individuals taken at the age 30, the number surviving at the age 50, according to the Carlisle Table, is 4397. Taking those numbers as an example, we have $h = 5642$, $m = 4397$, $n = 1245$; and assuming also $h' = 5642$, whence $\theta = 1$ and $\sqrt{(1+\theta)} = \sqrt{2}$, the equation of the limits becomes $l = \tau \times 62{\cdot}30$, Let it be proposed to determine l from the condition $\Theta = \frac{1}{2}$. In this case the table gives $\tau = {\cdot}4769$, and we have consequently $l = 29{\cdot}7$. Hence it appears, that if it has been observed that of 5642 individuals taken at the age of 30, 1245 die before reaching the age of 50, it is an even wager that out of 5642 other individuals also taken at the age of 30, and subjected to the same chances of mortality, the number who die before reaching the age of 50 will lie between 1245 ± 30, that is, between 1215 and 1275.

104. The following experiment recorded by Buffon, in his *Arithmetique Morale*, affords an example of the application of the preceding formulæ to the determination of the probable existence of a physical cause from the results of a large number of observations. A piece of money was tossed 4040 times successively, and the result was head 2048 times, and tail 1992 times. Supposing the piece to have been perfectly symmetrical, the most probable result would have been the same number of heads and tails. Let it now be proposed to assign the probability afforded by the experiment that the piece was not symmetrical, and that its form or physical structure was such as to render head an event, *a priori*, more probable than tail.

In this case $h = 4040$, $m = 2048$, $n = 1992$; and by (102) we have the probability R (or Θ, neglecting the correction) that p, the unknown chance of head, is comprised between the limits $\frac{m}{h} \pm \frac{\tau}{h}\sqrt{\frac{2mn}{h}}$. Now $\frac{m}{h} = \frac{2048}{4040} = .50693$, and $\frac{\tau}{h}\sqrt{\frac{2mn}{h}} = \tau \times .011124$, therefore if we assume $\tau \times .011124 = .00693$, we shall have the probability Θ that p is comprised between the limits $.50693 \pm .00693$, that is, between two limits of which the least is .5, or one-half. This assumption gives $\tau = .00693 \div .011124 = .623$; and the corresponding value of Θ is found from the table $= .62170$. Now if p lie between the above limits, its value is evidently greater than $\frac{1}{2}$; but the probability of its lying between those limits is not the whole probability that p is greater than $\frac{1}{2}$; for there is a chance of its exceeding the greatest limit, in which case also its value will be greater than $\frac{1}{2}$. The probability that p is *not* comprised between the assumed limits is $1 - .62170 = .37830$; and if it is not comprised between these limits, there is an equal chance of its being greater than the greatest limit, or less than the least; the probability of its exceeding the greatest limit is consequently $\frac{1}{2} \times .37830 = .18915$. Hence the whole probability that p is greater than .5, or that the chance of head is greater than that of tail is $.62170 + .18915 = .81085$; and the odds are therefore 81 to 19, or rather more than 4 to 1 that the piece was not perfectly symmetrical.

---

[1] This inference, though admitted by both Laplace and Poisson, is not strictly correct. In a paper published in the *Transactions of the Cambridge Philosophical Society*, (vol. vi. part iii.) Mr. De Morgan has shewn by a direct analysis that in the case of p and q not being known *a priori*, but made equal to the observed ratios $m \div h$, $n \div h$, the presumption of the true value of p lying within the limits stated in the text is not, as there inferred, $\Theta + \frac{1}{\sqrt{(2\pi hpq)}}\,e^{-\tau^2}$, but $\Theta - \frac{13p^2 - 13p + 1}{6hpq\sqrt{\pi}}\,e^{-\tau^2}$. The last correction to Θ is smaller than the former, and being divided by h, is of the order of quantities that have been rejected in the approximations. It is right to state that the method of simplifying the calculation of R in the direct case, by taking the integral Θ between limits corresponding to $l + \frac{1}{2}$ instead of l, is noticed, for the first time so far as we are aware, by Mr. De Morgan in the same paper.

105. The formulæ which have been demonstrated in the present section are immediately applicable to the determination of the probable limits of the gain or loss which may arise from undertaking a great number of risks with a given expectation in respect of each. The following question has important practical applications. A is interested in a great number of similar enterprises, in each of which E or F must necessarily happen. When E happens he receives the sum α, and when F happens he pays the sum β; required the probability that his gain or loss shall be comprised within given limits?

Let p be the chance of the event E, q that of F, and h the number of enterprises. Suppose E happens m times, and F n times; the sum to be received will be $m\alpha$, and the sum to be paid will be $n\beta$, and therefore his gain will be $m\alpha - n\beta$. Let $m = hp$, $n = hq$, then m times E and n times F is the most probable result, and in this case the gain $m\alpha - n\beta$ becomes $h(v\alpha - q\beta)$. Find τ from $l + \frac{1}{2} = \tau\sqrt{(2hpq)}$, then (98) Θ is the probability that the number of occurrences of E will lie between the limits $hp \mp l$. But if E happens $hp - l$ times, and consequently F $hq + l$ times, the corresponding benefit is $(hp - l)\alpha - (hq + l)\beta = h(p\alpha - q\beta) - l(\alpha + \beta)$; and if E happens $hp + l$ times, and F $hq - l$ times, the benefit is $(hp + l)\alpha - (hq - l)\beta = h(p\alpha - q\beta) + l(\alpha + \beta)$; whence Θ is the probability that his gain, that is, the difference between what he receives and what he pays, will be included within the limits $h(p\alpha - q\beta) \mp l(\alpha + \beta)$ both inclusive.

106. The following conclusions follow immediately from this solution.

(1). If $p\alpha$ be greater than $q\beta$, so that A has a mathematical advantage (however small) in each risk, the risk may be repeated a sufficient number of times, or h may be taken a sufficiently high number, to give a probability as nearly equal to certainty as we please, that A's gain shall exceed any given sum, however great.

(2). Let there be two players A and B, whose chances of gaining a game are respectively p and q, and let β be the sum staked upon each game by A, and α the sum staked by B, then $p\alpha$ is the mathematical expectation of A in respect of a single game, and $q\beta$ that of B; and if $p\alpha$ be greater than $q\beta$ (however small the difference) the game may be repeated so often as to give rise to a probability approaching as nearly to certainty as we please, that A's gain shall become equal to the whole of B's capital, and, consequently, that B will be ruined.

(3). If the mathematical expectations of the two players be equal, then $p\alpha - q\beta = 0$, and the most probable individual result of a large number of games, is that the gains and losses on either side shall be the same. But if l be supposed constant, then τ is inversely proportional to $\sqrt{h}$, and consequently the game may be repeated until Θ, the probability that the gain or loss $l(\alpha + \beta)$ shall be comprised within given limits, shall become as small as we please. Hence $1 - \Theta$, the probability that the gain or loss shall *not* be comprised within given limits, may be rendered as great as we please; and it follows that although the play may be on terms of perfect equality, it may be continued until a probability shall be obtained, approaching as nearly to certainty as we please, that one of the two players shall be ruined.

(4). The number of games which must be played, to afford a given amount of probability that one of the parties shall lose the whole of his fortune, depends on the magnitude of the stakes $(\alpha + \beta)$; but whether the stakes be large or small, the final result is the same. When the stakes are small, a greater number of games must be played.

107. As an example of this class of problems, we may take the following question: A and B engage in play with equal chances of winning, and stake five sovereigns on each game; how many games must they undertake to play in order that it may be two to one that one of them shall lose *at least* 100 sovereigns?

Here $p = \frac{1}{2}$, $q = \frac{1}{2}$, $\alpha = 5$, $\beta = 5$, and $l(\alpha + \beta) = 100$, whence $l = 10$. The equation $l + \frac{1}{2} = \tau\sqrt{(2hpq)}$ therefore becomes $10{\cdot}5 = \tau\sqrt{(h \div 2)}$, whence $h = 2 \times (10{\cdot}5)^2 \div \tau^2$. Now, the odds being 2 to 1 against the limits of the gain or loss not exceeding 100, the probability Θ of the limits not exceeding 100 is $\frac{1}{3} = {\cdot}33333$, corresponding to which the table gives by interpolation $\tau = {\cdot}30458$; substituting which in the above equation we find $h = 2376{\cdot}8$; so that if 2377 games are played, the odds are 2 to 1 that one of the players shall have gained at least 10 games more than half that number, and, consequently, that the other shall have gained at least 10 less than half, or that one of them shall have gained at least 20 games more than the other, and consequently have gained at least 100 sovereigns.

It is to be carefully observed that this question supposes the account between A and B not to be balanced until 2377 games have been played. If the condition of the play had been that it should cease as soon as A or B should have lost 100 sovereigns, the question would have been of an entirely different kind, and a much smaller number of games would have given the same probability of an equal loss.

108. The question just alluded to belongs to a class of problems connected with the *Duration of Play*, of extreme difficulty, and which have given rise to some of the most abstruse and refined researches in the modern analysis. In order to give an idea of the subject, we may take the following question, which has been frequently considered.

A and B, whose chances of winning a game are respectively p and q, play on these terms: A has m counters, and B has n counters; when A loses a game he gives a counter to B, and when B loses a game he gives a counter to A, and the play is to cease when one of them has lost all his counters. What is the probability that the play, which may go on for ever, shall be finished before more than h games shall have been played.

To take a simple case, suppose each to have three counters, and let the probability be required that the play shall be concluded with or before the ninth game. As the play cannot end with less than three games, let the binomial $(p + q)^3$ be developed, and the terms

$$p^3 + 3p^2q + 3pq^2 + q^3$$

give the respective probabilities of all the cases which can arise in three games. The first term is the probability of A gaining all the three games, the last term is the probability of B gaining them, and the sum of the remaining two terms is the probability that neither will win all the games, or the chance that a fourth will be played. Now, if the fourth game be played, p is A's chance of winning it, and q B's chance; but these chances will only exist in respect of the fourth game, provided the play be not concluded with the previous one, the probability of which is $3p^2q + 3pq^2$. Multiplying, therefore, $3p^2q + 3pq^2$ by $p + q$, the product

$$3p^3q + 6p^2q^2 + 3pq^3$$

gives the respective probabilities of the different ways in which the four games may be gained by A and B, excepting the two ways in which the play would have terminated with the third game. But the play cannot end in any of these ways; for, taking the first term for example, if B gains a counter before A gains three, the play cannot terminate until A gain back that counter, and three others besides, so that five games must be played. In fact, it is obvious that there is no way of gaining an odd number of counters in an even number of games, or *vice versa*. The last product therefore expresses the chance of the 5th game being played; and by reason of $p+q=1$ it is equal to $3p^2q+3pq^2$, the chance of the 4th being played, as it obviously ought to be, since the play cannot terminate with the 4th. Again, if the 5th game be played, p is A's chance of gaining it, and q B's chance of gaining it; multiplying therefore the last product by $p+q$, the different terms of the result, namely,

$$3p^4q+9p^3q^2+9p^2q^3+3pq^4$$

give the respective probabilities of all the cases which can arise by the 5th game. The first term is the probability of A gaining 4 games and B gaining 1, and the last term is the probability of B gaining 4 and A gaining 1. These terms therefore are the probabilities of the play ending in favour of A and B respectively with the 5th game, and the sum of the other two terms is the probability that the play will not terminate with the 5th game, or the chance of another game being played.

By pursuing the same reasoning it will be evident that on rejecting the two extreme terms of the above product, and multiplying the remainder by $p+q$, there will result the probabilities of the different ways in which six games may be played without the one player gaining all the counters of the other. But as the play cannot termimate with the 6th game, multiply again by $p+q$, and the result

$$9p^5q^2+27p^4q^3+27p^3q^4+9p^2q^5$$

will indicate the probability of the different cases that can arise out of the 7th game. Rejecting the two extreme terms, which give the respective probabilities of the play being concluded in favour of A or B, and multiplying the remaining two first by $p+q$ to obtain the different probabilities in respect of the 8th game, and again by $p+q$, as the play cannot terminate with the 8th, we have the product

$$27\,p^6q^3+81\,p^5q^4+81\,p^4q^5+27\,p^3q^6,$$

of which the first and last terms give the respective chances of A and B winning at the 9th game, and the sum of the other two terms the probability that the play will not be concluded by the 9th.

If we now collect the terms which have been set aside in the successive products, and denote by a and b the respective probabilities of A and B gaining at the 9th game, *or sooner*, we shall have

$$a=p^3+3\,p^4q+9\,p^5q^2+27\,p^6q^3,$$
$$b=q^3+3\,q^4p+9\,q^5p^2+27\,q^6p^3,$$

where the law of the series is evident.

It is easy to see that this process may be applied whatever be the number of counters which A and B have at the commencement, and whatever be the number, h, of games to which the play is limited. The general rule is as follows: of the two numbers m and n, let m be that which is not less than the other. Raise $p+q$ to the power n, and reject the first term (which gives the chance of A winning n games in succession), and also the last if $m=n$. Multiply the remainder $(h-n)$ times in succession by $(p+q)$, rejecting at each multiplication the first or last term of the product when it gives a combination which would terminate the play in favour of A or B; the sum of the terms rejected from the left-hand side of the different products gives the probability in favour of A, and the sum of the terms rejected from the right-hand side the probability in favour of B. As the coefficients of the successive products are obviously formed by adding the coefficient of the corresponding term in the preceding product to that of the term immediately before it, the products may be written down at once without the trouble of multiplication; but it is evident that when m, n, and h are large numbers, it would be quite impracticable to sum the series formed of the rejected terms by the ordinary methods. From the manner in which the series are derived, they are called *recurring* series; a general theory of which was first given by Demoivre in his *Doctrine of Chances*, and forms the most remarkable portion of that work.

109. The general problem is reduced to an equation of finite differences as follows: Let $y_{x,t}$ represent A's expectation when x games have been played, and he has still t counters to win, or B has t counters in his hand. If A gain the next game the value of his expectation will become $y_{x+1,t-1}$, and the chance of his gaining it is p; therefore his expectation in respect of that event is $py_{x+1,t-1}$. On the other hand, if A loses the next game his expectation will become $y_{x+1,t+1}$, and the chance of losing it is q; therefore his expectation in respect of that event is $qy_{x+1,t+1}$. Hence, according to the principles laid down in (32),

$$y_{x,t}=py_{x+1,t-1}+qy_{x+1,t+1}$$

a linear equation of finite differences, with three independent variables. It is therefore on the integration of an equation of this kind that the problem of the duration of play ultimately depends, but the subject is of much too complicated a nature to admit of its being satisfactorily explained in this place. We must therefore content ourselves with referring the reader to the treatise on generating functions, which forms the first part of the *Théorie Analytique* of Laplace.[1]

SECT. IX. OF THE MOST PROBABLE MEAN RESULTS OF NUMEROUS DISCORDANT OBSERVATIONS, AND THE LIMITS OF PROBABLE ERROR.

110. In the preceding section we have considered a class of questions which apply to events depending on constant causes, and supposed to be of such a nature that they necessarily happen or fail in each experiment, and have given formulæ by which approximate results can be obtained when the numbers involved are so large that they cannot be conveniently treated, or cannot be treated at all, by the ordinary methods of calculation. We come now to a more difficult problem, namely, to investigate the probable result of a large number of observations which have reference not to the simple occurrence or failure of a certain event, but to the magnitude of a thing, susceptible, within certain limits, of a very great or an infinite number of different values, equally or unequally probable, the chance of any particular value being also supposed to vary in each experiment. On account of its immediate application to the determination of the most probable values of astronomical and physical elements from the results of observation, this is, perhaps, in reference to practical utility, the most important question in the theory.

111. Let A represent a thing of any sort (as a line, or an angle, or a function of any quantity) which may have

---

[1] Lagrange, in vol. i. of the *Memoirs of the Society of Turin*, was the first who shewed that the investigation of the general term of a recurring series depends on the integration of a linear equation of finite differences. In vols. vi. and vii. of the *Memoires présentés à l'Academie des Sciences* of Paris, Laplace proposed a general method for the summation of recurring series by the integration of such equations, and in the latter volume gives a number of examples of their use in the more complicated questions in the theory of chances, amongst which is the problem enunciated in (108). The subject was afterwards resumed by Lagrange in the volume of the *Berlin Memoirs* for 1775, where he has given a more direct method than that of Laplace, for the integration of the class of equations in question, and also applied it to the solution of the principal problems proposed in the works of Montmort and Demoivre. A general solution of the problem in the text is given by Ampère in a Tract entitled *Considérations sur la Théorie Mathématique du Jeu*, (Lyons, 1802.)

every possible value within given limits, or which may be constant in itself, but of such a nature that its real magnitude can only be observed within certain limits of accuracy, and suppose a great number of observations to be made. The object is, in the first place, to assign the probability that the sum of the observed values shall fall within given limits, supposing the chances of the different values of A to be known *a priori;* and, in the second place, when the law of the chances is unknown, to determine from the observations themselves the most probable mean value of A, and also the limits within which there is a given amount of probability that the difference between such mean value, and the true but unknown value of A, shall be contained.

112. Let a and b be the limits of the possible values of A, x a value of A between a and b, and P the probability that the sum of the values of A given by h observations will be s exactly, s being a given quantity between ha and hb. Assume the values of A to be equidifferent, and multiples of a certain constant ϵ, and make

$$\alpha\epsilon=a,\ \beta\epsilon=b,\ \sigma\epsilon=s,\ i\epsilon=x,$$

where α, β, and σ are whole numbers (which may be positive or negative), and i is also a whole number proportional to x, and varying between the limits $i=\alpha$, and $i=\beta$, and which, therefore, may be positive or negative, or zero. If the different values of A are supposed to be equally probable, the chance of obtaining any given one of them, as x, in a single trial is unit divided by the number of possible values, or equal to $1\div(\beta-\alpha+1)$; and if we assume an indeterminate quantity w, then (20) the number of combinations which give the sum of h values of A equal to $\sigma\epsilon$ is the coefficient of that term of the multinomial

$$(w^{\alpha}+w^{\alpha+1}+w^{\alpha+2}\ldots\ldots+w^{\beta})^{h},$$

(or of the developement of $(\Sigma w^{i})^{h}$ from $i=\alpha$ to $i=\beta$) in which the exponent of w is σ; and consequently the probability P that the sum of the values of A will be s exactly is that coefficient divided by $(\beta-\alpha+1)^{h}$.

113. If the chances of the different values of A are unequal, and also vary in each trial, let p_1 be the probability of the observed value of A being x in the first trial, p_2 the probability of its being x in the second, p_3 that of its being x in the third, and so on. Now when $h=1$, or when there is only a single trial, then $s=x=i\epsilon$, and we have $P=p^{1}$. If $h=2$, then, assuming $i\epsilon$ to be the value of A in the first trial, and $i'\epsilon$ its value in the second, (i and i' being any two numbers between α and β), the two observations may give the sum of the two values equal to $\sigma\epsilon$ in as many different ways as it is possible to satisfy the equation $i+i'=\sigma$; and consequently, according to the theory of combinations, P is the coefficient of that term of the product (arranged according to the powers of w) of the two series represented by $\Sigma p_1 w^{i\epsilon}$ and $\Sigma p_2 w^{i\epsilon}$, in which the exponent of w is equal to $\sigma\epsilon$. In like manner, if $h=3$, then the sum of the observed values of A may be equal to $\sigma\epsilon$ in as many different ways as the equation $i+i'+i''=\sigma$ admits of different solutions, and consequently P is the coefficient of the term of the developement of the product $\Sigma p_1 w^{i\epsilon}\,.\,\Sigma p_2 w^{i\epsilon}\,.\,\Sigma p_3 w^{i\epsilon}$, in which the exponent of w is equal to $\sigma\epsilon$. Generally, when the number of observations is h, the probability P of the sum of the observed values of A being s, or $\sigma\epsilon$, exactly, is the coefficient of $w^{\sigma\epsilon}$ in the developement of the product

$$\Sigma p_1 w^{i\epsilon}\,.\,\Sigma p_2 w^{i\epsilon}\,.\,\Sigma p_3 w^{i\epsilon}\ldots\ldots\ldots\ldots\Sigma p_h w^{i\epsilon},$$

the sums Σ including all values of i from $i=\alpha$ to $i=\beta$.

Assume $w^{\epsilon}=e^{\theta\sqrt{-1}}$ (e being the base of the Napierean logarithms), and let the above product be denoted by X. We shall then have

$$X=\Sigma p_1 e^{i\theta\sqrt{-1}}\,.\,\Sigma p_2 e^{i\theta\sqrt{-1}}\,.\,\Sigma p_3 e^{i\theta\sqrt{-1}}\ldots\ldots\Sigma p_h e^{i\theta\sqrt{-1}}.$$

Now since P is the coefficient of the term of the developement of this product which contains the factor $e^{\sigma\theta\sqrt{-1}}$, if we conceive the developement effected we shall have

$$X=Pe^{\sigma\theta\sqrt{-1}}+P'e^{\sigma'\theta\sqrt{-1}}+\&c.$$

a series in which all the terms are of the same form. Multiplying both sides of the equation by $e^{-\sigma\theta\sqrt{-1}}$, we get

$$Xe^{-\sigma\theta\sqrt{-1}}=P+P'e^{(\sigma'-\sigma)\theta\sqrt{-1}}+\&c.$$

Now by a well known theorem in trigonometry, (ALGEBRA, art. 269), $e^{(\sigma'-\sigma)\theta\sqrt{-1}}=\cos(\sigma'-\sigma)\theta+\sqrt{-1}\sin(\sigma'-\sigma)\theta$; substituting therefore this value, and multiplying by $d\theta$, the equation becomes

$$Xe^{-\sigma\theta\sqrt{-1}}d\theta=Pd\theta+P'\{\cos(\sigma'-\sigma)\theta+\sqrt{-1}\sin(\sigma'-\sigma)\theta\}d\theta+\&c.$$

The factor which multiplies P′ in this equation will evidently become zero when integrated from $\theta=-\pi$ to $\theta=+\pi$, (π being the semicircumference to radius 1), the positive and negative elements of the integral being equal, and consequently destroying each other. The same thing also takes place with respect to the following terms, which are all of the same form. Integrating therefore between those limits, and observing that $\int d\theta=2\pi$, we find

$$P=\frac{1}{2\pi}\int_{-\pi}^{+\pi}Xe^{-\sigma\theta\sqrt{-1}}d\theta.$$

114. This value of P denotes the infinitely small chance that the sum of the values of A in h trials will be s exactly. Let μ and ν be two integer numbers between $h\alpha$ and $h\beta$, and let Q denote the probability that s will be comprised between the two limits $\mu\epsilon$ and $\nu\epsilon$, (these limits being included between ha and hb); then Q will be found by substituting successively μ, $\mu+1$, $\mu+2,\ldots\nu$ for σ in the above value of P, and taking the sum of all the resulting terms. This substitution gives the following series multiplied by X under the sign of integration:

$$e^{-\mu\theta\sqrt{-1}}+e^{-(\mu+1)\theta\sqrt{-1}}+e^{-(\mu+2)\theta\sqrt{-1}}\ldots+e^{-\nu\theta\sqrt{-1}}$$

On multiplying the series now found by $e^{\frac{1}{2}\theta\sqrt{-1}}-e^{-\frac{1}{2}\theta\sqrt{-1}}$ $(=2\sqrt{-1}\sin\frac{1}{2}\theta)$, all the terms of the product, excepting the first and the last, destroy each other, and the sum of the terms becomes simply

$$e^{-(\mu-\frac{1}{2})\theta\sqrt{-1}}-e^{(\nu+\frac{1}{2})\theta\sqrt{-1}};$$

therefore on making the substitution, and performing the multiplication now indicated, and dividing by $2\sqrt{-1}\sin\frac{1}{2}\theta$, we obtain for the value of Q the equation Q=

$$\frac{1}{4\pi\sqrt{-1}}\int_{-\pi}^{+\pi}X\left\{e^{-(\mu-\frac{1}{2})\theta\sqrt{-1}}-e^{-(\nu+\frac{1}{2})\sqrt{-1}}\right\}\frac{d\theta}{\sin\frac{1}{2}\theta}.$$

115. In order to simplify the expression for Q, let the number of possible values of A within the given limits be conceived to be infinite, in which case the constant ϵ becomes infinitely small, and therefore, since the limits are finite, μ and ν infinitely great. Let the following substitutions also be made:

$$\mu\epsilon=\psi-\delta,\ \nu\epsilon=\psi+\delta,\ \theta=\epsilon z,$$

δ being positive in order that ν may be greater than μ, agreeably to what has already been assumed. On substituting these expressions in the above equation, the limits of the new variable z will be ± infinity; for ϵ having been supposed infinitely small, z must become infinitely great when $\theta=\pi$. Now since μ and ν are infinitely great, $\mu-\frac{1}{2}$ and $\nu+\frac{1}{2}$ become sensibly μ and ν, whence we have

$e^{-(\mu-\frac{1}{2})\theta\sqrt{-1}}-e^{-(\nu+\frac{1}{2})\theta\sqrt{-1}}=e^{-\psi z}\,(e^{\delta z\sqrt{-1}}-e^{-\delta z\sqrt{-1}})$ $=e^{-\psi z}2\sqrt{-1}\sin\delta z$. Again, by reason of $\theta=\epsilon z$, we have $d\theta=\epsilon dz$; and ϵ being infinitely small, θ must be a very small arc, therefore $\frac{1}{2}\theta$ may be taken for $\sin\frac{1}{2}\theta$, whence $d\theta\div\sin\frac{1}{2}\theta=2dz\div z$. By means of these transformations the expression for Q becomes

$$Q=\frac{1}{\pi}\int_{-\infty}^{+\infty}Xe^{-\psi z\sqrt{-1}}\sin\delta z\,.\frac{dz}{z},$$

and denotes the probability that the sum of the h values of A will lie between $\psi\mp\delta$.

116. It is now necessary to assign a value to the product denoted by X. Since the number of possible values of A between a and b has been supposed infinite, the chance of obtaining any given one of them, as x, in a single trial, is infinitely small. Assuming this chance to be a function of x, and to vary in the different trials, let it be represented by $\phi_n x$ in respect of the nth trial. In order to preserve continuity in the values of A, this must be understood as signifying that $\phi_n x dx$ is the infinitely small chance that the value of A given by the nth observation will lie between x and $x+dx$. The function $\phi_n x$, therefore, represents the *law of the facility* of the different values of A. It is positive for all values of x between a and b, and vanishes for all values of x less than a or greater than b; and it is important to remark, that whatever number n may be, the integral $\int\phi_n x dx$ taken from $x=a$ to $x=b$ is always equal to unity; for since every observation gives a value of A between a and b, the sum of all the probabilities in respect of each observation must be unity or certainty. From this assumption, then, we have $\phi_1 x dx=p_1$, $\phi_2 x dx=p_2$...... $\phi_h x dx=p_h$, whence the sums $\Sigma p_n e^{i\theta\sqrt{-1}}$ (113) are changed into definite integrals; and therefore, since $\theta=\epsilon z$, $x=i\epsilon$, and consequently $i\theta=xz$, we obtain for the value of X,

$$X=\int e^{zx\sqrt{-1}}\phi_1 x dx\,.\int e^{zx\sqrt{-1}}\phi_2 x dx\ldots\int e^{zx\sqrt{-1}}\phi_h x dx,$$

the limits of the integrals being $x=a$ and $x=b$.

By reason of $e^{zx\sqrt{-1}}=\cos zx+\sqrt{-1}\sin zx$, each of these integrals may be expressed in terms of the cosine and sine of zx. The nth, for instance, becomes $\int\phi_n x\cos zx.dx$ $+\sqrt{-1}\int\phi_n x\sin zx.dx$. Now since $\int\phi_n dx=1$, (from $x=a$ to $x=b$), and $\phi_n x$ can have only positive values, each of the integrals is less than 1; whence we may assume

$$\int\varphi_n x\cos zx.dx=R_n\cos r_n;\ \int\varphi_n x\sin zx.dx=R_n\sin r_n;$$

R_n being a positive quantity, and r_n an angle having always a real value. This gives

$$\int e^{zx\sqrt{-1}}\phi_n x dx=R_n(\cos r_n-\sqrt{-1}\sin r_n)=R_n e^{r_n\sqrt{-1}};$$

whence substituting successively for n the numbers 1, 2, 3...h, and for the sake of brevity making

$$Y=R_1\times R_2\times R_3\ldots\ldots\ldots\times R_h,$$
$$y=r_1+r_2+r_3\ldots\ldots\ldots\ldots+r_h,$$

we get $X=Ye^{y\sqrt{-1}}$; and the expression for Q becomes

$$Q=\frac{1}{\pi}\int_{-\infty}^{+\infty}Ye^{(y-\psi z)\sqrt{-1}}\sin\delta z\,.\frac{dz}{z}.$$

117. The integral in this last expression is equivalent to two others, namely

$$\int Y\cos(y-\psi z)\sin\delta z.\frac{dz}{z}+\sqrt{-1}\int Y\sin(y-\psi z)\sin\delta z.\frac{dz}{z}.$$

Now, on attending to the nature of the quantities represented by Y and y, it will be manifest that according as z is positive or negative, r_n, and consequently y is positive or negative, while Y is positive in all cases, since R_n is always positive. Hence $\cos(y-\psi z)$ is always positive, and the elements of the first of the above integrals having thus the same value and the same sign for the same value of z, whether z be positive or negative, the value of the integral from $-\infty$ to $+\infty$ is the double of its value from 0 to ∞. On the other hand, since y and z have both the same sign, $\sin(y-\psi z)$ is positive or negative according as z is positive or negative, and the elements of the integral into which it enters being equal for $-z$ and $+z$, but having contrary signs, destroy each other, and the integral from $x=-\infty$ to $x=+\infty$ vanishes. The expression for Q is therefore transformed into

$$Q=\frac{2}{\pi}\int_0^{\infty}Y\cos(y-\psi z)\sin\delta z.\frac{dz}{z}.$$

118. The formula now found cannot in general be integrated by any of the known methods, but in the present case the quantities denoted by Y and y are such that an approximate value of Q may be obtained, which will always be more nearly equal to the true value as h, the number of observations, is increased. On adding the squares of the two quantities represented by $R_n\cos r_n$ and $R_n\sin r_n$ we get

$$R_n^2=(\int\phi_n x\cos zx.dx)^2+(\int\phi_n x\sin zx.dx)^2.$$

If $z=0$, this becomes $R_n=\int\phi_n x dx$, whence by (116), $R_n=1$. When z has a real value, then it may be shewn that R_n is less than 1; for let x' be any value of A different from x, then as x' can only vary from as a to b, we have obviously,

$$\int\varphi_n x'\cos zx'.dx'=\int\varphi_n x\cos zx.dx,\ \text{and}\ \int\varphi_n x'\sin zx'.dx'=\int\phi_n x\sin zx.dx,$$

and the above equation may be put under this form,

$$R^2{}_n=\int\varphi_n x\cos zx.dx\cdot\int\varphi_n x'\cos zx'dx'+\int\varphi_n x\sin zx.dx\cdot\int\varphi_n x'\sin zx'dx,$$

whence

$$R^2{}_n=\iint\phi_n x\phi_n x'\cos z(x-x')dxdx'.$$

Now, excepting the case in which $z=0$, this double integral is always less than $\iint\phi_n x\phi_n x'dxdx'$, or less than $(\int\phi_n x dx)^2$, and consequently R_n is less than $\int\phi_n x dx$, that is, less than unity. Since, then, it has been shewn that R_n is equal to unity when $z=0$, and less than unity for all other values of z, and since Y is a quantity of the order R_n^h, it follows that Y must diminish with great rapidity when z, or its equal $\theta\div\epsilon$ differs sensibly from 0, and even for very small values of z becomes insensible when h is a large number. We may therefore assume $Y=e^{-\theta^2}$, an expression which is equal to unity when $\theta=0$, and diminishes rapidly as θ is increased, and becomes zero when θ is infinite.

119. For the sake of abridging let us assume

$$k_n=\int x\phi_n x dx,\ k'_n=\int x^2\phi_n x dx,\ k''=\int x^3\phi_n x dx,\ \&c.$$

(the integrals in respect of x being always from $x=a$ to $x=b$). From known formulæ we have

$$\cos zx=1-\frac{z^2x^2}{2}+\frac{z^4x^4}{2.3.4}-\&c.;\ \sin zx=zx-\frac{z^3x^3}{2.3}+\&c.;$$

substituting these series for $\cos zx$ and $\sin zx$ in the integrals $\int\phi_n x\cos zx.dx$ and $\int\phi_n x\sin zx.dx$, and also k_n, k'_n, k''_n, &c., for the values they have now been assumed to represent, then, from (116) we have

$$R_n\cos r_n=1-\frac{z^2}{2}k'_n+\frac{z^4}{2.4}k'''_n-\&c.$$

$$R_n\sin r_n=zk_n-\frac{z^3}{2.3}k''_n+\&c.$$

and it will be seen presently that all the terms involving higher powers of z than the cube may be neglected. Adding together the squares of these two equations, we get $R_n^2=1-z^2(k'_n-k^2{}_n)+z^4f-\&c.$; whence

$$R_n=1-\tfrac{1}{2}z^2(k'_n-k^2{}_n)+z^4f'-\&c.;$$

f' being independent of z. On dividing the second by the first, there results $\tan r_n = zk_n - \frac{1}{6}z^3k''_n + \frac{1}{2}z^3k_nk'_n - \&c.$; whence by reason of $r_n = \tan r_n - \frac{1}{3}\tan^3 r_n + \&c.$,

$$r_n = zk_n - \tfrac{1}{6}z^3\,(k''_n - 3k_nk'_n + 2k_n^3) + \&c.$$

If, therefore, we make

$$c_n = \tfrac{1}{2}(k'_n - k^2_n),\quad g_n = \tfrac{1}{6}z^3(k''_n - 3k_nk'_n + 2k_n^3),$$

the values of R_n and r_n become respectively

$$R_n = 1 - z^2c_n + z^4f' - \&c.;\quad r_n = zk_n - z^3g_n + \&c.$$

Now, by hypothesis (116) $Y = R_1 \times R_2 \times R_3 \ldots\ldots R_h$; therefore $\log Y = \Sigma \log R_n = \Sigma \log(1 - z^2c_n + z^4f' - \&c.) = -\Sigma\{z^2c_n - z^4(f' - \frac{1}{2}c_n) - \&c.\}$ (by reason of the formula $\log R_n = R_n - 1 - \frac{1}{2}(R_n - 1)^2 + \&c.$) But we have also assumed (117) $Y = e^{-\theta^2}$; hence $\log Y = -\theta^2$, and consequently $\theta^2 = \Sigma\{z^2c_n - z^4(f' - \frac{1}{2}c_n) - \&c.\}$ In like manner, since $y = r_1 + r_2 + r_3 \cdots + r_h = \Sigma r_n$, therefore $y = \Sigma zk_n - \Sigma z^3g_n + \&c.$ Now, the sums Σ include all values of c_n, k_n, g_n, from $n = 1$ to $n = h$; let the mean values of those quantities, therefore, be denoted by c, k, g, that is to say, let

$$\Sigma c_n = hc,\ \Sigma k_n = hk,\ \Sigma g_n = hg,$$

and make also $hf'' = \Sigma(f' - \frac{1}{2}c_n)$, and we have $\theta^2 = z^2hc - z^4hf'' + \&c.$ By reverting the series the value of z is found in terms of θ; namely $z = \dfrac{\theta}{\sqrt{(hc)}} + \dfrac{f''\theta^3}{2hc^2\sqrt{(hc)}} + \&c.$

But the second term of this series, being divided by $h\sqrt{h}$, and h being by supposition a large number, is very small in comparison of the first, and may be neglected as insensible. All the succeeding terms of the series are divided by higher powers of h, and may therefore be rejected *a fortiori*. Confining the approximation, therefore, to terms of the order $1 \div \sqrt{h}$, and rejecting all those into which h or its powers enters as a divisor, we have $z = \theta \div \sqrt{(hc)}$, and likewise $dz \div z = d\theta \div \theta$.

From (116) we have also $y = \Sigma r_n = z\Sigma k_n - z^3\Sigma g_n + \&c.$, therefore in consequence of the above transformations, $y = zhk - z^3hg + \&c.$; and on substituting for z its value just found in terms of θ, $y = k\theta\sqrt{(h \div c)} - g\theta^3 \div c\sqrt{(hc)}$, and consequently $y - \psi z = (hk - \psi)\theta \div \sqrt{(hc)} - g\theta^3 \div c\sqrt{(hc)}$. In order to deduce from this an expression for $\cos(y - \psi z)$, let u and v denote any two arcs, then by trigonometry, $\cos(u - v) = \cos u \cos v + \sin u \sin v$. Suppose v to be small, and let its cosine and sine be developed in series and substituted in this equation; it will become

$$\cos(u - v) = \cos u - \frac{v^2}{1.2}\cos u + \&c. + v\sin u - \frac{v^3}{2.3}\sin u + \&c.$$

whence, making $u = (hk - \psi)\theta \div \sqrt{(hc)}$, $v = g\theta^3 \div c\sqrt{(hc)}$, and rejecting as before terms of the order $1 \div h$, we have

$$\cos(y - \psi z) = \cos\left\{(hk - \psi)\frac{\theta}{\sqrt{(hc)}}\right\} + \frac{g\theta^3}{c\sqrt{(hc)}}\sin\left\{(hk - \psi)\frac{\theta}{\sqrt{(hc)}}\right\}.$$

If we now substitute the values of Y, z, dz, $\cos(y - \psi z)$ found in the last three paragraphs in the value of Q (117) we obtain the following expression in which the largest terms omitted are of the order $1 \div h$, and which therefore is more accurate as h is a higher number, viz.

$$Q = \frac{2}{\pi}\int_0^\infty e^{-\theta^2}\cos\left\{(hk - \psi)\frac{\theta}{\sqrt{(hc)}}\right\}\sin\frac{\delta\theta}{\sqrt{(hc)}}.\frac{d\theta}{\theta}$$
$$+ \frac{2g}{\pi c\sqrt{(hc)}}\int_0^\infty e^{-\theta^2}\sin\left\{(hk - \psi)\frac{\theta}{\sqrt{(hc)}}\right\}\sin\frac{\delta\theta}{\sqrt{(hc)}}.\theta^2 d\theta.$$

120. As no restriction has yet been made with respect to the value of ψ, excepting that it is a mean between $\mu\epsilon$ and $\nu\epsilon$, and therefore included between ha and hb (115), let us now assume $\psi = hk$. This gives $\cos(hk - \psi) = 1$, and $\sin(hk - \psi) = 0$; and the equation becomes

$$Q = \frac{2}{\pi}\int_0^\infty e^{-\theta^2}\sin\frac{\delta\theta}{\sqrt{(hc)}}.\frac{d\theta}{\theta},$$

which is the probability that the sum of the observed values of A will fall between $hk \mp \delta$.

121. The last step in this investigation is to reduce the integral now found to a known form, which may be accomplished as follows: Let u be a new variable, then by means of the trigonometrical formula $\cos u = \frac{1}{2}e^{u\sqrt{-1}} + \frac{1}{2}e^{-u\sqrt{-1}}$,

$$\int e^{-\theta^2}\cos u\theta.d\theta = \tfrac{1}{2}\int e^{-\theta^2 + u\theta\sqrt{-1}}d\theta + \tfrac{1}{2}\int e^{-\theta^2 - u\theta\sqrt{-1}}d\theta.$$

But $-\theta^2 + u\theta\sqrt{-1} = -\frac{1}{4}u^2 - (\theta - \frac{1}{2}u\sqrt{-1})^2$; assume therefore, $v = \theta - \frac{1}{2}u\sqrt{-1}$ (whence $dv = d\theta$), then

$$\tfrac{1}{2}\int e^{-\theta^2 + u\theta\sqrt{-1}}d\theta = \tfrac{1}{2}\int e^{-\frac{1}{4}u^2 - v^2}dv = \tfrac{1}{2}e^{-\frac{1}{4}u^2}\int e^{-v^2}dv.$$

When $\theta = 0$, then $v = -\frac{1}{2}u\sqrt{-1}$, and when θ is infinite, v is infinite; therefore, if the integral in respect of θ be taken from $\theta = 0$ to $\theta = \infty$, the integral in respect of v must be taken from $v = -\frac{1}{2}u\sqrt{-1}$ to $v = \infty$.

If we now suppose u to be negative, we shall have in like manner $\frac{1}{2}\int e^{-\theta^2 - u\theta\sqrt{-1}}d\theta = \frac{1}{2}e^{-\frac{1}{4}u^2}\int e^{-v^2}dv$, the limits in this case being from $v = +\frac{1}{2}u\sqrt{-1}$ to $v = \infty$. Hence

$$\int e^{-\theta^2}\cos u\theta.d\theta = \tfrac{1}{2}e^{-\frac{1}{4}u^2}\left(\int c^{-v^2}dv + \int e^{-\ ^2}dv\right).$$

But the sum of the two integrals on the right-hand side of this equation, the first being taken from $v = -\frac{1}{2}u\sqrt{-1}$ to infinity, and the second from $v = +\frac{1}{2}u\sqrt{-1}$ to infinity, is obviously the double of $\int e^{-v^2}dv$ from $v = 0$ to $v = \infty$, or (96) equal to $\sqrt{\pi}$; and we have therefore

$$\int_0^\infty e^{-\theta^2}\cos u\theta.d\theta = \tfrac{1}{2}\sqrt{\pi}.e^{-\frac{1}{4}u^2}.$$

Let both sides of the equation be multiplied by du, and integrated from $u = 0$ to $u = \delta \div \sqrt{(hc)} = u'$; then observing that $\int\cos(u\theta)d\theta = \sin(u\theta) \div \theta$, we shall have

$$\int_0^\infty e^{-\theta^2}\sin\frac{\delta\theta}{\sqrt{(hc)}}.\ \frac{d\theta}{\theta} = \tfrac{1}{2}\sqrt{\pi}\int_0^{u'} e^{-\frac{1}{4}u^2}du.$$

Comparing this equation with that in (110), we find $Q = (1 \div \sqrt{\pi})\int_0^{u'} e^{-\frac{1}{4}u^2}du$. Now, let $u = 2t$, and let τ be what t becomes when $u = u' = \delta \div \sqrt{(hc)}$; then $\frac{1}{4}u^2 = t^2$, $du = 2dt$, $\delta \div \sqrt{(hc)} = 2\tau$, or $\delta = 2\tau\sqrt{(hc)}$, and we have, finally,

$$Q = \frac{2}{\sqrt{\pi}}\int_0^\tau e^{-t^2}dt,\ \text{or,}\ Q = 1 - \frac{2}{\sqrt{\pi}}\int_\tau^\infty e^{-t^2}dt,$$

for the probability that s, the sum of the observed values of A, will be comprised between the limits $\psi - \delta$ and $\psi + \delta$, that is, between $hk \mp 2\tau\sqrt{(hc)}$; or, that the arithmetical mean of all the observations, namely $s \div h$, will lie between $k \mp 2\tau\sqrt{(c \div h)}$.

122. The expression now found for Q is that which in (96) was denoted by Θ, and of which the table gives the values corresponding to the different values of τ. The general result of the investigation is, therefore, that whatever be the nature of the function $\phi_n x$ which represents the law of the facility of the different values of A, if a large number of observations be made, the sum of the values of A, divided by the number of observations, approaches continually to a certain special quantity k (which is the true mean value of A) as the number of observations is increased, and that by multiplying the number of observations, a probability Θ may always be obtained, approaching as nearly to certainty as we please, that the difference between the arith-

metical mean or average of the observations and the true mean value of A, will be comprised within limits which may be made as small as we please.

The analysis employed in the preceding articles, (113 to 121), for the purpose of establishing this very important result, belongs to Poisson, and is given in nearly the same form in the *Recherches sur la Probabilité des Jugements*, chap. iv., and in the *Additions* to the *Connaissance des Tems* for 1832. We have preferred it to the method followed by Laplace in the *Théorie Analytique*, as being somewhat simpler and also more general.

123. In order that the limits $2\tau\sqrt{(hc)}$ may be real, it is necessary that the special quantity c be positive, a condition which has hitherto been assumed. Now, since $c=\Sigma c_n \div h$, it is obvious that c will be positive if $c_n=\frac{1}{2}(k'_n-k^2_n)$ be positive. On writing for k'_n and k_n their values (119) we have

$$2c_n=\int x^2\phi_n x dx-(\int x\phi_n x dx)^2,$$

the limits of the integrals being always from $x=a$ to $x=b$. But it is evident that no change will be made in the values of these definite integrals (the limits continuing the same), by substituting in them any other of the possible values of A, as x'. We have therefore $\int x'\varphi_n x' dx'=\int x\phi_n x dx$, and since in all cases $\int\phi_n x' dx'=1$, the above equation may be otherwise written

$$2c_n=\int x^2\phi_n x dx \int\varphi_n x' dx'-\int x\varphi_n x dx \int x'\varphi_n x' dx,$$

whence $2c_n=\iint\varphi_n x\varphi_n x'(x^2-xx')dxdx'$,

or $\quad 2c_n=\iint\varphi_n x\phi_n x'(x'^2-x'x)dxdx'$.

Adding together the two last equations, there results

$$4c_n=\iint\varphi_n x\phi_n x'(x-x')^2 dxdx',$$

a quantity which is necessarily positive, and can never be zero so long as x can have different values.

124. The special quantity k to which the average of the values of A continually approaches, is connected with the centre of gravity of the area of a curve by the following relation. Let x and y be the co-ordinates of a curve, of which the equation is $y=\phi_n x$; then the element of the area is $\phi_n x dx$. But (116) $\varphi_n x dx$ is the infinitely small probability that the value of A in the nth observation will lie between x and $x+dx$; therefore the element of the area of the curve represents this probability, and the curve itself represents the law of the probability of the different values of A in respect of the nth trial. In like manner, the curve whose coordinates are x and $(1\div h)\Sigma\varphi_n x$, represents the law of the mean probability of A in respect of the whole series of observations. Now, if x_1 be the abscissa of the centre of gravity of any curve whose co-ordinates are x and y, the well known formula of mechanics gives $x_1=\int yxdx \div \int ydx$; therefore, applying this formula to the curve of the mean probability, and making the whole area ($\int ydx$ from $x=a$ to $x=b$)$=1$, the absciss of the centre of gravity is $x_1=(1\div h)\Sigma\int x\varphi_n x dx$. But this is the quantity denoted by k (119); hence the special quantity to which the average of a large number of observations indefinitely approaches is the abscissa of the centre of gravity of the area of the curve which represents the law of the mean chances of A.

125. It has been assumed in the foregoing analysis that A is susceptible of an infinite number of values, increasing continuously from a to b. The results, however, are easily adapted to those cases in which the number of possible values of A is finite. Suppose A to be a thing susceptible of only λ different values, represented by $a_1, a_2, a_3 \ldots\ldots a_\lambda$, and let the chances of these values, which may be different in the different trials, be respectively $\gamma_1, \gamma_2, \gamma_3 \ldots\ldots \gamma_\lambda$ in respect of the nth trial. Now, suppose $\varphi_n x$ to be a discontinuous function, which vanishes for all values of x, of which the difference from one or other of the above values of A exceeds an infinitely small quantity ϵ; then the whole integral $\int\varphi_n x dx$ from $x=a$ to $x=b$, will be made up of a series of λ partial integrals $\int\varphi_n x dx$ taken between the limits $a_i \pm \epsilon$, the sum of which will be unity, since one or other of the values of A must necessarily be given by the trial. But the integral $\int\varphi_n x dx$ between the limits $a_i \pm \epsilon$ is the expression of the chance that the value of A given in the nth trial will lie between $a_i \pm \epsilon$; whence for those limits $\int\varphi_n x dx=\gamma_i$. Now the difference $x-a_i$ must be infinitely small, since it cannot exceed ϵ; we may therefore substitute a_i for x, and a_i^2 for x^2 under the sign of integration, when the limits are $a_i \pm \epsilon$, so that for those limits we have $\int x\varphi_n x dx=a_i\int\varphi_n x dx=\gamma_i a_i$. On writing for i all the different numbers 1, 2, 3……λ, and observing that the λ partial integrals thus formed make up the whole integral $\int x\varphi_n x dx$ from $x=a$ to $x=b$, and that therefore their sum is k_n, we have, in respect of the nth trial,

$$k_n=\gamma_1 a_1+\gamma_2 a_2+\gamma_3 a_3\ldots\ldots+\gamma_\lambda a_\lambda.$$

In like manner, for $k'_n=\int x^2\varphi_n x dx$ (from a to b), we have

$$k'_n=\gamma_1 a_1^2+\gamma_2 a_2^2+\gamma_3 a_3^2\ldots\ldots+\gamma_\lambda a_\lambda^2;$$

so that the two special quantities k and k' become

$$k=(1\div h)\Sigma(\gamma_1 a_1+\gamma_2 a_2+\gamma_3 a_3\ldots\ldots+\gamma_\lambda a_\lambda),$$

$$k'=(1\div h)\Sigma(\gamma_1 a_1^2+\gamma_2 a_2^2+\gamma_3 a_3^2\ldots\ldots+\gamma_\lambda a_\lambda^2),$$

the sums Σ extending to all the h values of n, or to all the trials, the chances denoted by γ_1, γ_2, &c. being supposed to vary in the different trials.

126. When the chances of the different values of A are equal and constant, then $\gamma_i=1\div\lambda$, and the above values of k and k' become

$$k=(1\div\lambda)(a_1+a_2+a_3\ldots\ldots+a_\lambda),$$

$$k'=(1\div\lambda)(a_1^2+a_2^2+a_3^2\ldots\ldots+a_\lambda^2),$$

so that k is the arithmetical mean of the possible values of A, and k' the mean of the squares of those values. On this hypothesis, therefore, k and k' may be computed *a priori*, and consequently the limits determined within which there is a given probability Θ that the average of h observations will fall, the limits being $k\mp 2\tau\sqrt{(c\div h)}$, where $c=\frac{1}{2}(k'-k^2)$.

When the chances of the different values of A are unequal, but constant in the different trials, then $k=k_n$, and $k'=k'_n$, and we have

$$k=\gamma_1 a_1+\gamma_2 a_2+\gamma_3 a_3\ldots\ldots+\gamma_\lambda a_\lambda,$$

$$k'=\gamma_1 a_1^2+\gamma_2 a_2^2+\gamma_3 a_3^2\ldots\ldots+\gamma_\lambda a_\lambda^2.$$

In this case the special quantity k to which the average of the observed values continually approaches, is the sum of the possible values, each multiplied into its respective probability; and k' is the sum of the products of the squares of those values into their respective probabilities.

127. Resuming the consideration of the general formula in (121), we shall now give an example of its application when the function which represents the law of facility of the different values of A is supposed to be known *a priori.*

Of all the hypotheses which may be made respecting the law of facility, the simplest is that which supposes the chances of all the possible values of the thing observed to be equal, and to remain constant during the series of trials. This supposes $\varphi_n x=\varphi x=$a constant; whence $\int\varphi x dx$, between the limits $x=a$ and $x=b$, becomes $(b-a)\varphi x$. But between those limits we have also $\int\varphi x dx=1$; therefore $\varphi x=1\div(b-a)$. From this value of φx it is easy to deduce the special quantities k and k'. On the present hypothesis $k=k_n$ and $k'=k'_n$; therefore, the limits of the integral being $x=a$ and $x=b$, we have $k=\int x\varphi x dx=\int\frac{xdx}{b-a}=\frac{b^2-a^2}{2(b-a)}=\frac{1}{2}(b+a)$, whence $k^2=\frac{1}{4}(b+a)^2$. In like manner $k'=\int x^2\varphi x dx$ becomes $\int\frac{x^2dx}{b-a}=\frac{1}{3}(b^2+ba+a^2)$; whence $c=\frac{1}{2}(k'-k^2)$

$=\frac{1}{6}(b^2+ba+a^2)-\frac{1}{8}(b+a)^2$. Hence by (121) we have the probability Θ that the average value of A given by h observations, or the sum of the values of A divided by their number, will lie between

$$\tfrac{1}{2}(b+a)\mp 2\tau\surd\{\tfrac{1}{6}(b^2+ba+a^2)-\tfrac{1}{8}(b+a)^2\}\div\surd h.$$

128. This formula may be applied to the following question. Of the comets which have been observed since the year 240 of our era, the parabolic elements of 138 have been computed, and the mean inclination of their orbits to the ecliptic is found to be 48° 55′. Now, supposing every possible inclination of an orbit to be equally probable, let the probability be demanded that the mean inclination of 138 orbits will not differ from 45° (the mean of the possible inclinations) more than 5° in excess or defect.

In this case the limits of the possible values of the phenomenon are 0 and 90°. We have therefore $a=0$, $b=90°$, $h=138$, and the above limits of the error of the average, become $45°\mp\tau\times 90°\div\surd(6\times 138)$. In order that the limits may not exceed 5°, we have to determine τ from the equation $\tau\times 90°\div\surd(6\times 138)=5°$, which gives $\tau=\frac{1}{3}\surd 23$; whence $\tau=1{\cdot}6$ very nearly. The tabular value of Θ corresponding to $\tau=1{\cdot}6$ is ·97635, or nearly $\frac{41}{42}$; and the odds are therefore 41 to 1 that on the supposition of all inclinations being equally probable, the mean inclination of 138 comets would fall between $45°\mp 5°$, that is, between 40° and 50°. The mean of the inclinations actually computed falls within those limits (being 48° 45′); there is therefore a very great probability that whatever may be the nature of the unknown causes which determine the positions of the cometary orbits, it is not such as to render different inclinations unequally probable.

If the question had been to assign the limits within which it is as probable that the mean of the inclinations will fall as not, we should have had $\Theta=\frac{1}{2}$, and consequently (from the table) $\tau=\cdot476936$, and the limits would have been $45°\mp 90°\times\cdot476936\div\surd(6\times 138)$, which is found on calculation to be $45°\mp 1°{\cdot}5$. On the supposition, therefore, that all inclinations are equally probable, it is one to one that the mean of 138 inclinations will fall between $43\frac{1}{2}°$ and and $46\frac{1}{2}°$, or at least not exceed those limits.

129. On the same hypothesis of an equal probability of all possible values, if we suppose the mean value of A to be 0, we have then $a=-b$, and φx becomes $1\div 2a$, whence the limits corresponding to a given value of Θ (127) become $0\mp 2\tau b:\surd(6h)$. Let $\Theta=\frac{1}{2}$, whence $\tau=\cdot476936$, and suppose $h=600$. With these values the limits become $0\mp\cdot016b$ nearly; that is to say, it is an even wager that the average of 600 observations will not differ from the true mean value of A more than the sixteen-thousandth part of a or b, what is the greatest possible difference.

130. As a second hypothesis, suppose the chance of a given value of A to decrease uniformly as the magnitude increases from 0 to $\pm a$; then φx will be found as follows: Let $\varphi x=\beta$ when $a=0$; we have then by the hypothesis $\varphi x:\beta=(a-x):a$, whence $\varphi x=(a-x)\beta\div a$, and consequently $\int\varphi x dx=\beta x-\beta x^2\div 2a$, which, from $x=0$ to $x=+a$, becomes $\frac{1}{2}\beta a$. But $\int\phi x dx$ from $x=-a$ to $x=+a$ is 1 (errors beyond those limits being supposed impossible), therefore from $x=0$ to $x=+a$, $\int\phi x dx=\frac{1}{2}$, and consequently $\frac{1}{2}\beta a=\frac{1}{2}$, or $\beta=1\div a$. Hence $\phi x=(a-x)\div a^2$, from which the value of c is easily deduced, that of k being 0, as in the former case.

131. Although the function φx which represents the law of facility of the different values of A is in general unknown, its form may be assigned if we assume that it is subject to certain conditions, which, from the nature of the thing, must be very nearly, if not absolutely true, in most practical cases: 1st, That the chance of an error diminishes as the magnitude of the error increases, and for errors beyond a certain limit vanishes altogether; and, 2d, that positive and negative errors, of equal magnitude, are equally probable. The last condition is equivalent to the assumption that the average of the observed values is the true mean value. For simplification, we suppose the chance of an error of a given magnitude to remain constant in all the trials.

132. Let x, x', x'', &c. be a series of values of A, the sum of which is s, and the number h, and make $m=s\div h$, then m is the arithmetical mean or average, which by hypothesis is the true value of the phenomenon A. Let $x-m=\Delta$, $x'-m=\Delta'$, $x''-m=\Delta''$, &c., so that Δ, Δ', Δ'', &c. are the errors of x, x', x'', &c. Now, the most probable single error is 0; and the probability of obtaining an error of a given magnitude Δ in any observation is obviously the same as that of obtaining a given value of x; therefore $\varphi x=\varphi(x-m)=\varphi\Delta$; so that $\varphi\Delta$ is the probability of a single error being exactly Δ. In like manner, the probability of an error $=\Delta'$ is $\varphi\Delta'$; and if we take P to denote the probability of a given system of errors, Δ, Δ', Δ'', &c., then the errors being supposed independent of each other, we have (7)

$$P=\varphi\Delta\,.\,\varphi\Delta'\,.\,\varphi\Delta'', \text{ \&c.}$$

Let this system be assumed to be the most probable result of the observations, then P is a maximum, and its differential co-efficient zero. Taking the logarithms of both sides of the equation, differentiating, and making $d\log.\varphi\Delta=\varphi'\Delta d\Delta$, and $dP\div d\Delta=0$, we obtain

$$0=\varphi'\Delta+\varphi'\Delta'+\varphi'\Delta''+, \text{ \&c.},$$

an equation which may be otherwise written

$$0=\Delta\frac{\varphi\,\Delta}{\Delta}+\Delta'\frac{\varphi'\Delta'}{\Delta'}+\Delta''\frac{\varphi'\Delta''}{\Delta''}+, \text{ \&c.}$$

This is the conditional equation of the most probable system of errors. But the hypothesis of the average being the true value, furnishes this other equation,

$$0=(x-m)+(x'-m)+(x''-m)+, \text{ \&c.}$$

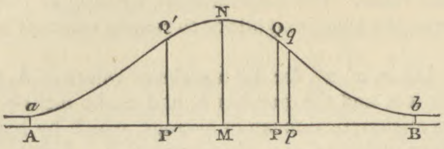
or, which is the same, $0=\Delta+\Delta'+\Delta''+$, &c.; and on comparing this with the above conditional equation, it is evident that they can only be both true simultaneously on the supposition of $\frac{\varphi'\Delta}{\Delta}=\frac{\varphi'\Delta'}{\Delta'}=\frac{\varphi'\Delta''}{\Delta''}=$, &c. Hence it follows that $\varphi'\Delta\div\Delta$ is independent of any particular value of Δ, or is equal to a constant, which we shall call K. We have then

$$\frac{\varphi'\Delta}{\Delta}=\frac{d\,.\log.\,\varphi\Delta}{\Delta d\Delta}=\text{K}.$$

The integral of this expression is $\log.\,\varphi\Delta=\frac{1}{2}\text{K}\Delta^2+$ const., which, making the last constant $=\log.$ H, and passing to numbers, gives $\varphi\Delta=\text{H}e^{\frac{1}{2}\text{K}\Delta^2}$. It now only remains to determine the two constants H and K. With respect to K, as we suppose the most probable value of Δ to be 0, and that $\varphi\Delta$ diminishes as Δ increases, it is obvious that K must be negative. Assume $\frac{1}{2}\text{K}=-\gamma$, and the formula becomes $\varphi\Delta=\text{H}e^{-\gamma\Delta^2}$. For the determination of H we have the equation $\int\varphi\Delta d\Delta=1$, the limits of the integral being $-a'$ and $+a'$, where $a'=\frac{1}{2}(b-a)$, a and b being the limiting values of x. But it is to be observed, that as all values of Δ exceeding the limits $\pm a'$ are supposed to be impossible, or at least to be so improbable that it is unnecessary to take account of them, the value of the integral $\int\varphi\Delta d\Delta$ from $\Delta=-a'$ to $\Delta=+a'$ will not be altered by extending the limits from − infinity to + infinity. We have therefore $\int_{-\infty}^{+\infty}\varphi\Delta d\Delta=1$. Let $\Delta=t\div\surd\gamma$, then $d\Delta=dt\div\surd\gamma$, and $\varphi\Delta=\text{H}e^{-\gamma\Delta^2}=\text{H}e^{-t^2}$, on substituting which in the las equation, and observing that from $t=-\infty$ to $t=+\infty$ we have $\int e^{-t^2}dt=\surd\pi$ (96), we find $(\text{H}\div\surd\gamma)\surd\pi=1$, and $\text{H}=\surd(\gamma\div\pi)$. Whence, finally, $\varphi\Delta=\surd(\gamma\div\pi)e^{-\gamma\Delta^2}$.

133. The general properties of the function now found

may be illustrated by means of a curve line. Let aNb be



a curve of which $\varphi\Delta$ is the ordinate corresponding to the absciss Δ. Let AB be its axis, and MN its greatest ordinate. Suppose the origin to be placed at M, draw PQ an ordinate at any point P, and pq indefinitely near to PQ, and make $MB = a'$, $MA = -a'$, $MP = \Delta$, and $PQ = \varphi\Delta$; then as was shewn in (124), PQqp, the element of the area, represents the chance of an error lying between Δ and $\Delta + d\Delta$, that is, of an error greater than MP but less than Mp. Now, if $\varphi\Delta = \sqrt{(\gamma \div \pi)}e^{-\gamma\Delta^2}$ the function will not be changed by changing Δ into $-\Delta$; therefore $\varphi\Delta = \varphi(-\Delta)$, and the curve is symmetrical on both sides of MN, as it obviously ought to be according to the hypothesis; for on making $MP' = MP$, then positive and negative errors of equal magnitude being equally probable, we must have $P'Q' = PQ$. Again, since $e^{-\gamma\Delta^2}$ diminishes rapidly as Δ increases, the curve at a short distance from MN must approach very near to its axis AB; but as the function only vanishes when Δ is infinite, the curve will not meet the axis at any finite distance from MN. This curve, therefore, can only represent approximately the law of facility, inasmuch as it is supposed that errors beyond a certain limit are impossible; but on account of the rapid diminution of the ordinate at a short distance from MN, the chance of an error exceeding a small value of Δ, as MB, becomes insensible. Hence the limits of the integrals in respect of Δ may be extended without sensibly altering their values from $\Delta = \pm a'$ to $\Delta = \pm\infty$.

134. It is now necessary to find the special quantities k, k', and c. Substituting Δ for x, and observing that as the law of the chances is here supposed to remain constant, we have $k = k_n$, $k' = k'_n$, the formulæ in (119) become $k = \int \Delta\varphi\Delta d\Delta$, $k' = \int \Delta^2\varphi\Delta d\Delta$. Hence on making $\varphi\Delta = \sqrt{(\gamma \div \pi)}e^{-\gamma\Delta^2}$, we have

$$k = \sqrt{\frac{\gamma}{\pi}}\int \Delta e^{-\gamma\Delta^2} d\Delta = \sqrt{\frac{\gamma}{\pi}} \cdot \frac{1}{2\gamma}\int d . e^{-\gamma\Delta^2} = \frac{1}{2\sqrt{(\gamma\pi)}}e^{-\gamma\Delta^2}.$$

When Δ becomes infinite, this becomes 0, therefore from $\Delta = -\infty$ to $\Delta = +\infty$, $k = 0$. This is an obvious consequence of the symmetry of the curve, for the centre of gravity is necessarily in the straight line MN.

With respect to k' we may proceed thus. We have $k' = \int \Delta^2\phi\Delta d\Delta = \sqrt{(\gamma \div \pi)}\int \Delta^2 e^{-\gamma\Delta^2} d\Delta$. But from the principles of the differential calculus,

$$d . \Delta e^{-\gamma\Delta^2} = e^{-\gamma\Delta^2}d\Delta - 2\gamma\Delta^2 e^{-\gamma\Delta^2}d\Delta,$$

therefore, integrating and transposing,

$$\int \Delta^2 e^{-\gamma\Delta^2} d\Delta = -\frac{1}{2\gamma}\Delta e^{-\gamma\Delta^2} + \frac{1}{2\gamma}\int e^{-\gamma\Delta^2} d\Delta.$$

Now, from $\Delta = -\infty$ to $\Delta = +\infty$, the term of this equation which is not under the sign of integration vanishes, and $\int e^{-\gamma\Delta^2} d\Delta = \sqrt{(\pi \div \gamma)}$ (from (96), on substituting t^2 for $\gamma\Delta^2$), therefore $\int \Delta^2 e^{-\gamma\Delta^2} d\Delta = (1 \div 2\gamma)\sqrt{(\pi \div \gamma)}$; and consequently $k' = 1 \div 2\gamma$.

In (119) we assumed $c = \frac{1}{2}(k' - k^2)$; therefore in the present case $c = \frac{1}{2}k'$, whence $c = 1 \div 4\gamma$, or $\gamma = 1 \div 4c$.

135. The expressions which have now been found for the function which represents the probability of an error, and the limits corresponding to an assigned degree of probability, are given in terms of the indeterminate constant γ (or c), which depends on the nature of the observation, and therefore, where instruments are requisite, on the goodness of the instrument and the skill of the observer. This constant is called by Laplace the *modulus* of the law of facility. It cannot, in general, be assigned *a priori*; but if we assume that positive and negative departures from the mean are alike probable, which is the most plausible hypothesis the nature of the thing admits of, an approximation to its value, in respect of observations of a given kind, may be deduced with great probability from the results of a large series of observations of the same kind already made. We now proceed to give the analysis by which this is accomplished, following the method of Poisson. The approximation is carried only to quantities of the order $1 \div \sqrt{h}$; terms having h for a divisor are neglected on account of their smallness, h being supposed a large number.

136. In the expression for Q in (119), suppose $\psi = \delta$, and consequently $\psi - \delta = 0$, $\psi + \delta = 2\delta$, and write also z for $\theta \div \sqrt{(hc)}$; the equation then becomes

$$Q = \frac{2}{\pi}\int_0^\infty e^{-\theta^2}\cos(hkz - \delta z)\sin\delta z . \frac{\delta\theta}{\theta}$$

$$+ \frac{2g}{\pi c\sqrt{(hc)}}\int_0^\infty {}^{-\theta^2}\sin(hkz - \delta z)\sin\delta z . \theta^2 d\theta,$$

and Q is the probability that s, the sum of the values of A given by all the observations, will lie between 0 and 2δ. If therefore, we suppose δ to be variable, the differential of this expression taken with respect to δ, will express the infinitely small chance of the sum of the values being 2δ exactly. Differentiating, and observing that if u and v denote any two arcs, the trigonometrical formulæ give

$$\sin(u - v)\sin v + \cos(u - v)\cos v = \cos(2v - u),$$

$$-\cos(u - v)\sin v + \sin(u - v)\cos v = -\sin(2v - u),$$

we shall find

$$\frac{dQ}{d\delta}d\delta = \frac{2d\delta}{\pi}\int_0^\infty e^{-\theta^2}\cos(2\delta z - hkz)\frac{zd\theta}{\theta}$$

$$-\frac{2gd\delta}{\pi c\sqrt{(hc)}}\int_0^\infty e^{-\theta^2}\sin(2\delta z - hkz)z\theta^2 d\theta.$$

Let t be a variable quantity, and assume $2\delta = hk + 2t\sqrt{(hc)}$, whence $d\delta = dt\sqrt{(hc)}$, and let the corresponding value of $\frac{dQ}{d\delta}d\delta$ be denoted by qdt, we shall have, on substituting these values, and replacing z by $\theta \div \sqrt{(hc)}$, $qdt = \frac{2dt}{\pi}$

$$\int_0^\infty e^{-\theta^2}\cos(2t\theta)d\theta - \frac{2gdt}{\pi c\sqrt{(hc)}}\int_0^\infty e^{-\theta^2}\sin(2t\theta)\theta^3 d\theta.$$

The two integrals in this equation are found from the formula in (121). Writing $2t$ for u, that formula gives

$$\int_0^\infty e^{-\theta^2}\cos(2t\theta)d\theta = \tfrac{1}{2}\sqrt{\pi} . e^{-t^2};$$

and if this last equation be differentiated in respect of t, three times in succession, the result will be

$$\int_0^\infty e^{-\theta^2}\sin(2t\theta)\theta^3 d\theta = \tfrac{1}{4}\sqrt{\pi}(3te^{-t^2} - 2t^3 e^{-t^2});$$

whence, if we make $V = \frac{g}{2c\sqrt{(hc)}}(3t - 2t^3)$, we shall have

$$qdt = (1 \div \sqrt{\pi})(1 - V)e^{-t^2}dt,$$

where V is a quantity containing only uneven powers of t, and of the order $1 \div \sqrt{h}$, so that when multiplied by another of the same order, the product will be of the order $1 \div h$, and will therefore be rejected in the present approximation. This value of qdt is the probability that s will be precisely 2δ or $hk + 2t\sqrt{(hc)}$, or it is the infinitely small probability of the equation

$$s = hk + 2t\sqrt{(hc)}.$$

137. In order to apply this result to the determination of the probable limits in terms of observations actually

made, it is necessary to remark that the analysis by means of which it has been obtained is grounded on the very general supposition that the thing to be measured may be any function whatever of the quantity observed; for the infinitely small chance of a particular value of the function is evidently the same as that of the corresponding value of the quantity, and is consequently $\phi_n x dx$. Let X therefore be a function of x, and let K, C, T, be what k, c, t become when X is substituted for x, the above equation then becomes

$$\Sigma X = hK + 2T\sqrt{(hC)},$$

the symbol Σ including all the h values of X; and the probability of this equation is an expression of the same form as that which is represented by qdt.

138. Hitherto no restriction has been made with respect to ϕx; we now introduce the hypothesis that positive and negative departures from the mean of equal magnitude are equally probable, and consequently that the curve representing the law of facility is symmetrical, but shall suppose the chances of a particular value, or a particular error, to vary in the different trials. Let the origin be transferred to the centre of gravity, the absciss of which $= k$, and let $x - k = \Delta$, $x' - k = \Delta'$ &c. We have then by (132) $\phi x = \phi\Delta$, $\int x\phi x dx = \int \Delta\phi\Delta d\Delta$, $\int x^2\phi x dx = \int\Delta^2\phi\Delta d\Delta$, the integration in respect of Δ being from $-\infty$ to $+\infty$. The special quantities k and k' then become $k = (1 \div h)\Sigma\int\Delta\phi_n\Delta d\Delta = 0$, $k' = (1 \div h)\Sigma\int\Delta^2\phi_n\Delta d\Delta$, whence

$$c = (1 \div 2h)\Sigma\int\Delta^2\phi_n\Delta d\Delta.$$

The object is now to eliminate $\phi_n\Delta$, and determine c in terms of the observations.

139. Let $\lambda_n = x$ be the observed value of A in the nth observation, then $\lambda_n - k = \Delta$ is the true error of the observation. Let the function denoted by X in (137) be $(\lambda_n - k)^2 = \Delta^2$, and the corresponding value of K (since in this case, $K = (1 \div h)\Sigma\int X\phi_n x dx$) becomes $K = (1 \div h)\Sigma\int\Delta^2\phi_n\Delta d\Delta$. Comparing this with the value of c found above, we have $K = 2c$; therefore on substituting these values of X and K in the equation (137), and assuming t' and c' to be the values of T and C when $X = (\lambda_n - k)^2$, we get $\Sigma(\lambda_n - k)^2 = 2hc + 2t'\sqrt{(hc')}$, whence

$$c = (1 \div 2h)\Sigma(\lambda_n - k)^2 - t'U' \qquad (1)$$

(U being a quantity of the order $1 \div \sqrt{h}$); and the probability of this equation is

$$q'dt' = (1 \div \sqrt{\pi})(1 - V')e^{-t'^2}dt',$$

where V' is a function containing only uneven powers of t', and of the order $1 \div \sqrt{h}$.

In the equation (137) suppose $X = x = \lambda_n$, and let t'' and c'' be the corresponding values of T and C, then since on this supposition $K = k$, the equation becomes $\Sigma\lambda_n = hk + 2t''\sqrt{(hc'')}$, whence

$$k = (1 \div h)\Sigma\lambda_n - t''U'', \qquad (2)$$

(U'' being of the order $1 \div \sqrt{h}$); and the probability of this equation is

$$q''dt'' = (1 \div \sqrt{\pi})(1 - V'')e^{-t''^2}dt'',$$

where V'', like V' and V, contains only uneven powers of t'' and is of the order $1 \div \sqrt{h}$.

140. The two equations (1) and (2) may be regarded as two distinct events, having the respective probabilities now assigned to them, and therefore the probability of their being true simultaneously is the product of their respective probabilities, and is accordingly (neglecting the product $V'V''$ which is a quantity divided by h),

$$q'q''dt'dt'' = (1 \div \pi)(1 - V' - V'')e^{-t'^2}e^{-t''^2}dt'dt''.$$

Let the value of k given by equation (2) be substituted in (1), and the expression now given will accordingly be the probability of the resulting equation, namely,

$$c = \frac{1}{2h}\Sigma(\lambda_n - \frac{1}{h}\Sigma\lambda_n + t'U')^2 - t''U''$$

Let $m = (1 \div h)\Sigma\lambda_n$, then m is the average or arithmetical mean of the observed values, and $\lambda_n - m$ the *reputed* error of the observation. The last equation will then become $c = (1 \div 2h)\Sigma(\lambda_n - m + t'U')^2 - t''U''$; or, rejecting $(t'U')^2$ which is of the order $1 \div h$,

$$c = (1 \div 2h)\Sigma\{(\lambda_n - m)^2 + 2(\lambda_n - m)t'U'\} - t''U''.$$

For the sake of abridging let us also assume

$$\mu = (1 \div h)\Sigma(\lambda_n - m)^2, \quad \nu = (1 \div h)\Sigma(\lambda_n - m)t',$$

so that μ is the mean of the squares of the errors, or *mean square* of the errors, and the equation becomes

$$c = \tfrac{1}{2}\mu + \nu U' - t''U'', \qquad (3)$$

the probability of which is $q'q''dt'dt''$.

141. Now, by (121), we have the probability Θ that $s \div h$, or $\Sigma\lambda_n \div h = m$ the arithmetical mean of the observed values of A, will fall within the limits $k \mp 2\tau\sqrt{(c \div h)}$. Substituting in those limits the above value of c, and observing that $(\frac{1}{2}\mu + \nu U' - t''U'')^{\frac{1}{2}} = \sqrt{(\frac{1}{2}\mu)} + N(\nu U' - t''U'') + \&c.$, and that U' and U'' being of the order $1 \div \sqrt{h}$, when divided again by $\sqrt{h}$ are to be rejected, the limits become

$$k \mp 2\tau\sqrt{(\tfrac{1}{2}\mu \div h)}, \text{ or } k \mp \tau\sqrt{(2\mu \div h)},$$

and the probability of these being the true limits is Θ multiplied into the probability of the equation $c = \frac{1}{2}\mu + \nu U' - t''U''$; and is therefore (140)

$$(1 \div \pi)\Theta(1 - V' - V'')e^{-t'^2}e^{-t''^2}dt'dt''.$$

142. The expression now obtained is the infinitely small probability of the limits $k \mp \tau\sqrt{(2\mu \div h)}$ of the average m, in respect of the particular value of s, for which we have deduced the equation (3). But for every value of s between the limits 0 and 2δ, there will be an equation corresponding to (3); therefore, in order to have the whole probability of those limits, the integral of the expression must be found for all values of t' and t''. From the nature of the expressions $e^{-t'^2}$ and $e^{-t''^2}$ as well as the consideration that errors beyond a certain magnitude, though possible, are wholly improbable, it is evident that the integration may be extended without sensible error from $-\infty$ to $+\infty$; and since the functions V' and V'' contain only uneven powers of t' and t'', the terms into which they enter, disappear in the integrations between those limits (See Lacroix, *Calcul Diff. et Integral*, tom. iii. p. 506). Now, from $t' = -\infty$ to $t' = +\infty$ we have (96) $\int e^{-t'^2}dt' = \sqrt{\pi}$; and $\int e^{-t''^2}dt'' = \sqrt{\pi}$; therefore

$$\frac{1}{\pi}\Theta\iint(1 - V' - V'')e^{-t'^2}e^{-t''^2}dt'dt'' = \Theta.$$

The result of the preceding analysis is therefore that on the hypothesis of positive and negative errors of equal magnitude being equally probable, and on rejecting terms divided by h (the number of the observations may be always so great as to render such terms insensible), we may substitute $\frac{1}{2}\mu$ for c in the limits of the error to be apprehended, without sensibly altering the probability, and consequently there is the probability $\Theta = \frac{2}{\sqrt{\pi}}\int_0^\tau e^{-t^2}dt$ that the true mean value k of the phenomenon A will lie between the limits

$$m \pm 2\tau\sqrt{(\tfrac{1}{2}\mu \div h)}, \text{ or } m \pm \tau\sqrt{(2\mu \div h)},$$

which contain only quantities given by observation.

On this hypothesis we have also (138) $c = (1 \div 2h)\Sigma\int\Delta^2\phi_n\Delta d\Delta$, or, supposing the law of facility to remain constant during the trials, $c = \frac{1}{2}\int\Delta^2\phi\Delta d\Delta$, therefore $\mu = \int\Delta^2\phi\Delta d\Delta$; that is to say, the mean of the squares of the actual errors may be taken for the sum of the squares of the possible errors multiplied by their respective probabilities. It is important to remark that as the observations become more numerous, the quantity μ, the mean of the squares of the errors, converges more and more to a constant quantity, and finally becomes independent of the number of observations.

143. The limits now found may be otherwise expressed. By hypothesis, $m=(1\div h)\Sigma\lambda_n=$ the arithmetical mean of the observed values, and $\mu=(1\div h)\Sigma(\lambda_n-m)^2=$ the mean of the squares of the reputed errors. Now $(\lambda_n-m)^2=\lambda_n^2-2\lambda_n m+m^2$, and $(1\div h)\Sigma 2\lambda_n m=2m(1\div h)\Sigma\lambda_n=2m^2$; therefore $\mu=(1\div h)\Sigma\lambda_n^2-m^2$, that is to say, the mean of the squares of the observations minus the square of the mean. Hence the limits, corresponding to a given probability Θ, of the difference between the average of all the observations and the true value, are expressed by either of these formulæ

$$\pm\tau\surd\{(2\times\text{ mean square of errors}\div h\},$$

$$\pm\tau\surd\{2\times\text{ mean square of obs.}-(\text{mean of obs.})^2\}\div\surd h,$$

h being the number of observations, and the relation between Θ and τ being given by the table. Generally speaking, the first of these formulæ is the most convenient for calculation.

144. Let l be the limit of the error to be feared in taking the average of the observations as the true result, then $l=\tau\surd(2\mu\div h)$, and $\tau=l\surd(h\div 2\mu.)$ Now when τ is constant, that is, for a given probability Θ, the determination will be more exact in proportion as l is a smaller number, and the precision will therefore be proportional to $\surd(h\div 2\mu)$. Hence $\surd(h\div 2\mu)$ is called by Gauss the *measure of the precision* of the determination. Suppose two series of observations to have been made for the determination of an element, the comparative accuracy of the results will depend on two things, the number of observations in each series, and the amount of the squares of the errors in each. If the number of observations is the same in both series, the precision of each result will be inversely as the square root of the sum of the squares of the errors, and the presumption of accuracy is in favour of that result with respect to which the sum of the squares of the errors is less than in the other. On the other hand, if the mean square of the errors is the same in both series, then the observations are alike good in both, and their relative values of the two results are directly as the square roots of the number of observations in each series. Hence, in order that one determination may be twice as good as another, it must be founded on four times the number of equally good observations. These considerations are very important, in comparing tables of mean values of whatever kind, for example, of the probabilities of life at the different ages, and in estimating risks which depend upon them.

145. Astronomers employ the terms, *weight*, *probable error*, and *mean error*, of a result, to denote certain functions of μ, the mean square of the errors. The square of the quantity which measures the precision of the result, is called the *weight* of the determination. Denoting the weight by w, we have therefore

$$w=h\div 2\mu=h^2\div 2\Sigma(\lambda_n-m)^2,$$

or the weight is equal to the square of the number of observations divided by twice the sum of the squares of the errors. Substituting this in the expression of the limits, we have $l=\tau\div\surd w$, and $\tau=l\surd w$; that is to say, for a given probability Θ, the limits of the error to be apprehended in taking the average as the true result are reciprocally proportional to the square root of the weight. When observations of different kinds, or results deduced from observation, are compared with each other, their relative weights (supposing the number of observations the same) are inversely as μ, and are expressed numerically by taking the weight of a certain series of observations as the unit of weight.

146. The *probable error* of the determination is that which corresponds to the probability $\Theta=\frac{1}{2}$. For $\Theta=\frac{1}{2}$ we have $\tau=\cdot 476936$; whence $\tau\surd 2=\cdot 674489$, and the formula $m\pm\tau\surd(2\mu\div h)$ becomes $m\pm\cdot 674489\surd(\mu\div h)$; whence

$$\text{probable error }=\cdot 674489\surd(\mu\div h).$$

147. The *mean error* of the result of a large number of observations may be deduced from the general formula in (136) as follows. That formula gives $qdt=(1\div\surd\pi)(1-\text{V})e^{-t^2}dt$ for the probability that the sum of the observed values will be $2\delta=hk+2t\surd(hc)$ exactly. Dividing the sum by h, qdt is also the probability that the average value given by all the observations will be exactly $k+2t\surd(c\div h)$. Now, on the hypothesis that positive and negative departures from the mean are equally probable, and supposing the origin of the co-ordinates to be transferred to the centre of gravity of the curve of mean probability, we have $k=0$, and $qdt=(1\div\surd\pi)(1-\text{V})e^{-t^2}dt$ is the infinitely small chance of the average error being $2t\surd(c\div h)$ exactly. Multiplying therefore this error into the chance of its taking place, and integrating the product from $t=0$ to $t=\infty$, we shall have the *mean* error, or *mean risk* of all the possible average errors affected with the positive sign. Now, observing that V represents a quantity divided by $\surd h$, and therefore when multiplied by $2t\surd(c\div h)$ becomes of the order $1\div h$, and may consequently be rejected, the product of the average error $2t\surd(c\div h)$ into its probability is $2\surd(c\div\pi h)\times te^{-t^2}dt$; and since $\int te^{-t^2}dt=\frac{1}{2}\int d.e^{-t^2}=\frac{1}{2}e^{-t^2}$, which from $t=0$ to $t=\infty$ becomes simply $\frac{1}{2}$, the integral of the above product from $t=0$ to $t=\infty$ is $\surd(c\div\pi h)$. Substituting for c its value (142) $=\frac{1}{2}\mu$, this result becomes $\surd(\mu\div 2\pi h)$; whence on computing $\surd(1\div 2\pi)$ we obtain

$$\text{mean error of series }=.398942\surd(\mu\div h).$$

This is the mean error or mean risk in respect of positive errors alone, or on the supposition that negative errors are not taken into account. But as positive and negative errors are equally likely, the mean error in respect of negative errors is the same quantity, whence the mean error in respect of errors of both kinds is $.797884\surd(\mu\div h)$. This is usually called the *average* error. The mean error differs from the probable error in this respect, that it depends on the magnitude of individual errors, as well as on the proportion in which errors of different magnitudes occur. The probable error is independent of the magnitude.

148. When the quantity μ (the mean square of the errors) has been found from a series of observations, the precision, weight, probable error, and mean error, of a coming observation of the same kind are found by supposing $h=1$ in the above expressions, and are respectively

precision . . $=\surd(1\div 2\mu)$
weight . . $=1\div 2\mu$
probable error $=.674489\surd\mu$
mean error . $=.398942\surd\mu$.

149. The preceding formulæ give the limits of the error to be feared in determining the value of a quantity from a series of observations, when the thing to be determined is that on which the observations are immediately made. We have now to apply the formulæ to the cases in which the quantity sought is not observed itself, but is a function of several others, which are separately determined by observation. The following problem is important:

Let u be a given function of a number of unknown quantities, x, x', x'', &c.; it is required to assign the limits of the probable error in the determination of U, and the weight of the result, when values of x, x', x'', found from observations independent of each other, and respectively affected with the probable errors $\varrho\surd\mu$, $\varrho\surd\mu'$, $\varrho\surd\mu''$, &c. ($\varrho=.674489$) are adopted instead of the true but unknown values of those quantities.

Let $u=f(x, x', x'', \text{&c.})$ be the given function, λ, λ', λ'', &c. observed values of x, x', x'', &c. and make $\lambda-x=e$,

$\lambda' - x' = e'$, $\lambda'' - x'' = e''$, &c. so that e, e', e'', &c. are the errors of observation, supposed to be so small that their squares may be rejected. Make $\frac{du}{dx} = a$, $\frac{du}{dx'} = a'$, $\frac{du}{dx''} = a''$, &c., then a, a', a'', are given quantities; and on substituting $x+e$, $x'+e'$, $x''+e''$ for x, x', x'', respectively, in the equation $u=f(x, x', x'', \&c.)$, and supposing u to become $u+E$ when the substitutions are made, so that E is the corresponding error of u, we have, on expanding u by Taylor's theorem,

$$E = ae + a'e' + a'e'' + \&c.$$

in respect of a single observation of each of the quantities. Taking the square of both sides of the equation, we have

$$E^2 = a^2e^2 + a'^2e'^2 + a''^2e''^2 + \&c. + 2aa'ee' + 2aa''ee'' + 2a'a''e'e'' + \&c.$$

Now since positive and negative errors are supposed equally probable, the sums of the products ee', ee'', $e'e''$, &c. or their mean values, become each $= 0$; therefore

$$\Sigma E^2 = a^2\Sigma e^2 + a'^2\Sigma e'^2 + a''\Sigma e''^2 + \&c.$$

Taking the mean value of each of these sums, and observing that μ the mean value of Σe^2 is independent of the number of observations (142), and assuming M to be the mean value of ΣE^2, we get

$$M = a^2\mu + a'^2\mu' + a''^2\mu'' + \&c.$$

This equation contains the solution of the problem, for all the functions of the error are given in terms of M. The probable error is $\cdot674489\sqrt{M}$.

150. Let W be the weight of the determination, and w, w', w'', &c. the weights corresponding to μ, μ', μ'', &c. then by the definition of weight, w is reciprocally proportioned to μ, and W to M; and we have by substitution,

$$W = 1 \div \left(\frac{a^2}{w} + \frac{a'^2}{w'} + \frac{a''^2}{w''} + \&c.\right).$$

If the weights are supposed all equal, this becomes

$$W = \frac{w}{a^2 + a'^2 + a''^2 + \&c.}$$

Suppose the errors e, e' e'', &c. to be respectively multiplied by numbers proportional to the square roots of the weights, (which is equivalent to supposing all the observations to have the same degree of precision measured by $\sqrt{(\mu w)}$), then the value of M becomes

$$M = a^2\mu w + a'^2\mu' w' + a''^2\mu'' w'' + \&c.$$

But w being reciprocally as μ, we have $\mu w = \mu' w' = \mu'' w''$, &c. $= 1$, therefore

$$W = \frac{1}{a^2 + a'^2 + a''^2 + \&c.}.$$

SECT. X. OF THE METHOD OF LEAST SQUARES.

151. In the determination of astronomical and physical elements from the data of observation, the thing which is actually observed is for the most part not the element which is sought to be determined, but a known function of that element. Thus, if V be a given function of X determined by the equation $V=F(X)$, the quantity observed may be a value of V, whilst the element sought to be determined is X. If the observation could give the value of V with absolute accuracy, then X would also be absolutely known; but as all observations are affected with certain errors of greater or less amount, owing to the imperfections of instruments or of sense, or the ever varying circumstances under which they are made, an exact value of X cannot be found from any single observation; and in order to obtain the utmost precision, it is necessary to employ a great number of observations, repeated under every variety of circumstance by which the result can be supposed to be affected.

152. The observed quantity V, instead of being a function of a single element X, may be a function of several elements X, Y, Z, &c.; for example, V may be the position of a planet, in which case it is a function of the six elements of the orbit, for the determination of which the observation is made. Each observation gives rise to an equation of this form, $V=F(X, Y, Z, \&c.)$; therefore when the number of equations is just equal to the number of unknown quantities, the problem is determinate; and supposing F to be an algebraic function, the values of X, Y, Z, &c. may be found by the ordinary methods of elimination. If the number of equations is less than the number of unknown quantities, the problem is indeterminate; but if greater, it may be said to be more than determinate, inasmuch as the equations may be combined in an infinite number of ways, each distinct combination giving a different value of the elements. It therefore becomes a question of the utmost importance to the perfection of the sciences of observation, to assign the particular combination which gives the most advantageous results, or values of X, Y, Z, &c. affected with the smallest probable errors.

153. As approximate values of the elements are in all cases either already known, or can be easily found, the object of accumulating observations is the correction of the approximate values. Let V be the true value of the thing observed, V_0 an approximate value, however found, X the true value of the element sought, X_0 an approximate value, corresponding to V_0, so that we have the two equations $V=F(X)$, $V_0=F(X_0)$; also, let the observed value of V in any observation be L, and make

$$v = V - L, \quad l = V_0 - L,$$

then v is the true but unknown error of the observation, and l its reputed error, that is to say, the difference between the computed value of the function and the result of the observation. Now if we assume x to represent the true correction of the approximate element, so that $X=X_0+x$, then, on substituting X_0+x for X in the function F, we get $V=F(X_0+x)$; whence, expanding the function by Taylor's theorem, and rejecting terms multiplied by x^2 and higher powers of x, because x is a very small quantity

$$V = V_0 + \frac{dV_0}{dX}x.$$

Let us now denote the differential coefficient, which is a known quantity, by a; then, observing that $V-V_0=v-l$, the equation becomes $v=l+ax$; that is to say, the true error of the observation is a linear function of the correction of the element.

154. In like manner, when there are several elements, X, Y, Z, &c.; on making $\frac{dV_0}{dX}=a$, $\frac{dV_0}{dY}=b$, $\frac{dV_0}{dZ}=c$, &c. a single observation furnishes the equation

$$v = l + ax + by + cz + \&c.,$$

and a series of observations, whose errors are respectively v, v', v'', &c. gives a system of linear equations equal in number to the number of observations; namely,

$$\begin{aligned} v &= l + ax + by + cz + \&c. \\ v' &= l' + a'x + b'y + c'z + \&c. \qquad (1) \\ v'' &= l'' + a''x + b''y + c''z + \&c. \\ &\&c. \end{aligned}$$

and the object is to give such values to x, y, z, &c. that the errors v, v', v'', &c. in respect of the whole of the observations, shall be the least possible. The equations being supposed independent of each other, if their number is just equal to that of the unknown quantities, the errors v, v', v'', &c. can be made all zero; but if, as is usually the case, there are more equations than unknown quantities, it is impossible by any means whatever to annihilate the whole of them, and therefore all that can be accomplished is to find the system of values of x, y, z, &c. which most nearly, and with the greatest probability, satisfies the whole of the equations. If the observations are not all equally good, the equations are supposed to be each multiplied by a number proportional to the square root of the presumed weight of the observation on which it depends, in order that they may all have the same degree of precision.

155. As the question is to find the most probable values of x, y, z, &c. the first thing necessary is to express each of these elements in terms of the observations. Suppose k, k', k'', &c. to be a system of indeterminate quantities, independent of x y, z, &c. and let the first of the above conditional equations be multiplied by k, the second by k', the third by k'', and so on; then adding the products, if k, k', k'', &c. be determined so as to make the coefficient of x equal to unit, and those of y, z, &c. each equal to 0; that is to say, so as to satisfy the equations

$$\begin{aligned} &ka+k'a'+k''a''+\text{\&c.}=1\\ &kb+k'b'+k''b''+\text{\&c.}=0 \qquad (2)\\ &kc+k'c'+k''c''+\text{\&c}=0\\ &\text{\&c.}\end{aligned}$$

we shall then have $x=\mathrm{K}+kv+k'v'+k''v''+$ &c. where K is a quantity independent of v, v', v'', &c. Hence x is found $=\mathrm{K}$, with an error $=kv+k'v'+k''v''+$&c.; and the *weight* of the determination, by the formula in (150), is $\dfrac{1}{k^2+k'^2+k''^2+\text{\&c}}$. The weight of the determination is consequently greater in proportion as $k^2+k'^2+k''^2+$ &c. is smaller; and hence of all the possible systems of indeterminate coefficients, k, k', k'', &c. which satisfy the equations (2), the system which gives the most probable value of x, or the most advantageous result, is that for which $k^2+k'^2+k''^2+$&c. is an absolute minimum.

156. We have now to find, in terms of known quantities, values of the indeterminate coefficients k, k', k'', &c. which satisfy the condition of the minimum. For the sake of abridging, let us denote the aggregate of the products $aa+a'a'+a''a''+$ &c, by $\mathrm{S}(aa)$, that of $ab+a'b'+a''b''+$ &c. by $\mathrm{S}(ab)$, and so on, and also assume

$$\begin{aligned} \xi&=av+a'v'+a''v''+\text{\&c.}\\ \eta&=bv+b'v'+b''v''+\text{\&c.} \qquad (3)\\ \zeta&=cv+c'v'+c''v''+\text{\&c.}\end{aligned}$$

On substituting in these equations the values of v, v', v'', &c. given by the equations (1), there results

$$\begin{aligned} \xi&=\mathrm{S}(al)+x\mathrm{S}(aa)+y\mathrm{S}(ab)+z\mathrm{S}(ac)+\text{\&c.}\\ \eta&=\mathrm{S}(bl)+x\mathrm{S}(ab)+y\mathrm{S}(bb)+z\mathrm{S}(bc)+\text{\&c.} \qquad (4)\\ \zeta&=\mathrm{S}(cl)+x\mathrm{S}(ac)+y\mathrm{S}(bc)+z\mathrm{S}(cc)+\text{\&c.}\end{aligned}$$

a system of equations equal in number to the number of elements x, y, z, &c. and from which, consequently, those elements would be determined absolutely if the observations were perfectly exact, that is, if the errrors v, v', v'', &c. were individually zero, and consequently ξ, η, ζ, &c., were each zero. On eliminating y, z, &c. from the last system, the value of x is given in terms of ξ, η, ζ, and known quantities by a linear equation of the following form:

$$x=\mathrm{A}+f\xi+g\eta+h\zeta+\text{\&c.} \qquad (5)$$

where f, g, h, &c. are co-efficients independent of x, y, z, &c. and also of ξ, η, ζ, &c.

If we now substitute in equation (5) the values ξ, η, ζ, &c. given by equations (3), and also assume

$$\begin{aligned} a&=fa+gb+hc+\text{\&c.}\\ a'&=f'a'+g'b'+h'c'+\text{\&c.} \qquad (6)\\ a''&=f''a''+g''b''+h''c''+\text{\&c.},\end{aligned}$$

we shall have by addition

$$x=\mathrm{A}+av+a'v'+a''v''+\text{\&c.};$$

whence it appears that a, a', a'', &c. are a system of multipliers by which y, z, &c. are eliminated from equations (1); they must therefore satisfy the equations (2), whence

$$\begin{aligned} &aa+a'a'+a''a''+\text{\&c.}=1\\ &ab+a'b'+a''b''+\text{\&c.}=0 \qquad (7)\\ &ac+a'c'+a''c''+\text{\&c.}=0.\end{aligned}$$

Subtracting these from the equations (2) we obtain

$$\begin{aligned} 0&=(k-a)a+(k'-a')a'+(k''-a'')a''+\text{\&c.}\\ 0&=(k-a)b+(k-a)b'+(k''-a'')b''+\text{\&c.}\\ 0&=(k-a)c+(k-a)c'+(k''-a'')c''+\text{\&c.},\end{aligned}$$

on multiplying which respectively by f, g, h, and adding the products, we get by reason of the equations (6),

$$0=(k-a)a+(k'-a')a'+(k''-a'')a''+\text{\&c.}$$

This equation may be put under the form $k^2+k'^2+k''^2+$&c.

$$=\alpha^2+\alpha'^2+\alpha''^2+\text{\&c.}+(k-\alpha)^2+(k'-\alpha')^2+(k''-\alpha'')^2+\text{\&c.}$$

from which it is evident that $k^2+k'^2+k''^2+$ &c. will be a minimum when $k=a$, $k'=a'$, $k''=a''$, &c. Hence it follows that the most probable value of x which can be deduced from the equations (1), is $x=\mathrm{A}$; and by (150) the weight of the determination is $1\div(aa+a'a'+a''a''+\text{\&c.})=1\div\mathrm{S}(aa)$.

This quantity $\mathrm{S}\,(aa)$ is equal to f the co-efficient of ξ in the equation (5); for on multiplying the first of equations (7), by f, the second by g, and the third by h, and adding the products, we obtain by reason of equations (6),

$$aa+a'a'+a''a''+\text{\&c.}=f.$$

157. The method explained in the two last paragraphs of determining the most advantageous combination of a system of linear equations, of the form of those in (154), is given by Gauss in his *Theoria Combinationis Observationum erroribus minimis obnoxiæ*, (Gottingen, 1823). The practical rule to which it leads is as follows: Having given a near value V of a function of several elements, X, Y, Z, &c. and also a series L, L′, L″, &c. of observed values of V, make $(\mathrm{V}-\mathrm{L})\sqrt{w}=v$, $(\mathrm{V}-\mathrm{L}')\sqrt{w'}=v'$, $(\mathrm{V}-\mathrm{L}'')\sqrt{w'}$, $=v''$, &c. and form the equations in (1). From these equations (4) are easily deduced; and from these, again, by elimination, are found the values of x, y, z, &c. the corrections of the approximate elements X, Y, Z, &c., in equations of the form (5), which, for the sake of symmetry, may be thus written:

$$\begin{aligned} x&=\mathrm{A}+(\alpha\alpha)\xi+(\alpha\beta)\eta+(\alpha\gamma)\zeta+\text{\&c.}\\ y&=\mathrm{B}+(\alpha\beta)\xi+(\beta\beta)\eta+(\beta\gamma)\zeta+\text{\&c.}\\ z&=\mathrm{C}+(\alpha\gamma)\xi+(\beta\gamma)\eta+(\gamma\gamma)\zeta+\text{\&c.}\end{aligned}$$

then the most probable values of x, y, z, &c. are repectively A, B, C, &c.; the weights of the determinations respectively $\dfrac{1}{(\alpha\alpha)}$, $\dfrac{1}{(\beta\beta)}$, $\dfrac{1}{(\gamma\gamma)}$, &c.; and the probable errors of the several determinations are $\rho\sqrt{(\alpha\alpha)}$, $\rho\sqrt{(\beta\beta)}$, $\rho\sqrt{(\gamma\gamma)}$, &c., where $\rho=\cdot476936$.

158. The values of x, y, z, &c. now deduced are obtained immediately, by supposing the sum of the squares of the errors of observation to be a minimum. Thus, forming the squares of the equations (1), and making $\Omega=v^2+v'^2+v''^2+$ &c., the differentiation of Ω in respect of each of the variables x, y, z, &c. produces the quantities denoted in (156), by ξ, η, ζ, &c. that is to say, it gives

$$\frac{d\Omega}{dx}=2\xi,\ \frac{d\Omega}{dy}=2\eta,\ \frac{d\Omega}{dz}=2\zeta, \text{ \&c.}$$

therefore if Ω be a minimum, ξ, η, ζ, become severally zero, and the equations (4) give by elimination, $x=\mathrm{A}$, $y=\mathrm{B}$, $z=\mathrm{C}$, where A, B, and C denote the same quantities as above. Now from equation (5) the general value of x is

$$x=\mathrm{A}+(\alpha\alpha)\xi+(\alpha\beta)\eta+(\alpha\gamma)\zeta,$$

and the most probable value being $x=A$, it follows that the most probable values of the corrections x, y, z, are found by making the differential coefficients of Ω equal to zero, that is, by making $v^2+v'^2+v''^2+$ &c. an absolute minimum. Hence this method of combining equations of condition is called the *method of least squares;* and it follows from the preceding analysis, that it gives the most probable values of the corrections, or the most advantageous results.

159. As an example, let us suppose there is only one unknown element X, of which X_o is known to be an approximate value, and L, L′, L″, &c. are observed values, the weights of which are respectively proportional to w, w', w'', &c. and that it is required to determine the most probable value of X from the observations, and also the weight of the determination. Make $(X-L)\sqrt{w}=v$, $(X_o-L)\sqrt{w}=l$, and let x be the correction of X, so that $X=X_o-x$. On substituting this in $(X-L)\sqrt{w}=v$, we have $(X_o-x-L)\sqrt{w}=v$, or $v=l\sqrt{w}-x\sqrt{w}$. Each observation gives a similar equation, and the equations (1) in (154) consequently become

$$v=l\sqrt{w}-x\sqrt{w}$$
$$v'=l'\sqrt{w'}-x\sqrt{w'}$$
$$v''=l''\sqrt{w''}-x\sqrt{w''}, \text{ \&c.}$$

therefore, multiplying each by the coefficient of its own x, we have $\xi=S(lw)-xS(w)$, whence consequently $x=S(lw)\div S(w)-\xi\div S(w)$, that is to say, the most probable value of x is

$$x=\frac{lw+l'w'+l''w''+\text{ \&c.}}{w+w'+w''+\text{ \&c.}},$$

and the weight of the determination is proportional to the reciprocal of $w+w'+w''+$ &c.

Since $X-L=x-l$, we have also

$$X=\frac{Lw+L'w+L''w+\text{ \&c.}}{w+w'+w''+\text{ \&c.}},$$

whence this proposition: If a series of values of an element are found from observations which have not all the same degree of precision, the most probable value of the element is found by multiplying each observation by a number proportional to its weight, and dividing the sum of the products by the sum of the weights; and the comparative weight of the result is unit divided by the sum of all the weights.

If the weights be all equal, and the number of the observations be h, then $X=(L+L'+L''+\text{ \&c.})\div h$; that is to say, the average of a series of equally good observations gives the most probable value. The average may, therefore be considered as a particular case of the method of least squares.

160. To illustrate the method of proceeding when there are several elements to be corrected from the observations, we shall take the following numerical example from Gauss (*Theoria Motus*). Suppose there are three elements, and that three observations, of equal weight, have given the equations $x-y+2z=3$, $3x+2y-5z=5$, $4x+y+4z=21$; and that a fourth observation, of which the relative weight is one-fourth, or its precision one-half, of that of the others has given $-2x+6y+6z=28$. The first step is to reduce this last equation to the same standard of weight with the others, for which purpose it must be multiplied by $\frac{1}{2}$; it then becomes $-x+3y+3z=14$. Now, as x, y, and z cannot be determined so as to satisfy four independent equations, we suppose each observation, or equation, to be affected with an error v, and accordingly obtain the following system of equations, corresponding to equations (1), viz.:

$$v=-3+x-y+2z$$
$$v'=-5+3x+2y-5z$$
$$v''=-21+4x+y+4z$$
$$v'''=-14-x+37+3z,$$

from which the most probable values of x, y, and z are to be deduced. Let each equation be multiplied by the coefficient of its own x, taken with its proper sign, namely, the first by 1, the second by 3, the third by 4, and the fourth by -1; the results added together give the value of ξ, namely, $\xi=-88+27x+6y$. In like manner, let the first be multiplied by -1, the second by 2, the third by 1, and the fourth by 3, the sum of the products will give η. Lastly, let the equations be multiplied respectively by the coefficients of z, and the sum of the products made equal to ζ; we have then the following equations corresponding to the equations (4)

$$\xi=-88+27x+6y+0$$
$$\eta=-70+6x+15y+z$$
$$\zeta=-107+0+y+54z.$$

From these we get by elimination

$$19899x=49154+809\xi-324\eta+6\zeta$$
$$737y=2617-12\xi+54\eta-\zeta$$
$$39798z=76242+12\xi-54\eta+1473\zeta,$$

whence (157) A, B, C, the most probable values of x, y, z, are respectively

$$A=\frac{49154}{19899}=2{\cdot}470,\ B=\frac{2617}{737}=3{\cdot}551,\ C=\frac{76242}{39798}=1{\cdot}916;$$

and the relative weights w, w', w'', are respectively

$$w=\frac{19899}{809}=24{\cdot}6,\ w'=\frac{737}{54}=13{\cdot}6,\ w''=\frac{39798}{1473}=27{\cdot}0,$$

whence the probable errors $({\cdot}476936\div\sqrt{w})$ are respectively ·096, ·129, ·092.

The method of least squares, to which modern astronomy is indebted for much of its precision, was first proposed by Legendre, in his *Nouvelles Méthodes pour la Determination des Orbites des Comètes*, (Paris, 1806,) merely as means of avoiding inconvenience and uncertainty arising from the want of a uniform and determinate method of combining numerous equations of condition, and without reference to the theory of probability. The same method, however, had previously been discovered by Gauss, and a demonstration of it, deduced from the general theory of chances, was given by him in his *Theoria Motus*, (1809.) It may be shewn in various ways, that this method of combination gives values of the unknown quantities affected with the smallest probable errors; but it is to be observed, that all the demonstrations are subordinate to the hypothesis, that positive and negative errors of equal magnitude are equally probable, or that the average of a large number of results gives the most probable value, and consequently that the function which represents the probability of an error has the form assigned to it in (132).

The limits of this article will not permit us to enter into further details respecting the applications of the method of least squares. On the general theory of the probable errors of results deduced from observation, and the most advantageous methods of combining equations of condition, the reader may consult the *Théorie Analytique des Probabilités* of Laplace; the *Theoria Motus* of Gauss; the *Theoria Combinationis Observationum*, and the *Supplementum Theoriæ Combinationis*, &c. (Göttingen, 1828) of the same author; the *Recherches sur la Probabilité des Jugements*, with the two Memoirs of Poisson in the *Connaissance des Tems* for 1827 and 1832; and three masterly papers, by Mr Ivory, in the *Philosophical Magazine* for 1825. In the volumes of the *Berliner Astronomisches Jahrbuch* for 1833, 1834, and 1835, M. Encke has treated the subject at great length, and given a number of formulæ calculated to facilitate the labours of the computer. We may also refer, in conclusion, to a remarkable disquisition on the theory of probable errors, by the celebrated astronomer Bessel, forming Nos. 358 and 359 of Schumacher's *Astronomische Abhandlungen*, Altona, October 1838.

(T. G.)

TABLE of the Values of the Integral $\Theta = \frac{2}{\sqrt{\pi}}\int_0^{\tau} e^{-t^2}dt = 1 - \frac{2}{\sqrt{\pi}}\int_{\tau}^{\infty} e^{-t^2}dt$, for intervals each =·01, from $\tau=0$ to $\tau=3$, with their first and second differences.

PROBATE of a will or testament, in law, is the exhibiting and proving of last wills and testaments before the ecclesiastical judge delegated by the bishop, who is ordinary of the place where the party died.

PROBLEM (πρόβλημα, from προβάλλω, *I put forward*), a question proposed. In logic, a proposition that appears neither absolutely true nor absolutely false; and consequently may be asserted either in the affirmative or negative. In geometry, a proposition in which some operation or construction is required; as to divide a line or an angle, let fall a perpendicular, &c. In general, any question involving doubt or uncertainty, and requiring further evidence for its solution.

PROBUS, MARCUS AURELIUS, a Roman emperor, was born at Sirmium in Pannonia, and entered the army at a very early age. His rise to eminence was brilliant and rapid. While he was still a mere boy, the Emperor Valerian made him a military tribune, and placed him on the ladder of promotion. As he rose in fortune, he increased in ability. His considerate bearing and judicious discipline won the hearts of his subordinates, and his upright character and professional skill secured the esteem of his superiors. There was not a military duty which this admirable youth did not perform in a manner which demanded the greatest rewards and challenged the highest praise. His personal valour on the field gained bracelets, spears, the mural and civic crowns, and other badges of soldierly merit. His campaigns in Africa, Egypt, Arabia, Scythia, Persia, Germany, and Gaul, raised him high in the estimation of several successive emperors. In the reign of Tacitus especially he was greatly in favour, and was appointed commander-in-chief of all the eastern provinces. At length, on the death of that emperor in 276, he was brought forward as a candidate for the purple; his rival, Florianus, soon fell before him, and he was declared emperor with the united consent of the army, the people, and the Senate.

An arduous task now lay before Probus. He set himself with all his characteristic energy and rapidity to reform and consolidate the empire, which was distracted by discordant elements from within, and impaired by hostile agencies from without. His first measure was to establish peace throughout his dominions. Placing himself at the head of a mighty army, and advancing eastward from the coasts of Gaul, he began to overwhelm all opposition with one sweeping campaign. No foe could resist his impetuous onward march. The barbarian invaders of the Gallic province were cut to pieces before his terrific onslaught, and fled across the borders, leaving 400,000 slain. The enemies beyond the Rhine, catching the rumours of his triumphs as he advanced across the continent, became paralysed with fear. Nine of the most powerful German princes threw themselves down at his feet, and submitted to be hemmed in within their own territories by a line of posts. The power of the vagrant Sarmatians was shattered before him; the Goths upon the Thracian borders were awed into submission; and no hostile tribe was left unsubdued in the whole of Europe. No sooner had that campaign been completed than he hastened to Asia Minor to storm the robber Isaurians in their mountain fastnesses. A long time had not elapsed before he was in Ethiopia, suppressing the rebellion of the savage Blemmyes. He then repaired to Alexandria, and checked the revolt of his own general Saturninus. At length he brought his wars to a conclusion in 280, by quelling the mutiny of his two officers Bonosus and Proculus in Gaul. After Probus had thus effected peace, his next design was to strengthen it by promoting industry. Accordingly a vigorous system of policy was set on foot to encourage honest labour. Predatory tribes were removed into the heart of strange countries, where circumstances might compel them to lay aside their warlike habits, and to have recourse to peaceful pursuits. Lands, cattle, and implements were also given to those who were inclined to follow husbandry. Nor were these measures tried upon civilians alone. The soldiers likewise were subjected to toil, in order that they might preserve their hardihood and discipline. The whole empire in fact seemed to be acquiring internal prosperity when an event occurred which removed the originator and administrator of this peaceful policy. It happened on a broiling August day of 282, that Probus stood urging on the soldiers while they were engaged in the unhealthy and toilsome task of draining the marshes of Sirmium. The drudgery of the work and his severe exactions threw the sweating troops into a ferment of discontent and indignation. All at once they flung down their ignoble tools, seized their warlike weapons, and rose in one wild mass of confusion and mutiny. It was to no purpose that the emperor took refuge in a strong tower. The fury of his soldiers was irresistible; the tower was forced, and a thousand swords were plunged into his body.

PROCACCINI, a family of eminent Italian artists, of whom ERCOLE PROCACCINI was the father. He was born at Bologna in 1720, and practised his profession at Milan. Laborious, careful, and exact, he did not fail to achieve success. His pictures, in spite of a tameness of colouring and an over-minuteness of detail, were notable for their graceful and correct figures, and their freedom from slovenly mannerisms. His mode of teaching was especially painstaking and excellent. Some of the most distinguished artists of the Milanese school issued from his academy. Ercole Procaccini was still living in 1591. His principal works are in the churches of Bologna.

PROCACCINI, *Camillo*, the eldest son of the preceding, was born at Bologna in 1546. The course of training by which he was fitted for his profession was very thorough. In his father's school he was inured to patient and tasteful elaboration. Then repairing to Rome to complete his education for himself, he acquired higher qualifications. The contemplation of the great creations of Michael Angelo kindled his imagination. The study of the graceful heads of Parmigiano refined his taste. His brain became ready and fertile in inventing, and his hand became rapid and felicitous in executing. There was scarcely an artistic accomplishment, in fact, which he did not easily acquire. Camillo Procaccini thus attained to great eminence, and his name became well known in many cities. At Bologna, Ravenna, Pavia, and Genoa, he received as much employment as would have occupied two artists. At Reggio he painted "St Rocco Dispensing the Sacrament to the Plague-stricken Victims" with so much excellence that Annibale Caracci was discouraged when he was commissioned to execute a companion picture to it. At Piacenza he finished a fresco of the "Coronation of the Virgin," which was only eclipsed by an adjacent work of his great rival above mentioned. Nor was his fame less at Milan, his fixed place of residence. At the time of his death in 1626 there were few artists who rivalled him in the estimation of his fellow-citizens.

PROCACCINI, *Giulio Cesare*, was the second son of Ercole Procaccini, and was born at Bologna in 1548. He was studying sculpture when the success of his brother Camillo induced him to enter upon the profession of a painter. The excellence which he soon attained in his new profession was very great. His conceptions were multiform and grand, his design was dignified and correct, and his colouring was rich and harmonious. Pervading all there was an exquisite grace, which was evidently copied from Corregio, and which approached nearer to the style of that great master than any imitations had ever done before. Such a number of estimable accomplishments could not fail to secure for Procaccini an honourable place in the annals of painting. Accordingly, at his death in 1626 he left several pictures which still preserve a high reputation. The most famous of these are at Milan. There are a "Deposition" and the "Martyrdom of St Nazarus and St Celsus" in the church of La Madonna, a "St Carlo" in the church of San Tomaso in Terra Mala, an "Annunciation" and several other pictures in the church of San Antonio, a portrait of Pope Julius III. in the imperial palace, and the "Adoration of the Magi" in the Brera gallery.

PROCACCINI, *Carlo Antonio*, was the third son of Ercole Procaccini, and was born at Bologna in 1555. Although brought up in the school of his father, he spent his life chiefly in painting landscapes, flowers, and fruits. He had a son named Ercole who obtained some repute as an artist.

PROCIDA, GIOVANNI DI, an eminent Sicilian patriot, was born at Salerno about 1225, and became proprietor of the island of Procida. His first appearance on the stage of history was made in 1266, when Charles of Anjou slew Manfredi, King of Sicily, at the battle of Benevento, and seized upon the vacant throne. All his time and fortune were forthwith staked upon an enterprise for restoring the expelled house of Hohenstauffen. To draw the sword in behalf of the stripling Conrad was his first attempt. When that prince was defeated and executed, all his efforts were next directed to the formation of a widely-organized conspiracy against the triumphant usurper. He hastened to Spain to persuade Peter of Aragon to claim the Sicilian crown in right of his wife, the daughter of Manfredi. He returned to Sicily in disguise, to encourage the rebellious spirit among his countrymen, with the promise of assistance from the King of Aragon. He then repaired to the Emperor Michael Palæologus at Constantinople, and brought back money to buy weapons for the disarmed natives. At length he drew the chief of his accomplices to Palermo, and waited until some accident should light the train which he had so artfully laid. That accident soon occurred. It happened on the Easter Monday of 1282 that a mixed procession of citizens and French invaders set out from Palermo to hear vespers at a neighbouring village church. On the way a Frenchman began to be rude to a Sicilian maiden, and was immediately stabbed to the heart by the betrothed of the insulted girl. This desperate deed acted like a firebrand upon the excited tempers of the natives. Their long pent-up revenge burst into a wild explosion; the cry of "Death to the French" rose in the air; each man turned with drawn dagger upon the foreigner that was next him; and before the vesper-bell had ceased to sound, every Frenchman in the company was slain. Nor was their thirst for vengeance slaked with so much blood. They rushed home to exterminate those foreigners who had remained in the city. Neither age nor sex was spared. The carnage raged indiscriminately until 4000 lay weltering in their blood, and the fury of the assassins was suddenly checked for want of victims. This massacre, known by the name of "the Sicilian vespers," decided the fate of Sicily. The revolt spread through the rest of the country; Peter of Aragon landed and received the crown; Charles of Anjou was repulsed in his attempt to regain the island; and Giovanni di Procida, before his death at the beginning of the fourteenth century, had the satisfaction of seeing that through his patriotic exertions the lawful sovereigns of Sicily were seated in undisputed possession of the throne.

PROCIDA (anc. *Prochyta*), an island in the Mediterranean, belonging to the kingdom of Naples, lies between Cape Miseno and the island of Ischia, at the northern extremity of the Bay of Naples. Its form is irregular; and it is 2½ miles from N.E. to S.W., and as much from N.W. to S.E. A strait, 3½ miles broad, separates it from the mainland. The northern extremity of the island terminates in steep and picturesque cliffs; on one of which, Cape Rocciola, the N.E. point, stands a ruined castle commanding a fine view. On the slopes of this hill, towards the south, the town of Procida, with its flat-roofed houses, gardens, vineyards, and orange groves, has a beautiful appearance. Its population is 3400. The island is chiefly occupied with gardens and vineyards; and the people are employed in these and in seafaring pursuits, which are actively carried on,—no fewer than 300 vessels being owned in the island. The chief article of commerce is fruit. The inhabitants are of Greek origin, retaining the costume, and, on festive occasions, performing the characteristic dances of that nation. Procida now belongs to the crown, though it was at one time the property of a family, of which John of Procida, the author of the Sicilian Vespers, was the most famous member. Pop. 14,580.

PROCLAMATION, a public notice given of anything of which the sovereign thinks proper to advertise his subjects. Proclamations form a branch of the sovereign's prerogative, and they have a binding force when they are grounded upon and enforce the laws of the realm. For, though the making of laws is entirely the work of the legislative branch of the sovereign power, yet the manner, time, and circumstances of putting those laws into execution must frequently be left to the discretion of the executive magistrate; and therefore his *proclamations* are binding upon the subject, where they do not either contradict the old laws or tend to establish new ones, but only enforce the execution of such laws as are already in existence, in such manner as the sovereign shall judge necessary.

PROCLUS, surnamed "the Successor" (Διάδοχος), either from his being the successor of Syrianus in the direction of the Athenian school, or, which is much more probable, from his being regarded as the genuine successor of Plato, was the last and one of the most celebrated of the Neo-Platonists. He was born at Byzantium on the 8th of February, A.D. 412, though, as the son of the Lycian Patricius, he frequently regarded himself as a native of Xanthus, where the earlier part of his life was spent. From Xanthus he removed to Alexandria while still young, and was received into the family of Leonas the rhetorician, who introduced him to the leading scholars of the city. Purposing to pursue the study of jurisprudence, he studied grammar under Orion, and applied himself to the Latin tongue. Having visited Byzantium in the company of Leonas, he, immediately on his return, abandoned rhetoric and law for the study of philosophy, and sought the instructions of Olympiodorus. This choice of a teacher, while it could not have been called a happy one for an ordinary man, was eminently so for Proclus. The apparent obscurity of his master, his penetrating intellect rendered luminous; and what he could not fully understand on its delivery, he was enabled to preserve for future study by his prodigious memory. His master was charmed with his genius; so also was his master's daughter; whether or not for his talents, does not appear. Leaving Alexandria at the age of twenty, he chose Athens for a residence. He had the good fortune to make the acquaintance of Plutarchus, the son of Nestorius, who read with him the *De Anima* of Aristotle and the *Phædo* of Plato. On his death, Plutarchus commended him to the care of Syrianus, who employed him as his coadjutor. So great was his industry and so intense his application, that by his twenty-eighth year he had written his commentary on the *Timæus* of Plato. He succeeded Syrianus at his death, continued his school, and seems to have realized a handsome income from the undertaking. From whatever cause, he was compelled to quit Athens for a year, which afforded him leisure to visit the East, and compile a collection of Chaldæan oracles. He opened school on his return; and seems to have disclosed the profounder principles of his philosophy only to his confidential disciples, on whom secrecy was enjoined. In his religious ceremonies he observed a like strictness. He was possessed of great strength and remarkable personal beauty, which numerous matrimonial proposals still attest; but his adherence to fasts and vigils, to labour and asceticism, led him to decline such connections, and bestow his friendship upon Archiadas and others of his disciples. Of his theurgic knowledge and discipline let nothing be said. The reader will find much of that and other absurd matters in the *Vita Procli* of Marinus. Proclus died on the 17th of April 485 A.D.

Twenty-two works or pieces of Proclus are still extant. There is no complete edition of them. That of Cousin (Paris, 6 vols. 8vo, 1820–27) contains the treatises on Providence and Fate, on the Ten Doubts about Providence, and on the Nature of Evil; the Commentary on the Alcibiades, and the Commentary on the Parmenides. The following have been translated into English by Thomas Taylor:—The Commentaries on the Timæus, the six books on the Theology of Plato, the Commentaries on the first book of Euclid, the Theological Elements, the five Hymns, and his Life by Marinus. Besides the works already mentioned, seventeen others have unfortunately perished. Proclus regarded the Orphic and Chaldæan oracles as divine revelations, capable of an allegorical interpretation, whereby he endeavoured to make Plato and Aristotle agree. He elevated faith (πίστις) above science; and strove to demonstrate that there is but one real principle of things—viz., *Unity*, which by its own development produces all things by triads. These triads he considered to be Unity, Duality, which is identical with limitation and boundlessness, and the complex of both, which contains Esse, Life, and Intelligence, the three fundamental dispositions of things. The Divinities he distinguished into Intelligible and Intelligent, Supernatural and Natural. He exalted Theurgy above Philosophy, attributed a supernatural efficacy to the name of the Supreme Being, and was hostile to the Christian religion.

PROCONSUL, a Roman magistrate sent to govern a province with consular authority. The proconsuls were appointed out of the body of the Senate; and commonly, when the year of any one's consulate expired, he was sent as proconsul into some province. The proconsuls decided cases of equity and justice, either privately in their palace, where they received petitions, heard complaints, and granted writs under their seal; or publicly, in the common hall, with the usual formalities observed in the court of judicature at Rome. Their office lasted only a year.

PROCOPIUS, an eminent Byzantine historian, was a native of Cæsarea in Palestine, where he was born in the beginning of the sixth century after Christ. He removed to Constantinople while still young, and rose to great distinction as an advocate and professor of eloquence. He attracted the attention of Belisarius, who in 527 A.D. chose him for his secretary. He accompanied the hero on his different wars in Asia, Africa, and Italy; and in the Gothic expedition he was placed at the head of the Byzantine navy. On his return to Constantinople, his merits were appreciated by the Emperor Justinian, who conferred upon him the title of *illustris*, chose him a senator, and made him prefect of the city in 562 A.D. Procopius died about 565 A.D.

It is a matter of question whether Procopius was a Christian or an adherent of paganism. His chief works are his Ἱστορίαι, in eight books; his Κτίσματα, in six books, which flatters Justinian immoderately; his Ἀνέκδοτα, a *chronique scandaleuse* of the court of Constantinople from A.D. 549 till 562; and his *Orationes*, consisting probably of extracts from his *History*. The works of Procopius have been published in the Bonn collection of the Byzantines, with a carefully-revised text and a Latin version, by Dindorf, 3 vols. 8vo, 1833–38. The *History* has been rendered into nearly all the modern languages of Europe. It was translated into English by Sir Henry Holcroft, Lond. 1653. His *Anecdotes* was likewise translated into English by an anonymous author, under the title of *The Secret History of the Court of the Emperor Justinian*, London, 1674.

PROCRUSTES (Προκρούστης, *the stretcher*), is a surname of the celebrated robber Polypemon or Damastes, who tortured his victims by placing them on an iron bed, which their stature was made to fit by stretching or mutilation. Hence the well-known proverb "the bed of Procrustes." He was slain by Theseus on the Cephissus in Attica.

PROCTOR, a person commissioned to manage another person's cause in any court of the civil or ecclesiastical law.

PROCTOR. See UNIVERSITIES.

PROCURATOR-FISCAL, the public prosecutor in inferior courts in Scotland acting under the instructions of the lord advocate, who is the principal public prosecutor. The procurator-fiscal usually makes the preliminary inquiries as to crimes committed in his district; and transmitting the papers to the lord advocate, that officer, or one of his assistants, either directs the case to be prosecuted at his own instance before the superior court, or leaves it to the conduct of the procurator-fiscal in the inferior court.

PRODICUS, a celebrated sophist, was a native of Iulis in the island of Ceos, and flourished about B.C. 432. He was the contemporary of Democritus of Abdera and Gorgias of Leontium, and he was the disciple of Protagoras, whom he rivalled in eloquence. His talents were so highly appreciated by his fellow-citizens that he was employed on various embassies, and on his arrival at Athens he opened a school, where he was attended by the most distinguished men of the age—Euripides, Socrates, Theramenes, and Isocrates. Xenophon has preserved an apologue of Prodicus (Mem. ii. 1), which is considered as one of the most precious fragments of antiquity; it is known as the "Choice of Hercules." In the *Axiochus* of Plato there is also the analysis of a harangue which Prodicus composed to dissipate all fears of death. According to Suidas, he was at last accused of being a corrupter of youth, and condemned to drink hemlock.

PROFESSOR. See UNIVERSITIES.

PROGRAMME (πρόγραμμα, *a public proclamation*), is an old university term applied to an outline of the orations to be delivered on a particular occasion; but now used in a more extended signification to denote the outline of any entertainment or public ceremony.

PROGRESSION, in mathematics, is either arithmetical, geometrical, or harmonical. Continued arithmetical proportion is, where the terms increase and decrease by equal differences, and is called *arithmetical progression*, thus:—

Increasing, 1, 3, 5, 7, 9, &c.
Decreasing, 18, 15, 12, 9, 6, &c.

Geometrical progression is when the terms increase or decrease by equal ratios, thus:—

Increasing, 1, 2, 4, 8, 16, &c.
Decreasing, 81, 27, 9, 3, 1, &c.

An *harmonical progression* is such, that of any three consecutive terms, the first is to the third as the difference between the first and second is to the difference between the second and third. The reciprocals of the arithmetical series, 1, 2, 3, 4, 5, &c., are $\frac{1}{1}$, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c., which forms an harmonical progression.

PROJECTILES. See GUNNERY.

PROJECTION OF THE SPHERE. See GEOGRAPHY, *Mathematical*.

PROJECTION. See PERSPECTIVE.

PROLATION, a musical term signifying a series of notes, ascending or descending, which are to be sung to one syllable. Anciently the word had a different musical meaning. Thus Morley, in his *Introduction*, page 14, tells us that prolation is the measuring of semibreves by minims, and is either greater or less. The greater prolation is when the semibreve contains three minims. The sign of this is ⊙ or Ͼ. The less prolation is when the semibreve contains only two minims. The sign of this is ○ or C. The old musicians called the ternary measure *perfect*, and the binary measure *imperfect*. (G. F. G.)

PROLEGOMENA, certain preparatory observations prefixed to a book or treatise, and containing something necessary for the reader to be apprised of, to enable him the better to understand the book, or to enter deeper into the science.

PROLOGUE (πρόλογος), in the Greek tragedy, a word employed to designate the introduction to the spectator of the subject of the drama, whether tragedy or comedy. The desired information could be communicated either indirectly in the course of the action itself, or by a direct account given to the audience. The former method being the more agreeable to probability, was that adopted by Æschylus and Sophocles, the latter by Euripides. In the Latin comedy the prologue (*prologus*) was an address of the poet to the audience. The modern prologue is a short discourse addressed to the audience, to inform them of the subject of the piece, and not unfrequently to apologise for the poet. It is generally neither composed nor spoken by the author of the drama.

PROME (called by the Burmese *Pri*, and by the Mohammedans *Pron*), a town in the British territory of Pegu, on the left bank of the Irrawaddy, 113 miles N.W. of Pegu. It is surrounded by a brick wall, palisade, and ditch, about two miles in circuit, and outside of these there are extensive suburbs. South of the town stand many pagodas, on the tops of small but steep hills. The flatness of the ground on which it is built renders the town liable to inundations of the river; and it has also on more than one occasion suffered from fire. By the latter calamity nearly the whole town was destroyed in the beginning of 1856. It has, however, many advantages for its speedy rise, especially as a place of trade. Paper is made here; and the adjacent country is laid out in gardens and rice-grounds. The town was taken by the British in 1825, and again in 1852, on both occasions with hardly any opposition from the Burmese. Pop. 30,000.

PROMETHEUS, the son of Iapetus and Clymene, was the brother of Atlas, Epimetheus, and Menœtius. He was a prince of Mecone (the ancient name of Sicyon in the Peloponnesus), if we may trust the legend told by Hesiod. It is said that the inhabitants were debating with the gods which part of the animal ought to be offered to them in sacrifice, and that Prometheus recommended that the flesh and best parts should be covered with the caul, whilst the bones were enveloped in fat. Jupiter was then requested to make choice of the part he preferred; and, being deceived by the trick of Prometheus, he selected the bones, which were ever afterwards offered upon his altar. Indignant at this proceeding, he deprived men of the use of fire; but Prometheus is said to have again outwitted him, and drawn down fire from heaven, which he presented to man. This is explained by supposing that Prometheus was the first who discovered that fire could be extracted from two pieces of wood rubbed together. By another tradition, we find him making a man of clay, into which he conveys the fire he had stolen from heaven, and for this daring invasion of his privileges Jupiter orders Vulcan to chain Prometheus on Mount Caucasus, where he was visited daily by an eagle, which fed on his liver. Here he is said to have remained thirty thousand years, until Hercules accidentally visited him whilst in search of the gardens of the Hesperides. Prometheus pointed out the way to him, and from gratitude Hercules slew the eagle and released Prometheus. Another tradition represents him as having been released by Jupiter, in return for warning him against marrying Thetis, as it was fated that her son should be more illustrious than his father. He was the father of Deucalion by Clymene or Pandora. (See PANDORA.) There is a very sound explanation of the mythus of Prometheus, as given by Æschylus, in the *Classical Museum*, vol. v., by Professor Blackie of Edinburgh.

PROMONTORY, a point of land or rock projecting into the sea, the extremity of which is called a *cape* or *headland*. (See GEOGRAPHY.)

PROMPTER, in the drama, an officer posted behind the scenes, whose business it is to watch attentively the actors speaking on the stage, in order to suggest and aid them when at a stand, and correct them when at fault.

PRONAOS. See *Glossary* to ARCHITECTURE.

PRONOUN. See GRAMMAR.

PRONY, GASPARD-CLAIR-FRANÇOIS-MARIE-RICHE DE, a celebrated French engineer, was born at Chamelet, in the department of the Rhone, in 1755, and was educated at the École des Ponts et Chaussées. An essay on the *Thrust of Arches*, published in 1783, was the means of introducing him to a long course of public employment. He was engaged under Peronnet in restoring the fort of Dunkirk in 1785, and in erecting the bridge of Louis XVI. in 1787. The laborious enterprise of drawing up the famous *Tables du Cadastre* was entrusted to his direction in 1792. In 1794 he was charged with the professorship of mechanics in the École Polytechnique, and in 1798 he was appointed Directeur-General des Ponts et Chaussées. His success continued after the overthrow of the republic and the establishment of the empire. He was employed by Napoleon to superintend the engineering operations both for protecting the province of Ferrara against the inundations of the Po, and for draining and improving the Pontine Marshes. He was likewise engaged after the restoration in regulating the course of the Rhone, and in several other important works. By the accomplishment of so many laborious undertakings, Prony had gained a high place in the estimation of the patrons of science. The title of baron was conferred upon him in 1828, and that of peer in 1835. He was also, at the time of his death in 1839, a member of the principal academies and scientific societies of Europe.

Among the numerous publications of Prony are the following:—*Nouvelle Architecture Hydraulique*, in 2 vols., 1790–96; *Mécanique Philosophique*, in 4to, 1800; *Analyse de l'Exposition du Système du Monde par Laplace*, in 8vo, 1801; *Recherches sur la Poussée des Terres*, in 4to, 1802; *Recherches Physico-Mécaniques sur la Théorie des Eaux Courantes*, in 4to, 1804; *Cours de Mécanique Concernunt les Corps Solides*, in 2 vols. 4to, 1815; and *Description Hydrographique et Historique des Marais Pontins*, in 4to, 1822–23.

PROOF. See EVIDENCE, and LOGIC.

PROPERTIUS, SEXTUS AURELIUS, a celebrated elegiac poet, who flourished between 31–15 B.C. The exact date of his birth is uncertain; but Clinton brings forward satisfactory reasons for believing that it was about the year 51 B.C., being thus fourteen years younger than Horace, and eight younger than Livy. The place of his birth has also been disputed; but he himself states that he was a native of Umbria, though whether of Mevania, Ameria, Hispellum, or Asisium, is uncertain. He studied at Rome, with the intention of devoting himself to the bar; but his love of poetry seduced him from the dry study of law, and he entirely withdrew from taking any share in the active business of life. He died at an early age, leaving behind him a collection of elegies divided into four books, of which the last is supposed to have been published by one of his friends after his death. Nobbe, a German critic, who has examined the subject with considerable care, thinks that the first book was published not before 29 B.C., and not after 27 B.C.; the second book not before 24 B.C.; the third not before 21 B.C.; the fourth not before 16 B.C.

Many of Propertius's elegies are addressed to his mistress Cynthia, to whom he remains constant, though he suffers much from her cruelty. Her real name was Hostia, and she seems to have belonged to that higher class of courtezans known as ἑταίραι among the Greeks. She herself seems to have been a poetess, besides being skilled in music, dancing, and needlework. The language of his poetry is powerful, and the structure of the verse correct, though not without some peculiarities; as, for example, the close of the pentameter line with a word of several syllables. In comparing the elegies of Propertius with those of Tibullus, we perceive that there is less of tenderness and softness, less of that simplicity for which Tibullus is so eminently distinguished; but, on the other hand, there is more spirit, a greater reach of thought, and more power of expression. He possesses much of the spirit of the lyric poet, and had talents which fitted him for things of greater moment than those upon which he bestowed them. Propertius was a close imitator of the Greek writers; Callimachus and Philetas were the poets whom he more particularly followed, so that he was sometimes called the Roman Callimachus. Like Callimachus, he is fond of displaying his learning, and has frequent allusion to mythological subjects; but this at times is the cause of some obscurity, and detracts from that simplicity which is the soul of true elegiac poetry. One of the best separate editions of Propertius is that of Hertzberg, with a commentary, Halle, 1844–45, 4 thin vols. 8vo, but they are generally published along with Catullus and Tibullus. He has been translated into French, German, and Italian, and into English prose by Gantillon, from the excellent text of Paley. (See Bohn's "Classical Library," 1854.)

PROPERTY (Lat. *proprietas*, ownership), as to its etymology, suggests the notion of a thing being a man's own (*proprius*); a notion, moreover, which is contained in every definition of property. It is defined by a foreign writer as "the right to deal with a corporeal thing according to a man's pleasure, and to the exclusion of all other persons." But this description of property errs by defect, inasmuch as it excludes incorporeal things, which are considered objects of property in English law, and were also regarded as such in Roman law. Property, as here understood, is "that which the positive law of a country recognises as property, and for the protection or recovery of which it gives a remedy, by legal forms, against every person who invades the property or has the possession of it." Property is divided into Things Real and Things Personal. Things Real include lands, tenements, and hereditaments. Hereditaments, again, are divided into Things Corporeal and Incorporeal. The hereditaments, as enumerated by Blackstone (book ii.), are advowsons, tithes, commons, ways, offices, dignities, franchises, corodies or pensions, annuities, and rents. The interest which one has in any land, tenement, or hereditament, is called an estate. (See ESTATE.) Personal property is frequently described by the term "moveables;" but this is inadequate, for certain estates in lands are personal property, and are comprehended under the term Chattels Real. (See CHATTELS.) The legal capacity of persons to transfer and acquire estates in lands and tenements belongs to legal treatises. (*Cyclopædia of Political Knowledge*, 1853; Warren's Blackstone's *Commentaries*, book ii., 1855.)

PROPHECY is a word derived from προφητεία, and in its original import signifies the prediction of future events. As God alone can perceive with certainty the future actions of men and the remote consequences of those laws of nature which he himself established, prophecy, when clearly fulfilled, affords convincing evidence of an intimate and supernatural communion between God and the person who uttered the prediction. (See THEOLOGY.)

PROPONTIS. See MARMORA, *Sea of.*

PROPORTION, the identity or similitude of two ratios. Hence quantities that have the same ratio the one to the other are said to be proportional. Thus, if A be to B as C to D, or 8 be to 4 as 30 to 15, A, B, C, D, and 8, 4, 30, and 15, are said to be in proportion, or are simply called proportionals.

PROPORTION, *Harmonical* or *Musical.* See MUSIC, and TEMPERAMENT.

PROPOSITION. See GEOMETRY.

PROSE, the natural language of mankind, loose and unconfined by poetical measures or restraints; and in this sense it stands opposed to verse or metrical composition.

PROSERPINE, supposed to be derived from φέρειν φόνον, *to cause death*, and is probably corrupted from the Greek, which is variously written Persephone, Phersephassa, Persephassa, Phersephatta, Persephatta, Pherrephassa, Pherephatta, Phersephoncra, and Persephonera. She was the daughter of Jupiter and Ceres, who was carried off by Pluto as she was gathering flowers with her companions. Ceres, disconsolate for the loss of her daughter, after having long sought her, heard where she was, and entreated Jupiter to permit her to return from hell. This request Jupiter granted, on condition that she had not tasted anything in Pluto's dominions. Ceres therefore went to fetch her; but when her daughter was preparing to return, Ascalaphus gave information that he had seen Proserpine eat some grains of a pomegranate she had gathered in Pluto's garden, on which she was sentenced to continue in Tartarus in quality of Pluto's spouse and the queen of those gloomy regions; but, to mitigate the grief of Ceres for her disappointment, Jupiter granted that her daughter should only spend six months in hell together with her husband, and the other six on earth with her mother. Some mythologists imagine that the latter part of the fable alludes to vegetation, which must remain hidden all the winter in order to sprout forth in the spring.

PROSLAMBANOMENOS (Greek προσλαμβανομενος, the term προσλαμβανομενη being found as an exception in Bryennius only) signifies a lower string (χορδη) or sound (φθογγός) added to what was previously the lowest sound of the ancient Greek system of conjunct and disjunct tetrachords. For example, to the sounds BCDE, EFG*a*, forming two conjunct tetrachords in the lowest part of the scale, was added A, an octave below the last of the sounds above named. This formed a series of sounds similar to that of our minor scale when its 6th and 7th are made minor; thus, ABCDEFG*a*, ascending diatonically from A in the lowest space of the stave with bass-clef, to A upon the highest line of the stave with same clef. In this place we may mention that the ancient perfect system, or Immutable System of the Greeks, as it is described by Greek writers on music, appears to have consisted of fifteen sounds comprehended within two octaves, reckoning from the Proslambanomenos above described up to a sound two octaves higher. The order of these sounds, and their ancient Greek names and modern literal names, ascending, are as follows: Proslambanomenos A, Hypate-hypaton B, Parypate-hypaton C, Lichanos-hypaton D, Hypate-meson E, Parypate-meson F, Lichanos-meson G, Mese *a*, Paramese *b*, Tritediezeugmenon *c*, Paranete-diezeugmenon *d*, Nete-diezeugmenon *e*, Trite-hyperbolæon *f*, Paranete-hyperbolæon *g*, Nete-hyperbolæ *ā*. Some of these strings or sounds were called Apycni, Baropycni, Mesopyeni, Oxypycni. Some, too, were *fixed*, and others *moveable.* (For various observations upon Greek scales, and upon certain oriental scales and ecclesiastical scales, see the article MUSIC, and appendix to Graham's *Essay on the Theory and Practice of Musical Composition*, 1838.)

The texts of the ancient Greek writers upon music are so corrupted and so obscure in many respects, and contain so little of a really *practical* or useful nature, that we have purposely refrained from inserting in this work many old

Greek theoretical terms, of which the exact signification is now lost. Attempts to explain these could end in nothing better than vague and useless conjectures. Those who feel any particular interest in the very obscure subject of ancient Greek music, may consult the Greek writers edited by Meibomius and Wallis, and various other ancient writers who treat of music expressly or incidentally; also Hawkins, Burney, Forkel, and others. (G. F. G.)

PROSODY, that part of grammar which treats of the quantities and accents of syllables, and the manner of making verses. This subject, in its various sub-divisions will be found treated of throughout the work.

PROSOPOPŒIA. See PERSONIFICATION.

PROSSNITZ, a town of the Austrian empire, in Moravia, on the Rumza, in the fertile district of Hanna, 11 miles S.S.W. of Olmütz. It contains several churches, a convent, hospital, and military school. Manufactures of woollen and linen cloth, kerseymere, cotton fabrics, and brandy are carried on here; and asparagus is raised in large quantities in the neighbourhood. The largest corn-market in Moravia is held at Prossnitz. Pop. (1851) 11,396.

PROSTYLE. See *Glossary* to ARCHITECTURE.

PROTAGORAS, a celebrated sophist of Abdera, was the son of Artemon or Mæandrios, and flourished 444 B.C. His poverty had compelled him to adopt the humble trade of a wood-carrier, when his countryman Democritus, attracted by the singularly ingenious manner in which he fastened his bundle, admitted him as one of his pupils. After he had profited sufficiently by the instruction of Democritus, he proceeded to Athens, where he opened a school, which was attended by all the most illustrious men of the age. Amongst others, Pericles is said to have been his pupil. Protagoras is said to have been the first who set a price on his instruction, and by this means he was enabled to amass a large fortune. Plato, who was his avowed opponent, is willing to allow that Protagoras possessed a lively and fertile imagination, a wonderful memory, and great eloquence; but he was vain, impudent, and presumptuous; he spoke of his rivals with contempt, and of himself with a degree of confidence which excited the admiration of the vulgar. In the *Theætetus* of Plato we have a summary of the doctrines of this philosopher. He summed up the doctrine of Heracleitus concerning eternal becoming in the well-known proposition: "Man is the measure of the universe, both of that which exists and of that which does not exist." Confutation was accordingly impossible. Protagoras, having in one of his works declared that he could not argue on the nature of the gods because he was not certain of their existence, he was accused of impiety, and condemned to suffer death, or, according to others, banishment. On his passage to Sicily he suffered shipwreck, and was drowned, Frei conjectures, about B.C. 411, and accordingly assigns 480 B.C. as the date of his birth. (See J. Frei's *Quæstiones Protagoreæ*, Bonnæ, 1845.)

PROTECTIONISTS, a name given to that section of the Conservative party which opposed the repeal of the corn-laws, and which separated from Sir Robert Peel in 1846. A "Society for the *Protection* of Agriculture," and to counteract the efforts of the Anti-Corn Law League, gave the name to the party. Lord George Bentinck was their leader from 1846 till his death in September 21, 1848. The administration under Lord Derby not proposing the restoration of the corn-laws, this society was dissolved February 7, 1853. (Haydn's *Dictionary of Dates.*)

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther. In 1529 the Reformed party *protested* against a decree of the Emperor Charles V. and the Diet of Spires, and declared that they appealed to a general council. The same name has now become a common denomination for all those of the Reformed churches.

PROTOGENES, a very celebrated Greek painter, was a native of Caunus in Caria, and flourished 330 B.C., in the time of Alexander the Great, being the contemporary of Apelles. Protogenes lived principally in Rhodes, where he was held in little honour by his neighbours, until Apelles paid him a visit, and declared that Protogenes was only inferior to himself in one particular, that he bestowed too much pains in finishing his paintings. From that moment the reputation of Protogenes was established. (See APELLES.) His finest painting was that representing Ialysus, the grandson of Sol, which he took seven years to finish, having put on it four courses of colour. Having been placed in a temple at Rhodes, when the city was besieged by Demetrius, the painting was in danger of being destroyed, when the conqueror is said to have retired rather than that it should run any risk. It was afterwards carried to Rome and placed in the Temple of Peace, where it was destroyed by fire. There was a dog in this picture, which the painter wished to represent with foam at its mouth; but, after many vain attempts, it is reported he threw his sponge in a fury at the spot, and by a strange accident produced the very effect he wanted. He also painted a satyr playing on the shepherd's pipe, which is said to have been very fine; likewise a portrait of Pythias, the mother of the philosopher Aristotle, a Pan, and portraits of Alexander. According to Suidas, he was the author of two books on painting, now lost.

PROTRACTOR, an instrument for laying down and measuring, with accuracy and despatch, angles upon paper, and by which the use of the line of chords is superseded. This instrument is variously formed, such as the graduated semicircle, the rectangular ruler with graduated edges, and other more expensive contrivances.

PROUT, SAMUEL, a great painter in water-colours, was born at Plymouth in September 1783. His education in art was obtained by a patient and enthusiastic study of nature. He spent whole summer days in drawing the quiet cottages, rustic bridges, and romantic water-mills of the beautiful valleys of Devon. He even made a journey through Cornwall, to try his hand in furnishing sketches for Britton's *Beauties of England.* On his removal to London in 1805, a new scene of activity opened up before Prout. It now became his endeavour to correct and improve his style by the study of the works of the great masters. A great part of his time was also devoted to maintaining himself by means of his art. He painted marine pieces for Palser the printseller. He received pupils, and published many drawing-books for learners. He was likewise one of the first who turned to account in his profession the newly-invented art of lithography. In spite of all this industry, however, it was not until about 1818 that Prout discovered his proper sphere. Happening at that time to make his first visit to the Continent, and to study the quaint streets and market-places of continental cities, he suddenly found himself in a new and enchanting province of art. All his faculties feeling themselves in their congenial element, sprung into unwonted power and activity. His eye readily caught the picturesque features of the architecture, and his hand put them down upon canvas with unsurpassed felicity. The composition of the pictures was exquisitely natural; the colour exhibited "the truest and happiest association in sun and shade;" the delicately-carved remnants of ancient architecture were copied with fond minuteness; and the solemnity of great cathedrals was brought out with striking effect. Encouraged by this success, Prout continued most enthusiastically to pursue that path upon which he had unexpectedly come. At the time of his death, in February 1852, there was scarcely a nook in France, Germany, Italy, and the Netherlands where his quiet, benevolent, observant face had not been seen searching for antique gables and sculptured pieces of stone. In Venice especially there was scarcely a pillar which his eye had not lovingly studied and his pencil had not dexterously copied. (See a Memoir of Prout, by John Ruskin, in the *Art-Journal* for 1849.)

Prout, *William*, a distinguished physician, was born in 1786, and took the degree of M.D. at Edinburgh. Settling in London, he began to apply chemistry to his professional studies. The results of his investigations were published in Thomson's *Annals of Philosophy*, the *Philosophical Transactions*, the *Philosophical Magazine*, and other scientific journals. They also appeared in separate treatises. *An Enquiry into the Nature and Treatment of Gravel, Calculus, and other Diseases connected with a deranged operation of the Urinary Organs*, was produced in 1821. Not long afterwards he published all his discoveries in a collected form, in a treatise *On the Nature and Treatment of Stomach and Renal Diseases.* By these and other labours Prout attained to a position of eminence. He was employed to write a Bridgewater essay on *Chemistry, Meteorology, and the Function of Digestion, considered with reference to Natural Theology.* So successful was his work on *Stomach and Renal Diseases* that it reached a fifth edition in 1848. At the time of his death in 1850, he was a fellow of the Royal College of Physicians of London and also of the Royal Society.

PROVENCE, an ancient province of France, in the extreme S.E. of the kingdom, bounded on the N. by the province of Dauphiné, W. by that of Languedoc, S. and S.E. by the Mediterranean, and E. by Italy. It comprehends the modern departments of Basses-Alpes, Bouches-du-Rhône, and Var; with parts of those of Vaucluse, Drôme, and Hautes-Alpes.

PROVERB (Lat. *proverbium*, i.e., *pro-verbum*), a by-word or saw, has been defined by Erasmus as "Parœmia est celebre dictum scitâ quâpiam novitate insigne" (*i.e.*, a proverb is a well-known saying remarkable for some elegant novelty). Of the numberless attempts at defining a proverb, perhaps the most elegant is that of Cervantes, who describes them as "short sentences drawn from long experience" (*Don Quixote*, part i., c. 39). With the *Opera Moralia* (vol. v., ed. Wyttenbach) of Plutarch, a collection of 131 proverbs are given, with explanations, which may be relied upon as tolerably genuine. To collect and explain such stray portions of the wisdom of the people has engaged the attention of many of the most learned men the world has known. We have the testimony of Laertius, that Aristotle, Theophrastus, and Chrysippus, all engaged in collecting proverbs. Synesius, a writer of the fifth century, quotes from a work of Aristotle, now lost, a description of a proverb: "A proverb is a remnant of the ancient philosophy preserved amid very many destructions, on account of its brevity and fitness for use." Zenobius, who lived in the beginning of the second century, epitomized 552 proverbs of two old writers, Terræus and Didymus; and Diogenianus, his contemporary, made a collection of 775 proverbs. These two collections, with 1400 adages from Suidas, 353 from the Vatican library, and a selection of rhymed adages, were edited by Andrew Schott, 4to, Antwerp, 1612. Michael Apostolius of Byzantium, who lived about the middle of the fifteenth century, collected 2027 ancient proverbs, which were published by the Elzevirs, 4to, Lugd. Batav. 1653. The same house likewise published at Amsterdam, in 1663, a useful epitome of the 4151 adages of Erasmus.

In point of number, originality, and elegance, the proverbs of Spain stand in advance of those of all other countries. They can be traced back to the very earliest times. Many are found in the *General Chronicle*, one of the oldest of Spanish prose compositions; and among them is the happy one on disappointed expectations, quoted more than once in *Don Quixote*:—"He went for wool, and came back shorn." Several occur in the *Conde Lucano* of Don John Manuel, and many in the poetry of the Archpriest of Hita, both of whom flourished in the time of Alfonso XI. Till 1496, when Mendoza, Marques of Santillana, at the request of Juan II., collected for the instruction of Prince Henry a hundred rhymed *Proverbios*, and above 600, "such as the old women were wont to repeat in their chimney-corners," the old and wise proverbs of the language had obtained no settled place in the didactic literature of the country. From that date, however, they began to be turned to account. About the middle of the same century Pedro Valles published an alphabetical list of 4300 old Spanish adages; and Hernan Nuñez de Guzman, the Greek scholar and nobleman, increased the series in his *Refranes* (1555) to above 6000. Mal Lara, a Sevilian, made a selection from this great store of 1000 proverbs, and adding a commentary to each, published them in 1568, under the not inappropriate title of *Philosophy of the Common People* (*La Philosophia Vulgar*). Palmerino, a Valencian, published in 1569 above 200 proverbs appropriate to the table; and Oudin issued a collection of Spanish proverbs for the use of foreigners, at Paris in 1608. Sorapan in 1616–17 issued two collections of medical proverbs; and finally, in 1695, Cejudo, a schoolmaster of Val de Peñaz, gave the world about 6000, with the corresponding Latin adages, where he could find them, and with explanations more satisfactory than had been furnished hitherto. A curious collection of Valencian proverbs was published in 12mo at Valencia, by Carlos Ros in 1733. Notwithstanding the number thus collected, many thousands still remained unpublished, known only among the traditions of the humbler classes, that had given birth to them all. Juan de Yriarte, the king's librarian at Madrid, collected towards the middle of the eighteenth century no less than 24,000; and yet it is supposed he had not nearly exhausted the stock peculiar to the common people of the provinces. There is also a good modern collection of Spanish proverbs in six duodecimo volumes by Repulles. It is, perhaps, not possible to account for the number of proverbs which are found in Spain above any other country in Christendom; but be this as it may, we know they are frequently the most pleasant and most characteristic ornaments of the national literature.

In our own country, among the numerous collectors of proverbs, may be mentioned John Ray the naturalist, who published in 1670 his book on proverbs, which has been frequently reprinted. There is likewise a valuable collection of English proverbs, with lengthened explanations and an ingenious preface by Oswald Dykes, 8vo, London, 1708. In Ray's collection there are, besides English proverbs, Scottish, Welsh, Irish, Danish, Eastern, and Hebrew proverbs. He divides them into various classes, arranges each alphabetically, and winds up by an extensive index to the whole work. The works which Ray consulted were—1. *The Children's Dictionary*; 2. Camden's *Remains*; 3. Clark's Collection; 4. Gent's Collection; 5. Herbert's *Jaculum Prudentum*; 6. Codrington's Collection; 7. Howell's *Parœmiographia.* A new edition of this work has recently (1855) been published by Henry G. Bohn, in which are introduced large additions of proverbs, sayings, sentences, maxims, and phrases, under the title of *A Handbook of Proverbs.*

PROVERBS, The Book of. That Solomon was the author of the Book of Proverbs has seldom been questioned. Some have indeed thought that he composed a part only of the Proverbs included in that book, and collected the others from various sources. It is probable, indeed, that he availed himself of any sayings already current which he regarded as useful and important. Whether he ever made any *collection* of his proverbs in writing is somewhat doubtful. From the twenty-fifth chapter to the end of the book, we are expressly informed, was written out and added to the previous portion, by order of King Hezekiah. The divine authority of the book is sufficiently proved by the quotations made from it in the New Testament (Rom. xii. 16; Heb. xii. 5, 6; 1 Pet. iv. 8; 1 Thess. v. 15). It has in all ages, indeed, been regarded as a great storehouse of practical wisdom. The early fathers were accustomed to call it *πανάρκετος σοφία*. Modern writers have been equally filled with admiration of the profound knowledge of human nature displayed in it, its accurate delineations of character, and the wonderful richness and appropriateness of its instructions.

The Hebrew word rendered *proverbs* (מָשָׁל, *maushal*), is derived from a root which means,—1. *To resemble, to compare;* 2. *To rule;* and signifies primarily *a similitude* or *comparison* of two objects. Many of the proverbs of Solomon are of this nature,—*e.g.*, x. 26; xxv. 11, 12, 13, 14, 18, 19, 20, 25, 26, 28. Hence the meaning of the word may have been gradually extended so as to embrace any apophthegm or brief pithy saying. Or we may consider this meaning to have been derived from the other signification, viz., *to rule;* whence authoritative maxims. The idea of *resemblance*, however, seems to be the prominent one, and may refer to the figurative style common in proverbs, even when no direct comparison is instituted. And as highly figurative language belongs to poetry, it came to pass that *maushal* was used to indicate any composition expressed in a highly ornamented and poetic style. Thus the prophecy of Baalam is called *maushal* (Num. xxiii. 7). The characteristics of the proverbial style (in the more restricted sense of the word) are, according to Bishop Lowth,—1. Brevity; 2. Obscurity; 3. Elegance. The first of these is, however, the only one that can be considered at all universal. We should be rather inclined to name, as a characteristic of the proverb, a pointed and sometimes antithetical form of expression; and this, in addition to brevity or sententiousness, constitutes perhaps the only universal distinction of this species of composition. Conciseness indeed enters into the very essence of the proverb; and this fact is probably indicated by the word itself; *proverbia, for* or *instead of words,—i.e.*, one word for many. From what has been said of the characteristics of the proverbial or parabolic style, it is obvious that it possesses peculiar advantages as a medium of communicating truth. The proverb once heard remains fixed in the memory. Its brevity, its appositeness, its epigrammatic point, often aided by antithesis or paronomasia, not only ensure its remembrance, but very probably its recurrence to the mind at the very time it is needed. The advantages above specified apply to the proverbial mode of writing in any age and among any people. But Solomon must have had other reasons for selecting it, peculiar to the age and country in which he lived. The Hebrews have been called a nation of children. We find this mode of writing employed in the most remote ages; and wise sayings, maxims, apophthegms, constitute a large part of the early literature of most nations. Especially is this true of the orientals. Recent travellers in the East assure us that the reverence for proverbs still exists there; and that nothing gives a man so much advantage in an argument as the ability to quote one of them on his side. We may therefore conclude that the wise king could have found no better mode of impressing truth on the minds of his countrymen than the one he has here chosen.

As to the style of the book of Proverbs, we find it to be marked by those characteristics which distinguish the poetry of the Hebrews from their prose compositions. Of these, one of the most obvious and important is what has been termed *parallelism*. This consists in a certain resemblance or correspondence, either as to thought or form, or both, between the members of a period. The two most simple kinds of parallelism, and the only two we shall notice here, are when the period contains but two members, and the last either repeats the thought contained in the first, or presents an antithetical assertion, beginning generally with the adversative *but*. The first kind of parallelism is called by Lowth *synonymous*, the second *antithetic*. The following passage is a beautiful example of synonymous parallelism:—

> "My son, if thou wilt receive my words,
> And hide my commandments with thee;
> So that thou incline thine ear unto wisdom,
> And apply thine heart to understanding;
> Yea, if thou criest after knowledge,
> And liftest up thy voice for understanding;
> If thou seekest her as silver,
> And searchest for her as for hid treasures;
> Then shalt thou understand the fear of the Lord,
> And find the knowledge of God." (Prov. ii. 1–5.)

As an instance of antithetic parallelism, take these verses:—

> "The fear of the Lord prolongeth days;
> But the years of the wicked shall be shortened.
> The hope of the righteous shall be gladness;
> But the expectation of the wicked shall perish.
> The way of the Lord is strength to the upright;
> But destruction shall be to the workers of iniquity."
> (Prov. x. 27–29.)

It will be perceived that there is a continuity in the former of these passages which does not belong to the latter. In fact the first nine chapters of the book of Proverbs are remarkably distinguished from the remainder, and constitute a sort of proem or exordium to the work. This portion was probably committed to writing, while the disconnected aphorisms which compose the greater part of the remaining portion were only uttered. It is a continuous discourse, written in the highest style of poetry, adorned with apt and beautiful illustrations, and with various and striking figures. The personification of Wisdom in these chapters is universally regarded as one of the most beautiful examples of prosopopœia to be found in the Bible, and possesses an indescribable grace and majesty. At the tenth chapter a different style commences. From ch. x. to ch. xxii. 17 is a series of pithy disconnected maxims, on various subjects, and applicable to the most diverse situations. From ch. xxii. 17 to ch. xxv. a style resembling that of the exordium, though inferior in elegance and sublimity, prevails; and at the twenty-fifth chapter the separate maxims recommence. These compose the remainder of the book, with the exception of the thirtieth chapter, which is ascribed to Agur, and the thirty-first, which is said to be the advice given to King Lemuel by his mother. Who these persons are is not known. The supposition that Lemuel is another name of Solomon does not appear to be supported by proof. The thirtieth chapter affords an example of another species of writing closely allied to the proverb, and equally in favour among the Orientals. It is that of riddles or enigmas designed to exercise the wit and ingenuity of the hearer, and to impart instruction through the medium of amusement. The concluding chapter, containing the counsels addressed to King Lemuel by his mother, needs no elucidation. It presents a beautiful picture of female excellence in an age and country where modesty, industry, submission, and the domestic and matronly virtues were esteemed the only appropriate ornaments of woman.

The literature of the book of Proverbs is contained chiefly in the following works (besides the preliminary dissertations in the various Commentaries):—Melancthon, *Explicatio Provv.* 1555; Mercer, *Comment in Provv. Salom.*; Geiero, *Provv. Salom.* 1669; Schultens, *Proverbia Salom.* 1748; Hirtz, *Vollst. Erklär. der Sprüche Salom.* 1768; Hunt, *Observations on the Book of Proverbs*, 1775; Hodgson, *On the Book of Proverbs*, 1778; Jager, *Observatt.*

in Prov. Salom. Versionem Alexand. 1788; Lawson, *Exposition of Proverbs*, 1821; Umbreit, *Philol. Krit. u. Philosoph. Comm. ü. d. Sprüche Salom.* 1826; and Moses Stuart, 1850. There are also translations, mostly with notes, by J. D. Michaëlis, 1778; Doederlein, 1786; Streunsee, 1783; Kleuker, 1786; Reichard, 1790; Ziegler, 1791; Muntinghe, 1800, 1802; Dahler, 1810; Holden, 1819; Gramberg, 1828; Böckel, 1829; Ewald in his *Poet. Büch.*

PROVIDENCE, a town of the United States of North America, one of the capitals of the state of Rhode Island, on both sides of the Providence River, where it falls into Narraganset Bay, 35 miles from the sea, 43 S.S.W. of Boston, and 175 N.E. of New York. The extremity of Narraganset Bay is formed by an oval-shaped sheet of water inclosed by stone masonry, and lined by a broad public walk with many shady trees. Close to this stand the railway stations for Boston, Stonington, and Worcester, conveniently situated in close connection with each other, and in the middle of the business portion of the town. The river is crossed by several well-built bridges. The plan of the town is irregular, on account of the unevenness of the site, which rises into several hills; and the houses are generally built of wood, though in some more substantial and splendid materials have been employed. Providence contains many large and imposing public edifices. Among these is the Arcade, a granite building with a glass roof, 226 feet long and 80 broad. It is three storeys in height, contains more than eighty shops, and has two fronts, each adorned with a Doric portico. "What Cheer Building," so called from the salutation addressed by the Indians to the earliest settlers here, has recently been erected for the accommodation of the public offices. Besides the State-House, Market-House, and other buildings, the town contains about thirty-five churches, some of which are of considerable architectural merit. Providence is distinguished for the number of literary and academical institutions it contains. Of these, the principal is Brown university, a seminary under the management of the Baptists, founded in 1764, and removed hither in 1770. The edifice, which occupies the highest site in the town, comprises four large and elegant halls: Rhode Island Hall, containing the lecture-rooms and museum; Manning Hall, the library of 19,800 volumes; University Hall and Hope College, the residences of the students, who were, in 1857, 236 in number. There are in all about fifty schools in the town of various grades, from elementary to high schools; and they are attended by upwards of 6000 pupils. The athenæum, founded in 1836, occupies a handsome stone edifice, containing a reading-room and library of 10,000 volumes. The state normal school, which was established here in 1854, had in 1856 an average attendance of 66 pupils. There is also here a reform school for juvenile delinquents, containing, in 1856, 99 boys and 44 girls. Butler Hospital, for the insane, opened in 1848, has extensive grounds, and can accommodate about 145 patients. It contained in 1855, 137. The Dexter Asylum for the poor, occupying a good brick building, with 40 acres of grounds, is another of the benevolent institutions of Providence. The state prison is situated here; and it contained in 1856, 76 prisoners. The manufactures of Providence and its vicinity are many and large, employing a capital of more than L.1,000,000. Hardware, machinery, carriages, furniture, jewellery, woollen and cotton fabrics, are the principal articles produced. The water-power afforded by the river is employed for moving flour and saw mills, and for sawing and polishing marble. Steam-power is also made use of to a great extent. The harbour is safe, and admits vessels of 900 tons. The trade of the port was formerly very extensive, especially with the East Indies and China; but it is at present in a somewhat declining condition. Molasses, sugar, coal, salt, and iron are imported from foreign countries; cotton, flour, grain, hay, &c., from other places on the coast. The total value of the imports from foreign countries in 1852 was L.36,504, and of the exports of domestic produce to foreign lands L.8656. The amount of duties collected at the port was L.8015. The tonnage of the shipping registered 30th June 1852 was 9095; of those enrolled and licensed, 7327. In the year ending at that date there entered from foreign ports 57 vessels, tonnage 7944; and there cleared 60, tonnage 9876. Providence contained, in 1853, 31 banks, and the total bank circulation 19th April 1858 was L.309,005. The town was founded in 1635, and incorporated as a town in 1649. It is now next to Boston among the cities of New England for wealth and population. Pop. (1850) 41,512; (1853) about 47,500.

PROVINCE WELLESLEY, one of the Eastern Straits settlements, belonging to Great Britain, in the Malay Peninsula, bounded on the N. and E. by the native state of Quedah, S. by that of Perak, and W. by the sea; length, 53 miles; breadth, 4; area, 140 square miles. The surface, which is slightly undulating, slopes gradually towards the sea. The soil is in general swampy, but not unproductive, being very suitable for the cultivation of rice. In some places there are narrow strips of sandy ground, where cocoa-nut trees grow well. The geological formation of the district, like that of the island of Penang, is granitic. The climate is hot, but salubrious, the mean temperature being about 80°. When first occupied by the British, this country was covered with a thick impenetrable jungle, haunted by tigers, leopards, rhinoceroses, elephants, and other wild beasts. It has, however, been since that time much improved, and about 120 square miles of the country are under cultivation. Rice is the principal crop, but sugar is also raised in the central and southern portions. The most important of the other productions are indigo (not of the best quality) and cocoa-nuts. Poultry and cattle are sent from this settlement to that of Prince of Wales Island. Province Wellesley was obtained from the King of Quedah for a sum of money in 1802. It is subject to the governor of Prince of Wales Island. Pop. (1855) 51,509.

PROVINCIA (an abbreviated form of *providentia*) seems, as to its original meaning, to indicate a duty, or a matter entrusted to one; but is generally applied to a territory beyond Italy, which had a regular organization and was under Roman administration. The Roman state in its ultimate development consisted of two parts, with a separate organization,—Italia and the Provinciæ. There were of course no provinces in this sense of the word until Rome had extended her conquest beyond the confines of Italy. Sicily was the first Roman province, B.C. 241, and Sardinia was the second, B.C. 235; and Gallia Ulterior, in Cæsar's time, is called in the *Commentaries* simply by the name *Provincia;* whence the modern term Provence.

When a country was conquered it received its provincial organization either from the Roman commander, or from a body of senators assisted by that commander. Prætors were at first appointed to the oversight of provinces; but subsequently they received those governments upon the expiration of their official year at Rome, and were called proprætors. In later times of the republic the consuls were appointed to provinces in a similar way, with the title of *proconsules.* Such provinces received the designation of *Consulares.* Their term of office as governor of the provincia was usually a year, but it was frequently prolonged. There was no pay attached to the office, but certain expenses were provided for out of the Ærarium. A considerable change was made by Augustus on the administration of the provinces. Where a large military force was necessary, he took charge of the province himself, and left the others to the care of the Roman Senate and people. The provinciæ were accordingly divided into *propriæ*

Populi Romani and *propriæ Cæsaris*,—a distinction which was observed till the third century.

The Roman provinces, as enumerated by Sigonius down to the battle of Actium, are as follows:—Sicilia, Sardinia et Corsica, Hispania Citerior et Ulterior, Gallia Citerior, Gallia Narbonensis et Comata, Illyricum, Macedonia, Achaia, Asia, Cilicia, Syria, Bithynia et Pontus, Cyprus, Africa, Cyrenaica et Creta, Numidia, Mauritania. Those of a newer date were, according to the same writer, Rhætia, Noricum, Pannonia, Mœsia, Dacia, Britannia, Mauritania Cæsariensis and Tingitana, Ægyptus, Cappadocia, Galatia, Rhodus, Lycia, Commagene, Judæa, Arabia, Mesopotamia, Armenia, Assyria. Under Augustus, Gallia was divided into the four provinces of Narbonensis, Celtica or Lugdunensis, Belgica, and Aquitania. It should be observed that one marked distinction between the administration of Italy and that of the provinces was, that in Italy the towns had *magistratus* and *jurisdictio*, while in the provinces, except where the Jus Italicum had been granted, the governor alone had *jurisdictio*. Under the imperial rule, however, a greater uniformity was introduced; and ultimately the whole of Italy was under a provincial form of government. (See Sigonius, *De Antiquo Jure Provinciarum*, lib. i.–iii.; the works of Gœttling and of Walter; and a judicious article by George Long in Smith's *Dictionary of Greek and Roman Antiquities*, 1851.)

PROVINS, a town of France, capital of an arrondissement in the department of Seine-et-Marne, on the small rivers Vouzie and Durtein, which unite here to flow into the Seine, 29 miles E. of Melun. This ancient but now decayed place lies between two hills, and consists of an old and a new town,—the former on the upper ground, the latter on the slopes beneath. Its ancient walls, which, with their flanking watch-towers, still exist, inclose, besides the buildings, a wide space of ground laid out in gardens and vineyards. The streets of the old town are for the most part narrow and irregular, its houses ill built and dilapidated; while the new town, on the other hand, contains regular streets and good houses. The most conspicuous object in the former is a large and solid mediæval tower, called the *Grosse Tour de César*, serving as the belfry of the old and massive church of St Quiriace. The new town contains several interesting and curious churches, two hospitals, a market-house, college, school, and cavalry barracks. The rivers are employed to drive many flour-mills, and there are numerous dye-works along their banks. Earthenware, linsey-woolsey, and conserve of roses are also made here. The roses of Provins have for ages been celebrated for their rich crimson colour. They are said to have been brought from Palestine by the Crusaders in the thirteenth century, and are incorrectly called Provence roses. Some trade is carried on in these flowers, as well as in corn, flour &c. Pop. (1856) 6198.

PROVOST (Sax. *profost*, from the Latin *præpositus*, placed before), is a name applied to the chief municipal magistrate in corporate towns or cities in Scotland, and corresponds to the English term mayor. He presides in civic courts, and with the bailies, who are his deputies, determines in all differences that arise amongst citizens. The word is seldom used in England, except when it is applied to the heads of certain colleges, such as Eton, King's College, Cambridge, &c.

PRUDENTIUS, Aurelius Clemens, a Christian poet of some celebrity, who flourished under the reign of Theodosius the Great, was born in Spain in the year 348 A.D. He first followed the profession of advocate, was afterwards a judge, then a soldier, and at length had an honourable employment at court. Nothing more is known about him. A great number of his poems remain; but the style is barbarous, forming a singular contrast to the purity of the Augustan age. The most complete and splendid edition of his works is that of Faustinus Arevalus, 2 vols. 4to, Rom. 1788–9. That of Obbarius (8vo, Tübingen, 1845) will also be found satisfactory. (See H. Middledorpf's *Comment. de Prudentio Theodosia Prudentiana*, 1823–7.)

PRUSSIA.

History.

The Prussian monarchy, at present the smallest among the great powers of Europe, has been formed by the addition of divers portions and provinces of Germany to the country originally called Prussia. The latter country, although it gave its name to the monarchy, and although upon it the royal dignity was conferred, has, however, not served as the nucleus around which the state crystallized into form, this honour being allotted to the marquisate (in later times the electorate) of Brandenburg. With the history of Brandenburg, therefore, particularly since the accession to its rule of the Hohenzollern dynasty, our task will mainly lie, as we attempt to draw a short outline of the rise and progress of the Prussian monarchy.

Ancient history of Brandenburg.

At the beginning of the Christian era we find the territory afterwards called Brandenburg inhabited by German tribes, which, in the succeeding centuries, were carried along by that tide of migration westward and southward that led to Teutonic settlements in all parts of the Roman empire. Their place was soon filled by Slavonic races, gradually advancing as far as the River Elbe, where they remained unmolested until the kingdom of Germany was established by the successors of Charlemagne in the treaty of Verdun, A.D. 843. A kind of military colonies, called *Marches*, were now everywhere founded for the defence of the frontiers. Thus, in 930 we find the North March established by command of the emperor, at present the north-west corner of Brandenburg; and soon after, the East March, which corresponds to the present Nether Lusatia. Meanwhile Otto I., Emperor of Germany, had founded the bishoprics of Brandenburg and Havelberg; and desultory warfare, aided by the labours of an active priesthood, began to extend the boundary of German jurisdiction in those parts. This forward movement found a powerful representative in Markgraf Albrecht the Bear, formerly Duke of Saxony. By his valiant exploits in 1157 against Zazko, a chieftain of the Slavonic tribe called Wends, and by the firm civil and military organization he gave to the greatly-augmented territories under his rule, he became the real founder of the marquisate of Brandenburg. His family, the Ascanians, followed in his footsteps, gradually, in the course of a century and a half, Germanizing the conquered districts by the introduction of German immigrants; establishing new towns, or endowing old ones with considerable privileges; extending their territory by conquests and intermarriages to parts of Pomerania in the north, and to parts of Saxony, Lusatia, and Silesia in the south-east. On the decease of the last of this dynasty, A.D. 1320, anarchy threatened to wipe away for ever the happy germs of civilization in these parts. Feuds among the lords and barons, and devastating inroads of neighbouring princes covered the land for nearly a century with bloodshed and rapine. The Emperor Louis of Bavaria had, on the demise of the last Ascanian, bestowed the Marquisate on his son Louis, not then of age. This Markgraf Louis added the new dignity of Elector of the Holy Roman Empire (Furfürst) to that of *Archicamerarius Truperii* (Erzkämmerer), which his Ascanian predecessors had already held. But this great accession of rank to the German princes did not invest him or his immediate successors with that firm grasp over the unruly nobles, and that protective power against encroaching neighbours which were necessary in so exposed a situation as that of the electorate of Brandenburg. The third of these Bavarian rulers was forced by financial difficulties to cede his territories to the Emperor Charles IV., whose main object seems to have been to turn the Kur-march into a hereditary property of his own family of Luxemburg. First, his eldest son Wenceslas of Bohemia, and afterwards a younger son, Sigismund, then only eleven years old, were created electors of Brandenburg, much to the detriment of this miserable country. Sigismund, as precocious in borrowing money as he was in obtaining dignities, twice gave over his fief of Brandenburg as a mortgage for his debts. The first of these cessions was to his cousin Todorus of Moravia. This prince was more successful in the extortion of money from his impoverished subjects in Brandenburg than in the chastisement of a nobility now entirely masters of a country which they robbed and devastated at random. Fortunately for it, Sigismund was still deeper in debt, when, on the decease of Todorus in 1411, he found himself emperor of Germany, and Brandenburg again at his disposal. Frederick of Hohenzollern, Burggraf or imperial commissioner at Nurnberg, had lent the Emperor Sigismund 400,000 gold florins, and was ready to waive this demand in return for a gift which at that time would have possessed but little attractions to many,—viz., the electorate of Brandenburg. In the year 1415, Frederick having held the lands in pawn during four years, was raised to the dignity of elector, and received the solemn investiture at the Diet of Constance in 1417 with great pomp and ceremony. Providence had graciously ordained that with him this should be no idle and unmeaning pageant, but the commencement of an era of good government, of steadfast progress, and of sober attention to the labours of the state, which, handed down in his highly-gifted family, has gradually and almost insensibly raised that small and poor electorate of Brandenburg into a kingdom of the first order among European powers, and of great promise for the progress of the civilization of the world.

The Hohenzollern family.

A few words will suffice to introduce the reader to the previous history of the Hohenzollerns. Their name is derived from the castle of Zollern or Hohen-zollern in Swabia, and their lineage is traced upwards to a Count Thassilo, who lived in the days of Charlemagne. In the year 1200 the *cadet de famille*, one Conrad, received the appointment of burg-graf of Nurnberg. From him the electoral and royal dynasty of Hohenzollern have descended in an unbroken line, whilst the older branch of the family, being descendants of Conrad's eldest brother Frederick, remained princes of a small territory contiguous to their ancestral castle of Hohenzollern; until in 1851 they gave over their sovereignty to the King of Prussia, and they now reside in the Prussian dominion as princes of the blood. The present (1859) prime minister of Prussia, who is also father of the Queen of Portugal, is one of these princes of Hohenzollern. The Burggrafs of Nurnberg had, before obtaining Brandenburg, become lords of Ansbach and Baireuth, two small territories in Franconia. It may be as well to state here that these territories of Ansbach and Baireuth, after having remained a much-prized property under several hands in the electoral line of Hohenzollern during many centuries, came in 1806 into the possession of Napoleon, who in 1810 incorporated them with Bavaria.

Frederick ., Elector of Brandenburg

From the very beginning of his rule in 1412, Frederick had been assiduously intent upon saving the country from the effects of anarchy. "The towns, harried and plundered to skin and bone, were glad to see him, and did homage to him with all their heart. But the baronage or squirearchy of the country were of another mind. These in the late anarchies had set up for a kind of kings in their own right; they had their feuds, made war, made peace, levied tolls and transit dues; lived much at their discretion in these solitary countries." On their refusing homage, "Frederick was very patient with them, hoped to prevail by gentle methods, but could make no progress in that way." Force was applied; in spite of drawbridges and thick walls, the feudal castles fell before what little artillery Frederick could muster against them, and with their destruction, order and obedience to the laws entered the long-distracted country. He understood the noble art of governing men; had in him the justice, clearness, valour, and patience needed for that. Except in the Hussite wars for Sigismund and the German empire, in which no man could prosper, he may be defined as constantly prosperous. To Brandenburg he was, very literally, the blessing of blessings; redemption out of death into life." Making every allowance for the shortcomings of several individuals in the long list of Hohenzollerns who followed Frederick on the throne of Brandenburg, there has been something in all that reminds the attentive student of the character of this founder of their dynasty: regular and unflinching progress in all essentials of policy without undue attention to externals—moderation in expense and luxury—manly perseverance in their rights—advancement of the country in the arts of peace as well as of war—protection of their people against the insolent bearing and oppression of the nobles.

Elector Frederick II.

Elector Albrecht.

Elector Joachim I.

Elector Joachim II.

Frederick I. bequeathed Brandenburg, with the electorship, to his second son Frederick II., who obtained the title of "Irontooth" by his military prowess. New acquisitions of territory, by conquest, purchase, or intermarriage, mark his rule (1440 to 1470), as well as that of his two successors Albrecht Achilles and John I.; the former of whom becomes important by his famous family-ordinance (*Hausgesetz*, A.D. 1477), in which it was enacted, that for the future the marches should remain undivided in the hands of the elector; also that the Franconian principalities (viz., Ansbach and Baireuth) should never go to more than two heirs. Thus a real state was formed, and a centre of gravitation provided, to which in the then chaotic state of the empire many a floating mass must needs agglutinate itself in the course of time. Albrecht Achilles' family-ordinance was afterwards confirmed and sanctioned afresh by the Elector Joachim Frederick's house-treaty of Gera. Order and progress in cultivation were on the increase throughout the country, colonists flowing into it from other parts of Germany; so that the beginning of the sixteenth century saw the last of the feudal castles fall under the powerful arm of the Elector Joachim I. (1499 to 1535). The first university in the electorate of Brandenburg was founded A.D. 1506 at Frankfort on the Oder, and a supreme and independent tribunal (*Kammergericht*) organized at Berlin. It is strange, indeed, that this wise and intelligent prince should have carefully avoided every contact with the Reformation, which was spreading far and wide among his people, giving a new and higher tone to their tenor of life, and which was destined to become the corner-stone of his state. The noble task of introducing a more evangelical form of Christianity into the Brandenburg possessions was reserved to his son, the valiant fighter Joachim II. (1535 to 1571), called, "Hector" from the Turkish campaigns in which he had been imperial-generalissimo. It was in the year 1539 that Joachim II. solemnly partook of the Holy Communion according to the Lutheran rite. The three bishoprics of Brandenburg, Havelberg, and Lebus were incorporated into the electorate, and their immense revenues applied to the endowment of schools and charitable institutions. One of his political transactions, though little spoken of at the time, was destined to become the germ of one of the greatest wars the world ever saw, viz., a hereditary union (*Erbverbrüderung*) with Duke Frederick of Liegnitz, signed in 1537, by which, in a certain event, the Silesian principalities of Liegnitz, Brieg, and Wohlau, were to become the inheritance of the Hohenzollern family. Our readers will see that we are pointing to the origin of those Silesian difficulties two centuries later, and their effect on the Seven Years' War; which, in the same degree as they redounded to the military glory of their hero, have been up to the present day represented as having sprung from an arbitrary violation of every law, human and divine. Another important step was made by this elector, when he obtained, in 1569, the co-infeftment of the country called Prussia, which had lately changed its semi-monastic character into that of a secular duchy under the feudal seigneurship of Poland, and under the immediate rule of its first duke, who was a prince of the Hohenzollern family. We shall see that, before long, the sudden decay of the ducal family of Prussia led to the complete union of the two countries under the rule of a Brandenburg elector. John George, elector from 1571 to 1598, deserves our notice, because he opened a ready hand of welcome to a numerous class of Dutchmen driven out of Holland by religious intolerance, and assisted them in settling within his dominions; an example which several of his successors have on occasion followed, much to the advantage of the country,—giving protection to refugees, respectable, hardworking, and accomplished in various branches of industry. His was a reign of thrift and order, by which he succeeded, with the help of considerable grants from his *Stände* (*états*, or provincial parliaments), in removing the consequences of his father's financial maladministrations. Considerable acquisitions accrued to his grandson John Sigismund (1608 to 1619), who not only laid the foundation, on the far west, of the now important state possessions on the banks of the Rhine, by obtaining certain portions of the so-called Cleve inheritance; but also (in 1618) united the dukedom of Prussia to his family.

Elector John George.

Elector John Sigismund.

Previous history of Prussia.

Of this Baltic country, whose destinies henceforward remained interwoven with those of Brandenburg, it behoves us now to say a few words, in order to explain how a German commonwealth had sprung up in these distant regions of the N.E. among a Lithuanian population.

The aboriginal Prussians, of a race belonging to the Lithuanian family, were the inhabitants, from time immemorial, of the territory along the coast between the Vistula and the Niemen. Many had been the attempts to introduce Christianity among this heathenish people on the part of the Polish clergy and the Polish kings; but the Prussians believing, for reasons of their own, that these missionary enterprises were but a cover to political annexation, rallied to withstand them, and finally, much irritated by military demonstrations, entered Poland in great numbers. Their inroads became so alarming that the kings of Poland resolved upon calling to their aid the Teutonic order of the Knights of St George, who would, it was thought, in the absence of Moors and Saracens, be found ready to open a crusade upon that heathenish population. The request was promptly acceded to by Hermann von Salza, the then Deutschmeister, or general of the order, who, however, before setting out, obtained from the emperor a declaration by which all the Baltic lands hereafter to be conquered by his Teutonic knights should become a possession of the order. A long, steady, and well-planned war of conquest ensued (1230 to 1283), in which, with a far smaller amount of needless cruelty than was usual in those days of extermination, the whole country of the Prussians was subjected to the order's rule. Castles and towns were built wherever security demanded or commercial advantages seemed to invite. So great a value was attached by the Teutonic knights to this profession, that in 1309 they removed the head-quarters of their order from Venice to their new palace of Marienburg, which is to this day a witness to their refined taste and their regal magnificence. In all matters the order seemed to be prosperous, and to deserve its progress. Not only did its influence and its conquests soon extend beyond the limits of Prussia, but agriculture, commerce, and the fine arts flourished within their dominions; schools were founded, and law equitably administered. At the time of their greatest prosperity, about the year 1400, the Teutonic knights owned 55 walled cities (several of them important centres of commerce), 48 castles, 19,000 villages, and a nett revenue of 800,000 Rhenish guilders (L.65,000), a vast sum in those days. Luxury, however, and insolent bearing had speedily followed wealth and security, and a single defeat in the great battle of Tannenberg, A.D. 1410, lost against the united forces of the King of Poland and the Lithuanian people, sufficed, if not to drive them out of their possessions, yet to break their independent power. As soon as the great individual valour and skill of their master had procured them an honourable peace they fell out among themselves, one party calling in the Poles to their assistance, and reduced their means to such an extent by internecine warfare that, in the year 1466, the western portion of Prussia was entirely delivered over to the King of Poland, and the order must needs be satisfied to retain its hold on the eastern portion as vassals to the king. In this extremity, the knightly commonwealth of the Teutonic order, in order to obtain protection from without, began the system of electing to the office of masters younger sons or cousins of powerful German dynasties. One of these masters, elected A.D. 1511, was Markgraf Albrecht of Brandenburg-Kulmbach, whose additional recommendation lay in his being the nephew of the King of Poland. Albrecht, however, met with no lenient treatment at the hands of his uncle, but was on the first opportunity attacked by an overwhelming army of the Poles. A truce was no sooner concluded in 1521 than Albrecht hastened to Germany to invoke his countrymen's assistance. He was everywhere disappointed. But the power of the Reformation was so forcibly impressed upon his mind that on his return he declared his adherence to its tenets, with the consent of several of his bishops, and under the acclamations of the nobles and the people. After his liege lord's sanction had been obtained in the peace of Krakau, Albrecht, as a consequence upon the dissolution of his religious order, was proclaimed hereditary duke in the secularized country of Prussia in the year 1525. Convinced of the necessity of establishing the Reformation on the firm basis of sound religious and national education, he opened many schools throughout the country, and founded the university of Königsberg, which continues to this day to stand in the vanguard of mental culture towards the East. But Albrecht's dynasty was not destined to last. His son and successor became hopelessly lunatic. A regency had to be appointed, which, after having been in the hands of other relatives, was conducted from the year 1608 by one elector, John Sigismund of Brandenburg, until in 1618, the dukedom falling vacant by the melancholic duke's death, he took possession of Eastern Prussia, the western part still remaining a province of Poland.

We have thus returned to the fortunate Elector John Sigismund, whose matrimonial alliance with his cousin of Prussia, and the co-infeftment bestowed upon his father, combined in procuring his family a permanent possession (although, for a long time to come, under the feudal *suzeraineté* of Poland) in this farthest north-east corner of civilized Europe. But at this point the hereditary good fortune seemed to desert the family of Hohenzollern. Instead of uniting the north and south-west of Germany, Elector George William.

Frederick William the Great Elector.

which was almost entirely Protestant, into a league under its leadership, and thus probably saving the Germans from a terrible war, Brandenburg receded from the foremost rank in the defence of religious liberty, and suffered deservedly from the wrath and contempt of both contending powers. That fearful struggle, "from the effects of which Germany seems only now to be recovering herself,"—the Thirty Years' War (1618–1648) broke out during the latter years of Elector John Sigismund. His successor, George William (1624–1640), the first utterly incompetent ruler in his family, allowed a violent Papist (believed to have been in the pay of Austria), Count Schwarzenberg, to direct his councils. Neutrality seemed the only desire of this despicable prince's heart. Remaining everybody's friend in a time of unequalled fury, he saw his country trampled under foot by all princes and all armies. Forced by Gustavus Adolphus to declare himself in his favour, he very shortly broke his partizanship. Brandenburg, already impoverished and exhausted by the imperial and Bavarian troops, was now regularly fed upon by a numerous Swedish armament for a number of years. Famine and pestilence cut off the population by thousands; so that, at the time of George William's death in 1640, a traveller would see not only a large number of towns and villages utterly ruined, their trade and commerce annihilated, and even agriculture at a stand-still, but, in the literal meaning of the term, uninhabited tracts, miles after miles, of land, without a living soul upon them. To Frederick William, who succeeded in this year to the dominion of Brandenburg at the early age of twenty, the gratitude of his people and the consent of his contemporaries have ascribed the surname of the "Great Elector." Endowed with a powerful and comprehensive mind, and confident in the moral resources of his people, who soon took courage under his rule, he speedily assumed so imposing a position that the Swedes evacuated the country of their Protestant ally, whilst he cleared by armed force his Rhenish possessions. The elector's voice made itself heard again in the cause of religious toleration during the conferences which were opened at Munster and at Osnabruck in the following years. When the peace was at last concluded, Frederick William could congratulate himself on having regained possession of almost all the territories which had escaped the weak grasp of his father. Almost the only exception to his success was the refusal of the emperor to entertain his claims on the above-mentioned Silesian principalities, which had fallen vacant in 1675, during the reign of George William, and were withheld by that potentate.

To heal the wounds of so protracted and inglorious a devastation, and to secure his straggling possessions from encroachment, was no easy task. It did not escape the elector's observation that the German empire, to whose interests his family had loyally been devoted, could not, in its rotten constitution, long retain much vitality, or any protective power whatsoever. He therefore resolved to give to his state as independent a position in Germany as he could. For this state he saw dangers menacing on all sides,—from the West, in the grasping tendencies of France, then fast approaching the Rhine; from the north, in the yet unbroken war-spirit of the Swedes; and from the East, in the feudal *suzeraineté* which Poland held over his duchy of Prussia. Proceeding step by step, he formed a very efficient though small army, which soon made the name of Brandenburghers to sound as well in the ears of military men as any name in Europe. These troops, assisted by an ever adroit and temporizing policy, procured him, during the sanguinary war which Charles Gustavus waged against Poland, the full and unrestricted sovereignty over his portion of Prussia. In A.D. 1660, before the German empire or any of his German compeers had come to his assistance, he sallied forth to recover the Rhenish possessions of his family (Cleves, &c.), which an invading army of Louis XIV. had wantonly occupied, without even a declaration of hostilities, during a war between France and Holland. So skilful was his strategy that the French, in order to deliver themselves from this most strenuous antagonist, offered subsidies to the King of Sweden for an immediate attack upon Brandenburg, left apparently defenceless by the elector's Rhenish campaign. From Pomerania, of which a portion had been consigned to them in the peace of 1648, they broke in upon Brandenburg, and committed such ravages that their name is proverbially held up in terror to the present day. Whilst they thought him still drilling his troops in the south of Germany, he suddenly attacked them, first at Rathenow, and then, following up his success, a few days later gained a decisive victory near Fehrbellin, on the 28th of June 1675, over a force twice his own number, under the best warriors of that day. The elector left them no time to renew their forces by fresh recruits; and in a brilliant campaign conquered Swedish Pomerania, including the island of Rügen. He reduced even the fortress of Stralsund, which the famous Wallenstein had not many years before vainly attacked with his mighty host. It availed the Swedish commanders but little to create a diversion by a descent upon the duchy of Prussia. Frederick William was soon on their track, and his troops, crossing an arm of the sea on sledges in the depth of winter, drove the enemy from a position in which they had deemed themselves unassailable. Meanwhile, however, the emperor had concluded peace with their common enemies; and thus Frederick William, left entirely alone, was obliged to sign the treaty of St Germain-en-Laye, by which almost every legitimate fruit of his labours was lost. Before he placed his signature to this deed, he gave vent to his bitter feelings against the emperor by exclaiming,—"Exoriare aliquis nostris ex ossibus ultor," and desired his chaplain to preach his thanksgiving-day sermon on the 9th verse of Psalm cxvi.—"It is better to trust in the Lord, than to put confidence in princes." Almost the last act of Frederick William's political life has a special bearing upon British history. Negotiations were carried on by him with William of Orange (afterwards King William III.), which led to a promise of active co-operation—"in the interest of the Protestant party in England, and of the liberties of that country," as in the words of one of the elector's despatches. It was stipulated also that Marshal Schomberg should be allowed to quit the Brandenburg army, of which he was at that time commander-in-chief, whenever his services might be required by William.

The Great Elector's civil government became as famous in his day as his military exploits. We must deeply regret that, instead of fostering the remains of parliamentary life that existed in every part of his dominions, he sacrificed them unrelentingly to his one supreme object of state-unity. The *Stände*, or provincial parliaments, consisting everywhere of the representatives of the nobility, of the burghers, and of the peasantry, were deprived, both in Brandenburg and in Prussia, of their inalienable right of voting the supplies. Their resistance was so rudely coerced that (if we pass in silence some futile attempts on their part in the following reigns to regain their lost prestige) we may date the beginning of absolutism in Brandenburg and Prussia from his days,—an absolutism that remained unbroken, or nearly so, until its hold was relaxed in the middle of the present century, when we may hope to see a stronger union of the sovereign and his people, cemented by the free participation of the latter in the rights as well as the duties of citizenship. Frederick William abandoned the old system of military levies and conscriptions in his own states, thus reserving for the use of his country all hands available for cultivation and for trade. His unremitting attention to the different branches of his army, and his wise economy, enabled him, with comparatively small pressure on the finances of his country, to raise the military establishment to the number of 40,000 as effective soldiers as any in Europe. The distribution of taxes was effected more equitably. His own farms were managed with an eye to improvement of every kind. He received with open-handed hospitality a great number of French Protestants driven from their homes by the revocation of the Edict of Nantes, and found himself richly rewarded by the industrious habits and the skill of these new inhabitants. Every active employment in agriculture, in trade and commerce, in arts and sciences, met with encouragement. He ventured upon the foundation of colonies on the coast of Africa, for the defence of which he kept up a small fleet of armed vessels. He was a staunch adherent of the Protestant faith, of which his wife, the pious Louisa Henrietta, was a bright ornament, and he promoted school-education and literature in every way.

We have thus arrived at the close of the first period of Brandenburg history. From a small nucleus of some thousand odd square miles, a firmly-organized state of European importance had arisen, of nearly 50,000 square miles in extent, and with a population of a million and a half. A short summary of dates may serve as a retrospect of this gradual and almost uninterrupted progress:—

About 500.	Immigration of Slavonic tribes.
925.	Henry I. of Germany subdues the Wends west of the Oder; conquest of their city of Brandenburg; foundation of the North March.
1136 to 1320.	*Ascanian Markgraves of Brandenburg.*
1157 to 1170.	Albrecht the Bear.
1230 to 1283.	Conquest of Prussia by the Teutonic Knights.
1324 to 1373.	*Bavarian Markgraves of Brandenburg.*
1356.	Brandenburg becomes an Electorate.
1373 to 1415.	*Luxemburg Electors of Brandenburg.*
1410.	Defeat of the Teutonic Order at Tannenberg.
1415.	Frederick, Burg-graf of Nürnberg, raised to the Electorate of Brandenburg.
1415 to 1701.	*Hohenzollern Electors of Brandenburg.*
1415 to 1440.	Elector Frederick I.
1440 to 1470.	Elector Frederick II.
1466.	The Teutonic Order loses Western Prussia, and keeps Eastern Prussia as vassal of Poland.
1470 to 1486.	Elector Albrecht Achilles.
1486 to 1499.	Elector John Cicero.
1499 to 1535.	Elector Joachim I.
1511.	Albrecht of Hohenzollern-Culmbach, grand-master of the Teutonic Order.
1535 to 1571.	Elector Joachim II.
1539.	Lutheran Reformation in Brandenburg.
1562.	Co-infeftment of Joachim II. for Prussia.
1571 to 1598.	Elector John George.
1598 to 1608.	Elector Joachim Frederick.
1608 to 1619.	Elector John Sigismund.
1613.	The Elector joins the Calvinistic Church.
1618.	Union of the Duchy of Prussia with the Electorate of Brandenburg.
1619 to 1640.	Elector George William; Thirty Years' War.
1640 to 1688.	Frederick William the Great Elector.
1648.	Peace of Westphalia.
1657.	Treaty of Wehlau; Eastern Prussia is freed from its vassalage to Poland.
1675.	The Swedes routed at Fehrbellin.

Prussia a kingdom. Frederick I.

We have seen that the uppermost principle in Frederick William's political life was to raise his state into a position as independent as possible of the Hapsburg-Luxemburg family, who, filling as they did the imperial throne of Germany, seemed nevertheless deaf to all but purely dynastic interests. It was with this same view that Frederick, his son and successor, laboured to raise his extra-Germanic possession, viz., the duchy of Prussia, into a kingdom. After endless negotiations, and the application of munificent bribes at the court of Vienna, the emperor at last, desirous of securing Frederick's well-drilled battalions, assented to his demand. In the year 1701, on the 18th of January, this new European monarchy was ushered in by Frederick's placing the royal crown on his head at the principal church of Königsberg, the capital of Prussia. Not averse to regal pomp and the splendour of courts, Frederick I. on that day established the new order of the Black Eagle, which holds the first rank among the decorations of the state, and is bestowed but sparingly. The promise given to the emperor, of assistance in the forthcoming war, was faithfully kept. Frederick drove the French from their positions of Kaiserswerth and Rheinberg, on the Nether Rhine, and strenuously assisted the Duke of Marlborough in the reduction of other places. His youthful and brilliant captain, Prince Leopold of Dessau (celebrated in much later years as "the Old Dessauer"), led the Brandenburg-Prussian soldiers into Bavaria, where a terrible army had assembled under the French general Villars. Here it fell to their honourable lot to fight under the eyes of Marlborough and of Eugène of Savoy, and to take their due share in the labours and the glory of the great day of Blenheim. It is reported that, when in the very centre of the position the ranks of the allied army had been three times broken, the Prince of Dessau led his grenadiers onward single-handed, and decided the day. The same intrepidity was evinced, and the same success obtained, by the Prussians in the Italian campaign, when Leopold Dessau, under the command of the great Eugène, was the first to storm and to carry the ramparts of Turin, in the battle of the 7th of September 1706. They did acceptable service also in the battles of Ramillies (in the same year), of Oudenarde (1706), and of Malplaquet (1708).

Frederick William I.

Frederick I. left his kingdom in 1713, not inconsiderably augmented by heritages and peaceable acquisitions, to his son Frederick William I., by his second wife Sophia Charlotte of Hanover, sister of our king George I., and the friend and correspondent of many of the first savans of her day. Yet neither the father's taste for the pomp and ceremony of royalty, nor the philosophic elegance of Sophia Charlotte seems to have been inherited by this sturdy prince, who was given to his country to prepare it, during twenty-seven years of unremitting labour (1713 to 1740), for the rough handling it was to go through under the succeeding reign. His name has been handed down to history as that of a mean niggard, of a ridiculous drill-sergeant, and of a cruel, half-mad barbarian. It would be impossible to deny either his parsimony, or his military propensities, or his severity and occasional bursts of impetuous rage. But we are inclined to look more leniently upon parsimonious habits in a king when they are extended to his own requirements as well as those of others, or upon outbreaks of ill-suppressed anger when this anger is the effect of a desire for the *salus rei publicæ*. We would forgive the Prussian grenadiers their faultless regularity, and even the monstrous size of a regiment of giants, when we know that their commander never abused this terrible armament for deeds of aggression and conquest. Punctuality, frugality, and order became through him the rule and heir-loom of his country; the expenditure of an army of 72,000 men pressed not a whit heavier upon its resources than half as much had done under his father's less careful government; and a well-filled and well-guarded treasury secured the means of prompt action in a country of undeveloped resources, and in an age when the improved principles of national economy were unknown. The population of the country made rapid progress, and was increased by a carefully-encouraged immigration, chiefly of Protestants, who had been thrust out of their own countries by the bigotry of their masters. The king's own pleasures lay almost exclusively in field-sports, in parades, and in the company of his drinking and smoking associates (*tabaks-collegium*); and his contempt of books and book-learning went so far that, during many years, the annual expenditure of the royal library did not exceed one guinea for a charwoman's occasional scrubbing of the staircase. Yet he gave proper attention to the

Frederick II., or "the Great."

schools of the poor, and extended the parochial system by liberal endowments. He gave a wholesome stimulus to the prompt administration of justice. Trials for witchcraft were for ever abolished by him. Frederick William I. was ever unwilling to resort to arms. He obtained Gueldres in exchange for the principality of Orange, and held Stettin by a peaceable arrangement with Sweden, until Charles XII., on his return from Turkey, forced him to a trial of arms by the repudiation of this arrangement. Charles XII. in this conflict narrowly escaped being taken prisoner in the fortress of Stralsund, and the King of Prussia remained in undisputed possession of Stettin and the mouth of the Oder. In 1735 he assisted Austria with 10,000 picked men in the war of succession in Poland, but withdrew his valuable assistance when he discovered that his confiding nature had been all along played upon by the court of Vienna, and that Austrian intrigue was at work on every point to oppose the interests of his country. This was the last time Frederick William drew the sword. The internal improvements of his dominions henceforward remained his sole object until his death, in 1740, when he left his kingdom, increased by nearly 5000 square miles of territory, and no less than 900,000 inhabitants, to Frederick, the eldest of his remaining sons. Frederick had never been his favourite. From the years of his boyhood, the heir-apparent seemed to possess none of those qualities which Frederick William respected, to the exclusion of almost all others,—viz., absolute obedience to the head of the family; attention to the prosaic part only of kingly business; scrupulous punctuality in military matters, rather than tactic and strategic ingenuity; strict and undeviating adherence to every dogma of the Calvinistic or "Reformed" Church; and, finally, violent contempt of all unmanly graces of social life, of literature and the fine arts, of foreign principles and manners. After the first attempts of imparting these principles had failed, it would seem that the king formed the resolution, for what he considered the preservation of Prussia from utter ruin, of cutting off the succession of the prince-royal, either by his voluntary abdication or by actual violence. Of the latter method, the world has been filled with accounts little creditable to the character of the stern and unbending father; to the former desire, when it dawned upon the prince's mind as a fixed purpose of his royal master, Frederick opposed this characteristic answer:—"The king evidently wants me to abdicate; I will renounce my right of succession on condition that my father declares I am not his rightful son." The effect of this terrible and cruel apprenticeship on the crown-prince's mind is clearly and tragically perceptible, in the gradual change from a soft, most charming, most affectionate, and open disposition, to that character which his unworthy friend Voltaire describes as "poli et dur comme le marbre;" that coldness which wounded the enthusiastic tenderness of his beloved sister Wilhelmina; that expression of stern melancholy which settled on his brows and marred every enjoyment, even that of his later triumphs; that measured and rarely genuine submissiveness with which he met his father's advances when a reconciliation had taken place. He never lost his true attachment to poetry and the fine arts; or, what is more, his attachment to tried friends, among whom the two Scotchmen, the Lord Marshal Keith and his brother James, held a prominent place to their respective deaths. But his existence remained cheerless,—illuminated with but few rays of light,—devoted to a continued struggle with the difficulties of a government, the responsibility of which he took entirely upon his own shoulders, or of foreign wars which he had commenced in the full flush of youth and wealth, and which must have worn out any but his mind and body, when the continent of Europe combined to chastise his rashness. Beloved in his early youth, feared in his manhood, admired in his old age, he has now recovered in the hearts of his people that intense affection which his youth had inspired; and whilst Europe calls him "the Great," he lives among the Prussians as their "Old Fritz," or as Friedrich der Eingige (the Unique). None of the succeeding sovereigns of Prussia have ventured upon taking, at the time of their accession, the name of Frederick III.

Born 24th January 1712, Frederick was very soon subjected to a strict *régime*, every detail of which had been minutely prescribed in the autograph instructions of the king himself. Contrary to the royal expectations, the boy took to flute-playing, French wigs, and French books, instead of drilling, the grenadier's pigtail, and the catechism. Before long, the headstrong will and rather flighty disposition of the crown-prince, encouraged by unwise associates, by the indulgence of his mother, and by the affectionate caresses of his sister, led to violent altercations with the king, who, likewise urged on by evil councillors, believed that he saw the entire fabric of his state undermined and crumbling into dust by this apparent conspiracy among his own family. Driven to despair by threats and insults, and by the galling sense of constant espionage around him, Frederick resolved to flee from the presence of his father. Several schemes were formed and rejected, when at last, the occasion of a journey to Southern Germany with the king appearing favourable, every preparation was made for a flight to France and thence to England, where he hoped to find an asylum with his mother's brother, King George I. But his guardians kept too close a watch; and the unfortunate youth's chains were rivetted all the faster for his rash attempt at desertion. The king declared his resolution that the young captain must be tried by court-martial, and suffer the penalty of death like any other deserter. In vain did many of the sovereigns of Europe interfere with the modern Brutus in behalf of the crown-prince; among them the Emperor of Germany, whose paid agents in Berlin had contributed but too much towards the embitterment of this animosity. It would appear that the court of Vienna thought of preventing, by means of this family disunion (which they actually did), the intended marriage of Frederick with a daughter of George II., which would certainly have been the result of a reconciliation. A close confinement at the fortress of Cüstrin was the only alleviation to which the king would at last consent. On quitting this, the royal prince was ordered to remain at the town of Cüstrin, and to give his whole mind to the details of state finances and civil government in general. The young man's stubborn mind was curbed, and although with no good grace did he apply himself to these uncongenial labours, yet he frequently reverted in after years with gratitude towards his rude taskmaster, as having laid the foundation of his skill as a governor of the country. In this state of utter prostration and subjection, he was commanded in 1733 to marry a princess of Brunswick, whom he had never seen, and never (it is believed) could have liked. As he would have complied with any command, sullenly but submissively, he married the handsome but insipid princess, in whose praise it must be said that she bore her husband's polite neglect uncomplainingly, and without bitterness of heart. At a distance from the court, although outwardly reconciled and scrupulously attentive to his duties as district-governor and as colonel of a regiment, the prince resided at Rheinsberg during the remainder of the king's life, surrounded by friends of his own choice, and devoted to literature. To this he contributed, among others, a curious treatise called *The Anti-Macchiavel*, in which violent protests are raised against the dishonest principles of the great Florentine master of statescraft.

On his accession to the throne, 31st May 1740, he retained for the most part the wise and salutary enactments of his father, but freeing them from many of their asperities,

History.

and instilling new life into them. His prodigious activity made itself felt very soon in every department of his administration. The Potsdam regiment of giants was disbanded, and the fighting strength of his army increased. Frederick abolished the rack, simplified the procedures in courts of law, admitted every petitioner to his presence, and declared in his own pithy manner that, in his dominions, everybody should attend to his own soul as he pleased ("Ein jeder kann nach seiner Façon selig werden"), by which perfect religious liberty to all religious denominations was established in Prussia, before any other country.

The death of Charles VI., Emperor of Germany, in 1740, without male issue, opened the flood-gates of political intrigue and ambitious designs. Instigated by France, the Bavarian elector laid unjust claims to Austria proper, leaving to the emperor's only child, the beautiful and virtuous Maria Theresa, nothing but the kingdom of Hungary. The Saxon elector's equally doubtful claims were on Moravia. Frederick II. of Prussia considered the event a favourable opportunity for seizing by force what had been unjustly withheld by Austria from his predecessors since the Thirty Years' War,—viz., the Silesian principalities of Liegnitz, Wohlau, and Brieg. Those predecessors had never desisted in their efforts to obtain them. Devolving by right of inheritance to the Hohenzollern family in 1675, they had been retained, as we have seen, by the then emperor for the augmentation of his own family property. Frederick I., like the great elector, had protested against this, declaring in a state paper,—"As for keeping my word, I must, I will, and I shall do it; the task of enforcing my claims on Silesia I leave to my successors, whom, under these circumstances of injustice, I cannot and will not in any way bind." And Frederick William I. had, on a recent occasion, expressed the hope, "that there stood the man," pointing to his son, "who would revenge the indignities that his house was suffering." Frederick II.'s demands were no sooner despatched to Vienna, than he marched across the frontier of Silesia with 30,000 picked men. Queen Maria Theresa very naturally rejected the demand thus impertinently proffered. But her long-neglected though numerous army proved deficient in every respect. Frederick had the rare good fortune of being permitted to combine his strategic book-learning with a knowledge of the realities of war in a uniform continuance of success, for which he was at first indebted mainly to the perfect organization of his soldiers, and to the leadership of the Prince of Dessau, whom we saw fighting in the battles of Marlborough, and of Field-Marshal Count Schwerin. The latter was a Pomeranian nobleman of high descent, whose great military ability and moral worth Frederick ever appreciated to their full value. Two great battles—of Mollwitz, A.D. 1741, and of Chotusitz, in the following year—mark this his first campaign, which terminated in the peace of Breslau. Nearly the whole of Silesia was delivered into his hands. The numerous Protestants of Silesia hailed their deliverance (as did likewise many years after the Jesuit order, to whom the king gave free access to his dominions, when the indignation of Roman Catholic courts and nations had driven them forth into banishment). Two years after the peace of Breslau, in 1744, Frederick occupied the important country of Ostfriesland, on the German Ocean (at this day incorporated with Hanover), which had fallen to his inheritance by the demise of the last of its princes. But meanwhile the strenuous exertions of the unfortunate Maria Theresa to raise up a Christian European coalition did not allow him to remain inactive. Frederick had declared in favour of Charles, elector of Bavaria, as a candidate for the vacant imperial throne, in opposition to Maria Theresa's amiable husband, Francis of Lotharingia. Accordingly, the former was elected emperor, under the name of Charles VII., by the German Reichstag or Diet, and Frederick, on the strength of an alliance with him and with the King of France and others, opened the second campaign in Silesia in the month of August 1744. Not so uniformly successful as in the former campaign, he yet showed the superiority of his army and of his own ripened military genius by three brilliant victories. At the close of these two first campaigns, which are known in military history as the Silesian wars, Frederick had lost almost every grenadier of his father's training, and spent every thaler that had been collected in his father's treasury. Charles VII. was dead; his rival of Lotharingia (the ancestor of the present Emperor of Austria) had been proclaimed German emperor; and Frederick now acknowledged him in the treaty of Dresden, December 1745, which again confirmed him in the possession of Silesia. Whatever difficulties the course of events might bring, they would henceforward have to be met by the resources of his own mind alone. Although he may never have anticipated to the full the terrible dangers that were destined soon to environ him on all sides, he strained every nerve to make good the years of peace and tranquillity allotted to him. The revenues of the country were increased by financial reforms, which, though very far indeed from being faultless in the light of improved science, yet were calculated to press but lightly on the productive powers of his country. Every encouragement and every device was resorted to in order to develope these productive powers. Whilst instilling new vigour into every branch of his multifarious administration, and also attending with all the zest of early manhood to the enjoyment of literature and of the society of his personal friends, he did not forget to collect, equip, and exercise an effective army of no less than 160,000 men, in the hope, perhaps, of thus preventing his enemy from further attempts to recover her lost province. But a will as energetic as his own lived in the much-tried empress. A formidable coalition between Austria, Russia, and Saxony, which was soon joined by France and Sweden, crowned her untiring exertions. A partition of the Prussian monarchy was the object of this alliance, which promised France an approach to the Rhine, and Russia the possession of Prussia proper, and was to reduce Frederick to the rank of Marquis of Brandenburg. To these secret negotiations Frederick was able to oppose but one alliance, which was destined to become not only most important for him, but also most auspicious as a precursor of repeated and, as it would seem, lasting bonds of amity, viz., with Great Britain. In January 1756 a treaty was signed by both parties for the avowed purpose of "repelling foreign invasions on German soil." Fortunately for Frederick, the treachery of a clerk in the foreign office at Dresden soon disclosed to him the secret transactions of the coalition. He knew from good sources of information that Saxony, in pursuance of the articles of treaty, was filling a camp at Pirna with troops. Unwilling to give his enemies the advantage of further preparations, he left his capital in the autumn of 1756,—not to return for full seven perilous years,—and suddenly appeared before Dresden at the head of 70,000 men. To the astonished world he gave full explanations by publishing *in extenso* the documents in his possession. As for Saxony, it soon became evident that he was resolved, as far as in him lay, to make her fertile plains his centre of operations, and to save his own country as much as possible from the miseries of war. In this plan, carried out with incredible tenacity throughout all the vicissitudes of the war, lies the secret of a fact that would otherwise baffle explanation, viz., that at the close of a protracted warfare, in which Prussia was the chief actor and the sole prize, this country was found to have suffered less in its resources than others of the contending parties. Very few of the battles were fought on

First Silesian war.

Second Silesian war.

Seven Years' War.

Prussian ground: like lions at bay, he and his gallant allies, ever alert on the frontiers, caused the hostile armies to halt in their onward marches that converged towards Berlin from the south, west, east, and north. The aid of Great Britain, both in money and in men, was at first hesitatingly and insufficiently bestowed, but after the battle of Rossbach, in November 1757, large subsidies and an efficient force were willingly granted, and with such unbounded confidence that the king was requested to give to the latter a general of his own choice. This alliance was abandoned by the English court soon after the accession of George III. in 1761, and Frederick was left to cope single-handed with difficulties which were just then of the most crushing nature. Of this memorable contest, which raised Frederick to a post of honour among the great generals of all ages—which brought to light unknown qualities of noble endurance and perseverance, not only in the great leader, but among his people at large—which disclosed the rottenness of nearly all continental states that had not undergone the Spartan training of so severe a taskmaster as Frederick William I.: of this war, a fuller account has been given in another part of this work. We purpose to pass its romantic vicissitudes in rapid survey, pointing to its features rather than to its strategic details. We have already mentioned his sudden march on the capital of Saxony. Dresden was occupied without resistance; the Saxon troops that had collected in the camp of Pirna were inclosed and forced to surrender *en masse;* and, pushing on to attack one of the two Austrian armies before their union, he was led into the most perilous and sanguinary battle of Prague, May 6, 1757, which, but for the heroic devotion of Marshall Schwerin, must have been lost. "The day is ours," exclaimed the king, "but 10,000 of our men are no more, and Schwerin, alas! whom I reckon another 10,000." But his position in Bohemia was lost by the terrible defeat of Kollin; his British and Hanoverian allies were likewise overpowered by the French; and, to make the list of disasters complete, a victorious advance led the Russian generals to Königsberg, where (as the wont is of Russian generals) the province of Prussia was by them, not long after, simply declared to be henceforward an integral portion of the Russian empire. Frederick, who had left his retreating troops in Silesia, joined another detachment of his army which was vainly endeavouring to stop the mighty advance of the French in Saxony. No sooner, however, had the French general, Prince de Soubise, completed (as he thought) the blockade of his enemy by the River Saale on the 5th of November 1757, than Frederick's cavalry and infantry, suddenly descending in an attack of unprecedented hardiness, soon covered the extensive plain of Rossbach with the flying remnants of an army that had been three times as numerous as his own. Not until the wars of the French Revolution had re-established the prestige lost on this famous day did the memory of its shame cease to rankle in the French army. To Frederick the victory of Rossbach gained a far greater accession of fame and power throughout Great Britain and Germany, than ever so many successful exploits against the Austrians could have accomplished; he was regarded in Great Britain as the hero of Protestant independence, and by Germans as their champion against the great invaders of the West. The same year (1757) saw Frederick victorious against the Austrians, commanded by their best general, the cautious and calculating Daun, in the battle of Leuthen, which, fought as it was under every disadvantage of number (in the proportion of 1 to 3), of quality of men, and of place, has ever been considered as among the strongest proofs of a rare strategic genius in the commander, and of the firm enthusiasm of the Prussians fighting under his banners. Both were signally exemplified again in the following (third) year of the campaign (1758), in which Frederick chastised the Russians near the village of Zorndorf for their insolent pillage and spoliation of the country. But soon other and higher qualities than military insight and enthusiasm had to be brought into action by king and people; and it is in these sombre days of adversity which lasted (although not unbroken by brilliant achievements) until 1762, that Frederick I. rises before us in full relief of heroism. Frederick was a great man by a quality which places him infinitely higher in our eyes than that mighty Corsican conqueror who has since been seen standing before his tomb at Potsdam in 1807; and that quality is his entire and absolute devotedness to his country alone. For him the government of Prussia ever appeared as a duty,—the existence and destinies of Prussia as a sacred trust. In this subjection of his individual will and whole existence under a higher and ideal sense of duty, this "chief servant of the state," not in words only, but in reality, stands far above the class of adventurers in the history of the world who sought their own rather than their country's good, and to whom even the throne was a seat of power and of wealth rather than of duty. An autograph letter addressed to his minister of state, Count Finckenstein, containing secret instructions, has been published lately. Its orthography, it is true, is even worse than in other French compositions of his pen, but every word in it is inspired by a patriotism of the highest order. "S'il arrivait," says the king, "que je fusse tué, il faut que les affaires continuent leur train sans la moindre altération et sans qu'on s'aperçoive qu'elles sont en d'autres mains; et en ce cas il faut hâter serments et hommages tant ici qu'en Prusse et surtout en Silésie. Si j'avais la fàtalité d'être pris prisonnier par l'ennemi, je défènds qu'on ait le moindre égard pour ma personne, ni qu'on fasse la moindre réflexion sur ce que pourrais écrire de ma détention. Si pareil malheur m'arrivait, je veux me sacrifier pour l'Etat et il faut qu'on obéisse à mon frère, lequel, ainsi que tous mes ministres et géneraux me répondront de leur tête qu'on n'offrira ni province ni rançon pour moi et que l'on continuera la guerre en poussant ses avantages tout comme si je n'avais existé dans le monde."

The series of disasters between Frederick's victories of Leuthen and Zorndorf and the year 1762 was, as we said before, not without successful interludes, such as the day of Minden, in 1759, by which Prince Ferdinand of Brunswick (the commander whom Frederick's choice had placed at the head of the Hanoverian auxiliaries) drove the French army to seek shelter beyond the Rhine; or the days of Liegnitz and of Torgau, in the same year, under the personal command of the king. But the peril now assumed huge dimensions, and that web was drawn closer and closer which was to stifle the inconvenient, *parvenu* state of Prussia. The Austrian troops were at this time admirably commanded by Generals Daun and Laudon, and fought with genuine attachment to the cause of their empress. In France an able and active minister, Count Choiseul, had succeeded a rule of favouritism in the king's councils, and though public opinion in France expressed itself more strongly every day in favour of Frederick, the numbers and efficiency of the armies sent to annihilate him were greatly augmented. In Russia a strong determination prevailed at the court of the Empress Elizabeth to erase the memory of Zorndorf, and to leave Prussia proper, and possibly more, as a lasting heirloom to the czars of Russia. Spain, towards the close of the period we are speaking of, and even the Pope himself, joined the ranks of his adversaries. To this host, ever growing, as was feared, in energy and numbers, Frederick had to oppose an army consisting more and more of raw recruits, and an empty exchequer, which levies and contributions in the enemy's land lost all power of filling. Lastly, as if to try his powers of endurance to the utmost, his sole ally Great Britain, under the Earl of Bute's administration, left him to his own resources in the hour of his greatest need, A.D. 1761, and withdrew from the war altogether. Frederick's iron will was not to be crushed with adversity; fighting and retreating, or collecting occasionally his army behind unapproachable lines of defence, which his genius in fortification understood how to raise up in forty-eight hours; losing armies and replacing them; never a moment without cares but rarely oppressed by them;—thus the invincible hero struggled along through upwards of three years of disappointment and defeat. He reposed a hearty confidence in his generals (his brother Prince Henry, the Prince of Dessau, Seydlitz, Ziethen), but appeared among them to take the lead in the great and decisive actions. We name the series of lost battles from 1758 to 1761, to show the destructive character of some of them. On the 14th of October of the former year a grand night-attack on his camp at Hochkirch, executed with admirable precision by the Austrians under General Daun, deprived the king of many thousand soldiers, and "of all his guns and ammunition." The next year (1759) saw the most terrible of slaughters in the two days' battle of Kunersdorf, against a combined army of Russians under Soltikoff, and of Austrians under Laudon, which cost him more than half of his effective army, and again "nearly all his guns;" and must have cost him his capital, had not the jealousy of his antagonists prevented the execution of Maria Theresa's orders. First one and then another of his generals were forced to surrender to overwhelming forces; and thus the greater part of Saxony, and all his positions in Silesia, had to be abandoned. The day of Liegnitz saved a few of the latter, and that of Torgau many of the former. Nevertheless his situation improved but little. Daun in the heart of Saxony, and Laudon in the heart of Silesia; the Swedes masters in Pomerania, and the Russians in Konigsberg; 150,000 French on the right bank of the Rhine; the whole of Europe (without exception) united against him or sullenly neutral;—such was the position of affairs on the 5th of January 1761, when the accession of Peter III. to the throne of the czars suddenly transformed a formidable adversary into a useful ally. Unfortunately for Frederick, the life of his eccentric admirer was soon cut short by high-born assassins. But Peter's widow and successor Catherine, although her first acts were hostile to the king, soon relented in her antagonism, and this from a motive which deserves mention—namely, that letters were found in her murdered husband's portfolio in which King Frederick had seriously and repeatedly urged Peter to change his conduct towards the amiable empress his wife. The friendship, and afterwards the neutrality of Russia, coupled with the withdrawal of Sweden from the coalition, rendered Frederick's action unfettered in the north. His generals, victorious everywhere against the non-Austrian troops of the empire, caused one after the other of the German princes to raise loud solicitations for peace at the court of Vienna, and finally to abandon the cause of Austria. The "first military nation of Europe," France, looked with disgust upon the continuance of a war which brought ever fresh humiliation, at the hands of Prince Ferdinand of Brunswick, upon her once so glorious banners. Half broken-hearted with despair, Maria Theresa had vainly hoped that her field-marshals would recover their laurels, lost again and again at Burkersdorf and at Schweidnitz (1762). The cry of Europe became too loud; her own finances were ruined beyond repair—her resources drained to the last; Maria Theresa consented first to an armistice, and then, with long and wailing protestations, to the acknowledgment of Frederick as lord of Silesia in the peace of Hubertsburg, February 21, 1763. It is a characteristic and encouraging sign of the age in which we live, that when in 1856 a proposal was laid before the present King of Prussia, Frederick William IV., for a series of commemorations to be celebrated on each succeeding anniversary of the victories and glorious events in the Seven Years' War, his majesty wrote the following words on the margin of the paper: "With my consent, none of these anniversaries shall be celebrated in Prussia, save and except the 21st of February 1763."

Prussia had now attained a place among the great powers of Europe,—an envied and hazardous position which the scanty natural resources of the country could (and can to the present day) but ill support, without the unremitting attention, real wisdom, and rigid economy of her rulers; without willingness to sacrifices and self-devotion among well-governed and contented subjects; and without the respect of civilized Europe towards the onward mark of mental and moral culture within her dominions. Frederick's labours of peace during the rest of his life, from 1763 to 1786, were unremitting. He applied himself, with the applause, and with the willing support of his people, to the removal of every vestige of the war. His private expenses were moderate: "an absolute king," he said, "is the poorest man in the state; for whilst his subjects can spend their own as they please, he alone must feel in every trifling expenditure that so many thalers are withdrawn from application to matters of public utility." A code of laws, the present Landrecht of Prussia, was prepared (although not published in his days) by his chancellor, Count Karmer. To assist in the improvement of agriculture in his dominions, the king, much interested by Arthur Young's writings, sent over young men to study British husbandry. He attracted, by the bestowal of bounties and privileges, the immigration of many thousands of colonists who seemed likely to introduce improved methods of farming. He filled deserted villages, and built up such as had been destroyed; he opened his well-filled military granaries, founded societies for facilitating loans on deposits and on land, granted temporary freedom from taxation where most needed, and gave occupation to idle or weak hands, by encouraging the manufacture of home-grown silk. Large tracts of bog and morass were reclaimed at great expense; and the country was covered with a net-work of canals. His financial measures were manifold and ingenious, although frequently of so complicated a nature, and (according to our present views) so unsound, that many of them, instead of lightening the burden of the people, acted most oppressively. His *regié* or system of indirect taxation, copied from the French, and entrusted to a host of French place-hunters; his prohibitive duties, and his monopolies, were so many infractions of national well-being, although they filled the coffers of the state in an unprecedented degree. By them, in conjunction with this rigid economy, he was enabled to keep up an effective army of 225,000 men, and to leave to his successor a treasury filled with nearly L.11,000,000 sterling. Many other prejudices of his age, besides the financial ones, did he retain to the last; not all of them as harmless as his dislike to good roads, "by which *he* did not mean to facilitate an enemy's advance in his country," or as silly as his aversion for all offices of state, or in the army, to men of noble birth. The one among his prejudices which has acquired most notoriety, is the subserviency of his mind and manners to French tastes, in language and literature, in many of the chief transactions of the state, and alas! in the terrible obstinacy with which he opposed his reasoning to most of the fundamental doctrines of Christianity. Filled in his early days with dislike to the dogmatic and unedifying religious instruction of his father's chaplains, and then bound up in close literary friendship with Voltaire, he, although a Protestant, assimilated his own views to those of the Frenchman, for whose irreverential sarcasms an excuse (if any were possible) might at least be found in the horrible superstitions and refined mystifications of the Jesuits, then reigning paramount at the court of France. Frederick, it is true, was ready to acknowledge and to honour the serious convictions of others. History tells us that his truly pious comrade in arms, General Ziethen, never had to complain of railleries on his part. It is reported also that one morning, when the king heard a Pomeranian brigade marching towards its appointed post in the battle array, under the solemn sounds of one of those noble ancient hymns ("Gott des Himmels und der Erden"), all devoutly joining in the strain, his eyes filled with tears, and, turning to one of his generals, he said—"Ah, these troops must be invincible!" Yet, into the ferment and turmoil of his soul none of the soothing comforts of religion was ever seen to enter. A true and often gentle friend of his companions, and devoted to his country, for which he was ready to give up his life-blood, he yet enjoyed not the peace of God, which passeth all understanding.

A few words on the prominent events of these years of peace (1763 to 1786) will rapidly lead us to the reign of the next king. Frederick II. joined Russia and Austria in the first partition of Poland, A.D. 1772,—a miserable expedient, in which the Emperor Joseph's as well as his own main purpose seems to have been, to prevent Russia from taking the whole instead of the lion's share of territories so dangerously contiguous to their own capitals. By this partition the king obtained Western Prussia, which the Teutonic order had lost, as we have seen, to Poland in 1466, and some fertile, already semi-German districts on the River Netz. In all, the increase of territory under Frederick's reign, by conquest, inheritance, or otherwise, amounted to 29,313 square miles; the population of the monarchy at his death numbering five and a half million souls. The last act of his political life was the formation of a German league of princes (Deutscher Fürstenbund), intended to prevent the renewal of attempts such as Joseph II. had twice made during the last years,—viz., of incorporating Bavaria or other German states with the vast possessions of the Hapsburg family.

Frederick-William II.

Frederick-William II. disappointed the hopes that had been entertained of him in his uncle's lifetime and on his accession. The long habit of absolute command, and the absence of tender and soothing influence upon a solitary life, had rendered Frederick peevish, capricious, and tyrannical in his latter years, and the exactions of his French excise and custom-house officers embittered large classes of the community. The new king's accession was therefore looked upon with much favour, a feeling which greatly increased when the French excisemen were ordered out of the country, the *regié* superseded, and other burdens removed. Soon, however, the apathy of Frederick-William, his grossly licentious habits, his carelessness of money, his intolerance in religious matters, and, more than all, the serious blunders of his foreign policy, weakened his influence at home and abroad. His army, under Duke Ernest of Brunswick, succeeded with ease in re-establishing the ascendancy of the House of Orange in the Dutch republic against the wishes of that people. Another armed intervention, purposing to prevent Russian and Austrian aggressions against Turkey, had no other result but the exhaustion of his treasury. Urged on by Russian influence, the king promised Austria his support (during a meeting with the emperor at Pillnitz, A.D. 1790) towards the restitution of royal power in France. He accordingly invaded that country with a powerful army in 1792, much against the inclinations of his own people. This invasion hastened the downfall of monarchy in France and the destruction of the royal family. Besides, all military advantages of the campaign were soon lost by an ignominious retreat after the resultless cannonade of Valmy. The shame of Prussia became still more appalling when, after two years of alternate victory and defeat, she admitted the very same republicans of France, against whom that war had solely been directed, to friendly negotiations, and secretly promised them the cession of all lands on the left bank of the Rhine, stipulating for herself and the rest of North Germany absolute neutrality during the forthcoming wars. This was accomplished in the disgraceful treaty of Basle, A.D. 1795. In the Polish difficulties of his reign, Frederick-William's policy, though more successful than on the Rhine, was equally unscrupulous and dishonourable. Poland, at first and during several years his ally, was abandoned by him to Russian encroachment, and then subjected to a second (1793) and a third, final, partition (1795), Prussia's share in these successive plunders consisting of nearly 38,808 square miles of land.

Frederick-William III.

Frederick-William III. succeeded his father A.D. 1797, at a time when religious intolerance and the restrictions exercised against the liberty of the press had spread the seeds of disaffection throughout the country. The moral rectitude, the simplicity and purity of manners, the earnestness of purpose in the youthful king, and the uncommon loveliness of his queen, the Princess Louisa of Mecklenburg-Strelitz, soon restored to the throne the full attachment of the people. His father's hateful edict against dissent, and others instituting a censorship of all printed publications, were speedily rescinded, and the government entrusted to men of tried virtue. Every exertion was made to pay off a debt of L.3,300,000 which Frederick-William II. had bequeathed instead of a well-filled treasury. The king turned to the best account the neutrality which the treaty of Basle imposed upon his states, by attention to peaceful improvements. In the year 1801 the secret stipulations of that treaty were carried into effect in the peace of Luneville; France definitively obtained the king's possessions on the left bank of the Rhine, and Prussia was "indemnified" in 1803 at the hands of the German empire, and at its expense, by a considerable accession of territory, which increased the bulk of her dominions by 4116 square miles of admirably-situated land. But this neutrality did not long protect Prussia from aggression. Our readers will remember the Franconian principalities of Ansbach and Baireuth, which were described above as belonging to a branch of the Hohenzollern family, cousins of the electoral and royal line. These principalities had become a royal possession in 1791. Through that territory Bonaparte ordered a portion of his now imperial army to pass on their march towards the Austrian frontiers, A.D. 1804. In vain did Frederick-William III. remonstrate against this violation of neutrality. He now reluctantly gave ear to the counsels of the war-party at court, which included among its numbers some of the best men of his day,—Barons Stein and Hardenberg, &c., supported by the chivalrous Prince Louis Ferdinand and by the queen herself. The emperors of Russia and Austria prevailed by their entreaties in 1804. Prussia secretly joined the coalition, but was prevented from active co-operation by the conclusion of peace which immediately followed the irreparable defeat at Austerlitz, December 2, 1805. The crafty Corsican induced the king's plenipotentiary, Baron Haugwitz, to accept Hanover in exchange of Ansbach, Baireuth, Cleves, and Neufchatel; which last-named principality, situated on the frontiers of Switzerland, had become a Prussian heirloom in 1707. So great was the terror of Napoleon's name that this base scheme of robbery against the King of Great Britain was ratified and actually carried into effect by Frederick-William III. The insatiable desire after territorial aggrandisement, without regard either to treaties or to old alliances, was soon to receive a salutary chastisement at the hands of the principal accomplice. Swollen in size to 135,545 square miles,[1] or nearly fourteen times as large as the first Hohenzollern Kurfurst had ruled over, Prussia miscalculated her natural power. Napoleon, not satisfied with the advantages accruing to him from Prussia's conflict with Great Britain, insulted and humiliated wherever he could the king, whose character for honesty and fair dealing he had ruined by this complicity. If Frederick-William had decided upon war too late, his resolution was certainly a precipitate one in 1806. Negotiations having been broken off by Prussia, Napoleon hastened to attack her forces before further alliances could swell their number. The very first encounter, near Saalfeld, October 10, 1806, crushed the Prussian vanguard, headed by Prince Louis Ferdinand, who gallantly fell in this action. Four days afterwards, the fate of all the country between the Rhine and the Elbe was decided by the disastrous battle of Jena. The self-sufficiency of Prussian troops, drilled under Frederick II., but not commanded by his genius, received a severe lesson. No line of retreat having been marked out by the commander-in-chief, several detachments of the army were taken prisoners, and the whole country lay open to invasion, and was soon undefended even by fortresses, which overpowered by terror rather than by force, opened their gates to the enemy. The king withdrew far into Prussia proper. His ally, Alexander I. of Russia, attempted in vain to stop the onward march of Napoleon by the sanguinary battles of Eylau (7th and 8th February 1807) and of Friedland (14th of June). A personal meeting of the three sovereigns was arranged at the town of Tilsit, near the easternmost boundary of Prussia, which led to the conclusion of a most disastrous peace (9th of July 1807). Frederick-William lost all his possessions on the left bank of the Elbe (more than half of his kingdom), and was candidly assured that if he did not lose all instead, it was done out of deference to the Emperor Alexander's "wishes." Even this small remnant of territory was farther deprived of the duchy of Warsaw (now given to the King of Saxony), and of Dantzic, which was declared a republic; it was further made to raise war contributions to the enormous amount of L.22,500,000, was to pay for French garrisons in some of its fortresses, and to assist the emperor in all coming wars. And yet the prediction of that gallant Prussian, General Blucher, expressed on the morrow of the defeat at Jena, in his own uncouth language, that "matters would look up again soon, and that now more enlightened principles would put their foot into the stirrup," was fulfilled in a manner very creditable to king and country. A complete remoulding of the state commenced, proving the fallacy of the wide-spread opinion, that reforms must not be attempted in times of war and distress. Frederick-William, who, with his queen, made every sacrifice of royal state, and even common comforts, gave his confidence to Baron Stein, the best German statesman of the day, a man of high and noble birth and independent wealth, an upright, sagacious, and powerful reformer. The offices of state were simplified, the remains of feudal vassalage abolished, the sale and purchase of land set entirely free, many burdens raised that lay exclusively on the lower classes, the trades liberated from mediæval shackles, and the towns left to manage their own affairs without government interference. Stein was preparing a re-construction also of the ancient parliaments on a new basis of unity and equality, when the rage and threats of Napoleon forced him to resign his post in 1808, since when he became one of the prime movers of resistance against the usurper,—first in Austria, then at St Petersburg, and later again triumphantly in Germany. His work of internal reform was meanwhile carried on in his sense and with energy by Baron Hardenberg, the king's state chancellor. Laws were promulgated for the more equitable distribution of taxes and the abolition of privileges. Most of the civil disabilities of the Jews were abolished. In spite of the exhausted state of his finances, the king founded and endowed a university at Berlin. There was a new hope and cheerful energy called forth by these reforms in Prussia and throughout oppressed Germany. Young men of all classes quietly joined the few regiments which the treaty of Tilsit permitted Prussia to keep on foot, and as quietly left them after having undergone the necessary training and drilling; thus deluding the vigilance of French spies. Commissions in the army were given, without consideration of birth or lineage, to all duly qualified men of education. It was during these years of deepest humiliation that the plan of general armament was formed by Scharnhorst and others which came to light in 1813, and which has rendered Prussia one of the most powerful military countries, for defensive purposes, in the world. By this military institution, all young men from eighteen to twenty-six years old are expected to enter the ranks of the army during three years, such only being privileged to serve one year instead of three as give proof of a superior education, and are able to equip themselves. Between the ages of twenty-six and thirty-two the privates, sergeants, and officers thus trained are liable to be called out from their civil occupations in case of need. This is the First Aufgèbot, or levy of the landwehr. The second, consisting of men between thirty-two and thirty-nine, is subject to the same regulations, but only in case of great danger. Finally, a third Aufgèbot, called Landsturm, comprises all men above that age who are expected to fight only for the immediate defence of house and home during an invasion. It was known throughout the country in those years that the king would break the bondage as soon as circumstances admitted. He visited St Petersburg to prepare a defensive and offensive alliance in 1808, and took cognisance, though not ostensibly, of the secret "league of virtue" (Tugendbund) in which most patriotic Germans joined for the expulsion of their hateful oppressors. Still, however, he refrained from hostilities against Napoleon. It was ordained by Providence that the secret powers of nature, rather than the will of man, should break asunder the tyrant's colossal power. Repeatedly victorious against the court of Vienna in the campaign of Wagram (1809), and married to a "daughter of the Cæsars," Maria Louisa of Austria, standing, as it were, on the summit of his earthly glory, he was now thought to rest his feverish thoughts on the firm establishment of a hereditary empire in favour of his son, the King of Rome. Instead of this, he meditated an unprovoked attack upon Russia, and, inverting the direction of Attila's great migration of warriors thirteen centuries before, he swept the whole of trembling Europe with a host of half a million of men, to which even Austria and Prussia were constrained by treaties to add their quota. When the disasters of an early and terrible winter overtook his retreat from Moscow, and it was long before Europe was fully informed of the utter destruction of his army, the Prussian general York, who held a command on the French army's left wing in Kurland, was the first to see with his own eyes. Left without instructions from Berlin, he concluded an armistice with the pursuing Russians on the 30th December 1812, near the frontier town of Tauroggen, and speedily applied himself to the organization of a landwehr in Prussia proper (*i.e.*, the province of Prussia), assisted by Baron Stein and Count Dohna. On the 3d of February 1813 King Frederick-William, who had a short time before left Berlin, published an energetic decree calling his people to arms. In an incredibly short time the enthusiasm of the people not only filled the ranks of his army, but also contributed largely to improve the exhausted condition of his finances. An alliance was concluded with Great Britain and Russia, and a declaration of war issued on the 27th of March. Napoleon had lost no time in collecting an army far superior in numbers to the allied Prussians and Russians at that

---

[1] The present size of Prussia is only 111,154 square miles, or 24,391 less.

History.

time in the field. His first encounters, at Grossgörschen and Bautzen, with the raw battalions of his enemy were crowned with success, although his generals could well discern "le commencement de la fin." Even after Austria had joined her troops to those of Russia and Prussia, the first great battle of Dresden, August 26, 1813, again ended in a defeat of the allies. But meanwhile the Prussians had found time to increase and improve their armaments in a manner which deserves the admiration of all ages. Napoleon had the chagrin to hear of four considerable defeats sustained by his generals within eighteen days,—by Marshals Ney and Oudinot on their march towards Berlin, at Grossbeeren and at Dennewitz; by Marshal Macdonald on the banks of the River Katzbach in Silesia; and by General Vandamme at Culm in Bohemia. The last-named victory of Culm, gained principally by the admirable steadiness of the Russian guards, redounded much to the credit of the Prussian general Kleist, and even more to that of King Frederick-William himself, who had acted as commander-in-chief on the occasion, and without whose urgent personal representations the battle would never have been fought at all. The other battles at once raised the names of Blucher, York, Gneisenau, and Bülow to great renown. And now the crisis was fast approaching. On both sides all available forces were collected into a huge mass of combatants in the plains round Leipsic. On a number of adjoining but separate battle-fields the French army of 180,000, directed by Napoleon's iron will, fought with great intrepidity against nearly 300,000 enemies intent upon a final deliverance of Europe, on the 14th, 16th, 17th, 18th, and 19th of October. How great was the slaughter of those days may be measured from the fact, that the Prussian list of casualties alone showed a number of 14,000 killed. Napoleon at last was utterly defeated, and his army dispersed. Blucher, in advance of the other allies, followed its flight, and crossed the Rhine near Caub on New Year's-day 1814. When the diplomatic and military manœuvres of Napoleon threw confusion into the headquarters of the allied army, Blucher again resolved all difficulties by a daring march direct upon Paris. There, after a last bloody struggle on the heights of Montmartre, the cause of Europe was crowned with success by the occupation of the capital and the banishment of the usurper. King Frederick-William and Blucher, following an invitation of the prince-regent, came to England, and were received with great courtesy,—Blucher became, in fact, the hero of the day. At the Congress of Vienna, which assembled soon after, Prussia met with great opposition when she demanded for herself the whole kingdom of Saxony, on the ground of its having proved the most obnoxious to the cause of liberation. This demand, together with the divergence of opinion on the restitution of Poland, and almost every other point that required settlement, frequently endangered the temper of the congress to such a degree that Napoleon, founding his hopes on a general disunion, ventured upon a return to France. This immediately restored harmony and concord; Bonaparte, again the military master of France, but formally outlawed by Europe, was to be crushed without delay. The first in the field, favoured by geographical proximity, and still more by military readiness, were Great Britain and Prussia. Against the Duke of Wellington, therefore, and Field-Marshal (now Prince) Blucher, the army of Napoleon was forthwith set in motion, and an immediate attack upon each of them resolved upon in order to prevent their union. The first onset of the infuriated Corsican threw back the Prussians at Ligny, June 16. Confident that Blucher's defeated army must retreat in the direction of Namur, and intent upon pursuing his advantage, Napoleon prepared a concentrated attack upon the British and allied troops, whom he found in a strong position near Waterloo, but not apparently strong enough for continued resistance. Never was general more mistaken. The British army never quailed a moment before his terrible attack, nor was the duke disappointed in the firm confidence he reposed on Blucher's promise. Without giving his troops any rest after the sanguinary conflict of Ligny, through soaking roads and through an opposing French corps under Marshal Grouchy, the veteran soldier pursued his onward march, and suddenly appearing in the rear of the French lines, opened a galling fire of artillery just when the decisive moment had arrived. The battle won, Blucher and his hussars knew of no rest in their vehement pursuit, which transformed the retreat of the French army into a mad and hopeless flight. The Duke of Wellington and Marshal Blucher, whom the commemoration medal represents under the figures of Castor and Pollux, entered Paris together. In the ensuing negotiations of peace the Prussian plenipotentiary demanded that the two purely German countries which intrigue and violence had wrested from the empire in the seventeenth and eighteenth centuries should now be re-united with the Germanic Confederation. This attempt at recovering for Germany its really "natural" boundaries (strictly speaking, there are none other but the Vosges and the Ardennes mountains) remained unsuccessful; France was obliged to surrender those only among her acquisitions which she had made since 1790. Soon after the conclusion of peace the labours of the Congress of Vienna were resumed, from which Prussia received that extent of territory which, with some very slight modifications, she now possesses.

The remaining years of Frederick-William III.'s reign were passed in comparative tranquillity. The king was to the end an attentive governor of his country, much respected and beloved, but not independent enough from the influence of Russia and Austria to persevere in the progress of liberal institutions that had effected such a salutary change in 1807 and the following years. His promise of a parliamentary constitution, repeatedly given in the days of adversity, was not fulfilled in those of prosperity. He thought it unsafe to go beyond the re-organization of the provincial parliaments, or *Stände*, which he effected by an edict of the year 1823, re-assembling, with a slight modification, the old Stände over again, as described above,—viz., a representation of the nobles, the burghers, and the peasants, each separately charged to occupy themselves with provincial matters only, and those of the most restricted nature. Although the disaffection caused by this tergiversation never led to serious collisions with his people, yet the educated classes in the country had an ever-growing sense of injustice committed and rights withheld, and conceived a hearty dislike of the close political intimacy between their court and the despotic rulers of Austria and Russia. Throughout his life the king remained a staunch adherent of the principles of the "Holy Alliance," a treaty concluded at Paris in 1815 between the sovereigns of Russia, Austria, and Prussia, which, if divested of its religious wording (honestly meant, we are convinced, at least by Frederick-William) had no other object but to uphold at any cost, and by every means, the "divine right" and the absolute power of princes throughout Europe. These principles gave a peculiar bias to his behaviour in all European congresses, and somewhat alienated him on several important occasions from the policy of Great Britain. He was blind to the Russian encroachments on the rights of unfettered commerce, which had been guaranteed by treaty to the provinces of Prussia conterminous with Russia. Nor did he awake to a sense of his powerful neighbour's treacherous intentions even when it became known that the Emperor Nicholas had secretly promised to the court of Paris in 1829 the acquisition of all Prussian possessions on the left bank of the Rhine. In spite of these shortcomings in the king's internal and foreign policy, Prussia continued progressing during this relaxation from war. The administration of the country, though far too active and meddling, was throughout a conscientious and vigorously honest one. Justice was administered with complete independence from court or any other influence. The duty of parents to give a proper education to their children, and to send them to a public school, if unable to do so at home, was proclaimed as a fundamental principle in 1816. Another duty resulted from this,—viz., that of the parishes to endow schools, and of the state to assist in this endowment where the parishes were incompetent. A series of laws gave effect to the declaration of these duties; and they have undeniably rendered the practice of reading and writing a more general accomplishment than in any other country. Frederick-William's government, although an almost parsimonious one, never stinted public educational institutions. Normal schools or seminaries for training village schoolmasters were founded in every province. During his reign no less than seventy new gymnasia or Latin schools were founded and adequately endowed. The material interests also received every attention at the hands of government. A tariff of *ad valorem* duties on foreign merchandise, based on liberal principles, was published in 1818. It proved very beneficial to the interests of the people as long as it lasted. But its principles were unfortunately exchanged at a later period for more and more protective duties, in proportion as the Zollverein or German customs-unions (founded in the years from 1819 to 1836) extended farther to the south of Germany, and as its protectionist influence gained an ascendancy over the free-trade propensities of the north.

King Frederick-William occupied himself much with a settlement of the Protestant Church, to which his family and majority of his people belonged, and attempted also the still more difficult task of regulating the relations of his state with the Roman Pontiff as head of the Roman Catholics. In both directions he was but partially successful. The division of German Protestants into Lutherans on one side, and Calvinists (or *Reformirte*) on the other, though it had lost many of its asperities, was still an impediment to good feeling, or to the creation of a national church. Frederick-William, after earnest deliberation, pronounced his desire that each of these Protestant communities, whilst retaining its distinctive dogmas, might nevertheless admit the other into Christian fellowship, and, in order to give the example of brotherhood, he partook of the sacrament at a Lutheran Church, although himself a Calvinist (or *Reformirter*), on the 31st of October 1817, the third anniversary of the Reformation. Like him, the Protestants in several cities of Germany united in worship on that day. Henceforward the name "Evangelic Church" was used officially, instead of the distinctive appellations formerly in use. This union of the several Protestant churches was founded by the king in a real spirit of Christian charity, and with distinct provisos that no individual or congregation should in any way be compelled to adhesion. Unfortunately, when many strict Lutheran congregations objected to the union and to the *Agende* (or Book of Common Prayer), published by command of the king in his capacity of *summus episcopus*, acts of force were applied, and the liberty of conscience infringed. For these gross acts of injustice the greater share of blame falls on the persons entrusted with the execution of the royal will; much, however, remains to be attributed to the king's own impatience of opposition or dissent. Far graver complications met his attempts at an adjustment of his relations with Rome. A concordate having been agreed to between Prussia and the Pope in 1821, by which the former acknowledged a regular Roman Catholic hierarchy, consisting of two archbishops and six bishops, and undertook to pay a fixed sum annually towards the endowment of that church, everything seemed to progress smoothly by mutual forbearance. But after a time difficulties arose. In 1837 the Archbishop of Cologne, Baron Droste-Vischering, declared that he would henceforth allow no marriages between Roman Catholics and others to be consecrated by priests of his diocese, except under the distinct promise, that all children should be brought up in the Roman Catholic religion. He was in vain reminded of the promise he had himself given in writing previous to his accession to the archiepiscopal see, faithfully to obey the laws of the country and the arrangements entered into by his predecessor. He obstinately refused compliance. At length the Prussian government, losing all patience, directed his forcible removal from his see as a state-prisoner, on the ground "that he had broken his word, violated the laws of the kingdom, and excited the minds of the people under the influence of two revolutionary factions." This transaction led to endless discussions, which might have been terminated more satisfactorily had the government resolved at once upon placing the archbishop on his trial on the above grounds in a public court of law.

The following is a summary of events since the elevation of Brandenburg-Prussia into a kingdom:—

1701.	The Elector of Brandenburg and Duke of Prussia declared King of Prussia.
1701 to 1713.	Frederick I.
1713 to 1740.	Frederick-William I.
1740 to 1786.	Frederick II., or the Great.
1740 to 1742.	First Silesian War.
1744 to 1745.	Second Silesian War.
1756 to 1763.	The Seven Years' War.
1772.	First partition of Poland.
1785.	The German League of Princes.
1786 to 1797.	Frederick-William II.
1792.	Invasion of France.
1793.	Second partition of Poland.
1795.	Third partition of Poland.
1795.	Peace with the French Republic concluded at Basle.
1797 to 1840.	Frederick-William III.
1801.	Peace of Luneville.
1806.	The German Empire ceases to exist.
1806.	Battle of Jena.
1807.	Peace of Tilsit.
1807 to 1808.	Reforms in Prussia.
1812.	Napoleon's march against Russia; General York concludes an armistice with the Russian general.
1813.	The War of Liberation; battles near the Katzbach, Kulm, Grossbeeren, Dennewitz, Leipsic.
1814.	First peace of Paris.
1815.	Napoleon's return; Battle of Waterloo, or of "Belle-Alliance."
1817.	Union of the Lutheran and Calvinistic Churches in Prussia.
1819 to 1836.	The German Zollverein gradually extends itself.

Frederick William IV.

On the accession of Frederick-William IV. to his father's throne, the long-suppressed desire of the people for a direct parliamentary participation in public matters was loudly and loyally expressed. The hopes throughout the country were great, as the crown-prince had been known to entertain views opposed to the all-powerful influence of Prussia. A brilliant power of speech, mildness of disposition, and the manifold kindness to such as had latterly suffered from persecution or neglect, all combined to produce expectations of reform far beyond what the new sovereign had ever intended. Given to mediæval studies, and at the same time an admirer of English institutions, he was, it is true, averse to the severe regularity of Prussian bureaucracy and red-tapeism, and would have liked to see a brilliant assemblage of peers and knights around his throne, as in olden days; but he proved to be over-sensitive to the slightest infringement of royal prerogative, and abhorred the idea of parliamentary bodies that would have or show a will contrary to his. The consequence was a disappointment and mistrust on the part of the people, and on his a gradual relinquishment of the leniency and liberalism of his first years, a tedious, inactive, and undecided course of

History.

policy. A number of years of peace and tranquillity, of waiting and patient obedience, were allowed to pass away before any reform of the country's institutions was attempted. To the people the uncontrolled and even increased power of red-tape bureaucracy, of what was termed the police-state (*Polizeistaat*), became less endurable as the years advanced. And when at last, in 1847, a royal decree summoned together the members of all provincial parliaments to a combined sitting in Berlin, their power was so limited, and the tenure of this power so precarious, that the assembly, although animated with very loyal sentiments, and containing a totally unexpected amount of talent, effected none but negative results. The fulfilment of a promise of nearly forty years' stand[illegible] was insisted upon; and the grants of money, even for public works of undoubted utility were refused, until a real representation of the people should be established. Nevertheless, a general belief existed, that by this important "first step" of 1847 a series of reforms was inaugurated which must lead, if not rapidly, at least surely and peaceably, to a full victory of parliamentary principles. The loyalty of the people to their Hohenzollern dynasty, and the spread of education throughout all ranks, seemed to preclude the possibility of this progress being interrupted by sanguinary conflicts; also, the finances of the state were in so flourishing a condition, the general administration of the country so free from the taint of corruption, and on the whole so just, that it seemed unnecessary for this state to pass through violent storms of revolution. But it was decreed by Providence that these fair hopes of king and people should be destroyed. The year 1848 shook the foundations of the Prussian state, together with those of the entire continent of Europe. A time of anarchy intervened. And although its upshot was a constitution (of 1850) as liberal in all essentials as any in Europe, it gained so little vitality during the remainder of the king's reign (to 23d of October 1858), that the country seemed on the whole to have moved backward in this respect rather than forward since the assembly of 1847.

As in this particular question such was the king throughout. Amiable, willing to conciliate, and unfortunately possessing a *half-insight* into the requirements of his age, he was apt to give just enough to produce a craving for more, not enough for permanent gratitude and satisfaction. He showed attainments of no ordinary character; and among his personal friends are numbered some of the most enlightened men of his age and country. Yet the liberty of speech, and that of the press, were never more cramped than it was after the halcyon days of his first popularity. The king's orthodoxy in religious matters has proved inoffensive, and always tolerant to the belief of others. Yet his policy in this direction was influenced more and more by men of the narrowest and most exclusive opinions.

The first part of Frederick-William IV.'s reign (1840 to 1848) was one of rapid development in all arts of peace, in manufacture, in trade, commerce, and navigation. A comprehensive system of turnpike-roads (for the most part made and kept up by the state), on which his father had bestowed much attention, was brought to completion. Railway companies and other associations for most branches of industry spread over the whole country, and commenced to change its aspect. Prosperity seemed to keep pace with the labour of man. Yet, nevertheless, the spirit of sullen discontent was brooding over the country when the news arrived in February 1848 of a complete *bouleversement* in the neighbouring state of France. Its effect throughout Germany was, in the first moments, simple and patriotic. Cries of "*A la frontière*" had been frequently heard in the streets of Paris; and the first spontaneous burst of sentiment therefore, created by a vivid recollection of long years of invasion and oppression, was expressed in the cries of "Defence against the common enemy," "Close alliance of all German states," "Recovery of the unity of Germany, lost since 1806." This agitation, though most violent in the smaller states, broke forth actively, and at first beneficially, in Prussia. But soon, and almost together with it, a very different pulsation appeared to pervade the people. In France the masses had obtained their will, and were apparently all-powerful. The same then was attempted by the masses in Germany. Every class of labourers and workmen combined for a settlement of their real or imagined grievances. At that time, had the governments possessed the full confidence of the middle classes, all who had anything to lose would have rallied round the thrones to ward off the common dangers of society; but that confidence was gone. The middle classes demanded reforms, on the whole, it may be said, of a moderate nature. With scarcely any resistance, these were accorded in the smaller states. Men of liberal opinions were called to offices; but the danger proceeding from the lower classes was on the increase. There appeared but one hope of protecting society,—viz., if the King of Prussia would declare his assent to the same reforms, and promise to use his best efforts towards a more efficient defensive union of Germany. Delegates from all the minor governments, including the Bavarian, proceeded to Berlin in the beginning of March to implore the King of Prussia, who had as yet experienced comparatively small pressure at the hands of his subjects. The king's scruples were at last overcome after the arrival of the astounding news of Prince Metternich's fall at Vienna (15th March). A royal proclamation, eloquently expressing all that had been demanded, was prepared, signed, and published, on the morning of the 18th, to the great joy of the Berliners, who assembled before the palace to express their satisfaction. Then suddenly two shots, fired nobody knows by whom, produced a commotion. French and Polish *barricadiers*, who were everywhere in great numbers in those days, raised a hue and cry after arms throughout the city, and in a short time all the elements of confusion of a populous town were in readiness, two hundred thoroughfares stopped by barricades, and the masses in conflict with the king's troops. A street fight ensued. The combat lasted through the night, and ended towards morning, when nearly all the barricades were evacuated by the insurgents. In this juncture of affairs an unexplained, and in fact inexplicable, command to the troops was issued from the palace early in the morning, ordering them to march out of the capital. The effect was such as might have been supposed. The insurgents came forth victorious, parading through the streets the bodies of those who had fallen; galling insults were heaped upon the king and queen; complete anarchy was triumphant. All hopes of protection from this quarter were now abandoned. Revolution had full sway, and ran its course during a time; not a bloody one on the whole, yet so subversive, that the higher and a great part of the middle classes abstained from its doings altogether. Its effects have not been salutary. It brought to light a hidden animosity of all classes against each other. In Prussia, as in most other German states, it led in the end to restrictive measures, which, in their turn, overshot the mark, and have rendered the easy comfortable rule of past years almost an object of regret to the people at large.

King Frederick-William IV. had called the leaders of the former liberal party to his councils. They willingly came and did their best. The old parliament was for the last time convoked in April, to give its sanction to general elections for a new one, which was to frame a constitution in conjunction with the king's government. The result of the ultra-democratic elections was discreditable to so educated a country as Prussia. After committing every kind of extravagance, and baffling the attempts of divers sets of ministers, this so-called constituent assembly was dissolved in October 1848 by a new cabinet, which, had the worthy general Brandenburg (an illegitimate son of King Frederick-William II.), and a man of not so stainless a reputation, Baron Manteuffel, among its leading members. The king, in dissolving the assembly, published a constitution of the monarchy, and issued writs for the election of another parliament, with a view to its revision and final settlement. Everything had changed meanwhile. A directly opposite class of members now filled the benches,—*i.e.*, noblemen and *employés*,—quite as eager to protect their interests, and, if possible, to restore the old condition of things, as the former members had been to diminish their power in the state. Thus Prussia was thrown from the hands of silly democrats into those of an aristocratic clique and of partizans of the divine right of kings, so well known in the history of our own Restoration. Under the general dread of revolution and anarchy which pervaded the possessing classes, and with a king more and more averse to liberal measures, this party of nobles and zealots became the most powerful in the country, and has remained so during the succeeding years.

We had occasion to mention the defensive and unitary movement throughout Germany on the first outbreak of the third French revolution in 1848. Under the influence of an unruly democracy, this movement, when all danger of French invasion had passed over, took the shape of a fixed plan for proclaiming a German republic, after an overthrow of in all thirty-three German sovereign thrones. The opposite extreme to this was a desire (entertained by very few at that time) that matters should remain as they had been since 1815, viz., thirty-three monarchies and four free cities, independent in their action, and bound together by a federal tie—a constitution which had shown, as must be confessed, little or no vitality except for the suppression of liberty in the different states. A third party, which gradually numbered among its members nearly all men of moderate views, and some even among the German sovereigns, proposed to re-establish the German empire without removing the landmarks of any of the single states; leaving every sovereign and every city intact in all except the common affairs of Germany, namely, war, diplomacy, customs. These common affairs were to be directed by the new emperor with an imperial ministry responsible to a national parliament. The main difficulty of this patriotic scheme, that in fact which would alone have necessitated its failure, was the existence of two such states as Austria and Prussia within the German Confederation. Of Austria it was said that her interests were entirely of a European, not of a German character. The kingdom of Prussia, on the contrary, had no non-German population (with the exception of about a million Poles) or interests, and accordingly that party looked to Prussia as containing the most appropriate dynasty for the future German empire. The leaders of the German constituent assembly, which proceeded from general elections, and met at Frankfurt-am-Main on the 15th of May 1848, were mostly of this opinion, and so were the leading men in most governments of Germany at the time, including also (although, strange to say, not prominently) the Prussian cabinet. By the time they had finished their long-winded debates on secondary matters, most sovereigns in Germany had sufficiently recovered from their terror to dismiss their councillors, and to oppose the inconvenient scheme of unity. At length, on the 28th of March 1849, the party thought their labours crowned, by carrying the election of the King of Prussia to the headship of the new German empire. The king's answer to the deputation sent to offer him this new dignity was to the effect, "That he could not accept it without the free consent of all German sovereigns; that it lay with these sovereigns to consider whether the proposed constitution was conclusive to the welfare of each individually, and of all collectively, and whether it would enable him to direct the destinies of Germany with a firm hand." In the evening Schiller's play of "The Robbers" was acted in the royal theatre, to which the members of the deputation were *ex officio* invited. Little edified either with his majesty's refusal or with those theatrical insinuations, the deputation returned to Frankfurt. On their report, resolutions of "standing by" the new constitution were passed in the assembly. But the fatal motto of those days, the "trop tard!" again showed its truth. The Prussian members, as well as the Austrians, were revoked by royal command, and the remainder, a kind of "rump parliament," having withdrawn to Stuttgardt, were soon finally dispersed. Instead of simply leaving the matter alone, King Frederick-William IV. committed the incredible folly of attempting a more united organization of part at least of Germany, "with the free consent of its sovereigns!" The failure of these attempts, at a time when princely prerogative was again in the ascendant, and all feeling of immediate danger had passed away, was inevitable. Backed by the middle states of Germany (Bavaria, Hanover, Würtemberg, and Saxony), Austria advanced to oppose these Prussian half-measures, which were but despondingly supported by the nation at large, and a complete humiliation of Prussia was the result. All further attempts have ceased since the convention of Olmütz, 29th of November 1850. The confederation is again just what it was; its old assembly of delegates (Bundestag), convoked again in its former composition by Austria in 1850, was acknowledged by Prussia in 1851. Its influence has again shown itself only in recommending the suppression of liberal constitutions in Germany. Still it deserves attention, as the only acknowledged bond of union among the totality of German states.

The Prussian constitution fared somewhat better. Its paragraphs were carefully revised, and the king took the prescribed oath on the 6th of February 1850. Numerous modifications in it have taken place since, under the influence of violent "legitimist" majorities. It would be vain also to say that the king and his government were rendered less absolute by its provisions than they had been before,—such was the apathy of the country following the revolution of 1848. Yet it is an advantage to Europe that we can still name Prussia among the constitutional countries where no money can be spent, no law promulgated, without the assent of a representation of the people; in which every grievance must find a hearing, even if it does not always find redress. This is perhaps the chief gain to Prussia of the turbulent years of 1848 and 1849. Another gain, and not of smaller benefit perhaps, is the abhorrence now existing among Prussians, and in fact throughout Germany, against political and social theories, ever since their entire failure in 1848. Yet another advance, which it would be difficult to explain, is the greater activity imparted to all industrial and commercial undertakings within the years 1850 to 1858, which (to give only one example) has more than doubled the production of native Prussian iron within five years. It would seem as if the country had tried to forget, in this busy trading and commercial activity, the intense chagrin which maladministration was everywhere engendering. All the faults of the *régime* previous to 1848 were now exaggerated tenfold. The court-party ruled the king and his ministers, and crept into all places of importance in the state; hypocrisy in religious and political matters was rewarded by distinctions and employment; religious dissent was repressed and punished by disabilities; even bribery and corruption, from which Prussia had been pre-eminently free, began to assume the functions of a regular principle of government; the police exerted a kind of discretionary power; the servants of government in the provinces seemed to imitate the example of French *préfets;* the elections were ruled by intimidation, and brought into the Chamber of Representatives an incredible number of men in the pay of, and dependent upon, government.

In foreign politics the king's disposition was directed through life to the maintenance of peace. He visited England at the invitation of Queen Victoria to stand sponsor to the Prince of Wales in 1842, and ever professed a great admiration for British institutions. He made an exception to his peaceful policy, in 1848, when he attacked a Danish army by order of the German Confederation, to protect the duchy of Holstein, which is one of the states of that confederation. On account of these proceedings, the king has been suspected of ambitious motives, and of a desire to annex that duchy, and its closely-united neighbour Schleswig, to his own dominions. Of this he was innocent. The truth seems to be, that a deep-rooted animosity of the German population, both in Holstein and Schleswig, led them to an untimely attempt at separation from the Danish monarchy, instead of waiting for an opportunity which time must have brought, viz., the extinction of the male line of rulers in Denmark, and, contingent upon this, the accession (by the Salic law) of a separate dynasty in the duchies. The war has embittered the sentiments on both sides to an irremediable extent, without any redress of grievances, and has brought upon Prussia and the Germanic Confederation the profound humiliation of having created hopes, sent armies and generals (in 1848 and 1849), and then (1850) pusillanimously abandoned those whom they had declared to be in the right and had undertaken to protect. Another short but bloody war was forced upon King Frederick-William by an insurrection among his Polish subjects, the explosion of which had been adroitly prevented by the government in 1847, but which broke out and assumed rather formidable dimensions in the disastrous spring of 1848. It was suppressed, but not before a series of sanguinary combats had proved to the Polish insurgents how unavailing scythes are against rifle-balls and shrapnells. A considerable Prussian army marched into South Germany in the summer of 1849, at the request of the Grand Duke of Baden, whom a wide-spread mutiny among his own troops had forced to abandon his country to a clique of republicans and their besotted followers. Baden and the Rhenish possessions of Bavaria (also in the power of insurgents) were occupied after a short resistance; and similar outbreaks in Würtemberg and Bavaria proper prevented by this timely aid. In the oriental war (1853 to 1855) Prussia abstained from military co-operation; and was admitted to the Congress of Paris only when its work was finished and all but ready for signature. The territory of Prussia underwent no important changes during this king's reign, excepting that the provinces of Prussia proper and Posen (the latter so far as its population is German) were formally introduced into the Germanic Confederation in 1846, and as formally replaced on their old footing in 1850, it being gravely asserted by the politicians of the day, that the position of Prussia as a European power depends in a degree upon her possessing lands without as well as within the said confederation! Another change, implying a trifling loss, must be transitorily mentioned, viz., the resolution of the little canton of Neufchâtel in 1848 to belong henceforward to Switzerland alone, independent of the King of Prussia, who had inherited it, and very mildly exercised his sovereignty. The king set a great value on the recognition of his right, and all European powers gladly recognised them; but when he threatened actual warfare, to back the attempts of the royalist party in the canton (A.D. 1856), the same powers interposed, and the canton was amicably left to itself and to Switzerland early in 1857.

In the autumn of the same year the king was visited by several strokes of apoplexy, which impaired his power of speech, and in part also his reasoning capacities. The sympathy with this melancholy downfall of a highly-gifted and amiable sovereign was general among all classes of the people. But their indignation was soon kindled by the artful intrigues of the court party, who caused the unfortunate monarch nominally to retain the government, merely desiring his eldest brother William (who had borne the title of "Prince of Prussia" ever since the late king's death, as heir-apparent to the throne) to conduct the affairs of state "in accordance with his (the king's) known intentions." The meaning of this was absolute power concentrated in the hands of the then cabinet, under the presidency of Baron Manteuffel, whom to dismiss would have been, on the prince's part, to overstep his instructions. Fortunately for Prussia, no European event of grave import occurred in this first year of the king's malady; and the country, although without a ruler, and oppressed by the host of ministerial police, passed through this agonizing twelvemonth, outwardly at least, unharmed. On the expiration of that term in October 1858, the king, in accordance with a paragraph of the constitution which makes provisions in case of a king being "lastingly incapacitated," signed an order conveying to his brother the full and unrestricted powers of regency, and left Potsdam soon after to pass the winter in a southern climate. Since then public matters in Prussia seem to take a more favourable turn. A new cabinet, containing the leaders of the opposition, is ably supported by the majority of a newly-elected Chamber of Representatives. Divers practices of the former administration have been simply dropped, and bills introduced to prevent their recurrence. Reforms are firmly demanded, and will be honestly granted. The prince shows no precipitation in his actions, but gains confidence rather by well maturing his plans. Many are they who would fain hope that Regent William will prove a worthy follower in the footsteps of his namesake, our William of Orange; and that the children of the Princess-Royal of Great Britian may reign over a country blessed with the same institutions as our own, and governed by that obedience to the laws which has rendered our island prosperous and mighty beyond all nations of the earth.

Position. The Prussian monarchy is composed of three territories, very different from each other in size. The first or eastern portion extends from nearly the centre of Germany to the frontiers of Russia and the Baltic. The second or western portion, smaller in extent, and divided from the former by a stripe of land between 30 and 40 miles in width, begins on the frontier of Holland, Belgium, and France, and reaches the course of the River Weser. The third portion consists of the small principalities of Hohenzollern on the Danube, which have belonged to the royal line of that family only since 1850, inclosed within the states of Baden and Würtemberg. The two first and principal portions are situated between 55. 52. and 49. 7. N. Lat., and 6. and 22. 50. E. Long. Its greatest extent is from the French to the Russian frontier, a line, though not quite unbroken, of nearly 800 miles. **Frontiers.** The principal frontier is the Baltic Sea, washing the shores of Pomerania and of Prussia proper, about 520 miles in extent. A waste stripe of coast (the Jahde-port) having being purchased from Oldenburg in 1855 for the construction of a naval port, the Prussian state now has access also to the German Ocean. The land frontiers are,—1*st*, Of the eastern portion, Russia and Poland, on the east; Austria, Saxony, and Thuringia, on the south; Hanover, Hesse-Cassel, Brunswick, Mecklenburg, on the west. 2*d*, Of the western portion, Holland and Hanover, on the north; Lippi, Brunswick, Hanover, Hesse-Cassel, Waldeck, Hesse-Darmstadt, Nassau, and Rhenish Bavaria, on the east; France on the south; Luxemburg, Belgium, and Holland, on the west.

Size. In point of size, Prussia, as at present constituted, nearly equals the area of Great Britain and Ireland. The King of Prussia's territory comprises 111,154 square miles, compared to the 121,050 square miles of the United Kingdom.

Statistics. (For the size of each of the above-mentioned provinces, see Table III.)

Outward configuration. The western portion, including Hohenzollern, is mountainous; the other (with two exceptions, viz., Upper Silesia, and the country bordering on Thuringia) belongs to that interminable plain which characterizes Eastern and North-Eastern Europe. In Brandenburg, Pomerania, and Prussia proper, the plain goes down lower and lower as it approaches the Baltic, against whose ravages it is in many parts protected only by natural or artificial sand-banks. Over this monotonous plain a few small lines of hills are seen stretching along. The land, in part sandy, in part extremely fertile, is intersected by some powerful rivers, large lakes, morasses, and forests of pine and fir. The highest point of this country is the island of Rügen, famous for its white chalk cliffs, which remind the traveller of Dover. Upper Silesia contains a mountainous district separating that province from Bohemia. It bears the names of Waldenburger-Gebirge, Glatzer-Gebirge, and, raised above the rest, the Riesen-Gebirge: the Schneekoppe, its highest point, measures 4931 feet, which is more than the height of any non-Alpine mountain in Germany. Parts of the Thuringian hills are Prussian ground, and likewise a part of the Harz Mountain, with its ghost-haunted Blocksberg or Brocken. The western portion also begins with flat country in the north; soon, however, the Weser hills rise above the plain, followed to the westward by the Teutoburgwald, and farther on by the Westerwald, which ends where it touches the Rhine in the picturesque Sieben-Gebirge, 1429 feet high, and its marked promontory the Drachenfels. The hilly countries to the left of the Rhine are divided into groups by its tributaries,—viz., the Hohe Venn (a part of the Ardennes), between Maass and Mosel; then the volcanic Eifel, north of the Mosel; and the Hundsrücken, south of it. The Hohenzollern country forms part of the Swabian Alps, and is crowned by the ancestral castle of the family on the summit of the Zollern hill (2663 feet high).

The sea. The Baltic Sea is too shallow to offer any first-rate ports; there are, however, good roadsteads along its shores. Its commerce is carried on mainly by the following Prussian towns,—viz., Memel, Königsberg, Pillau, Elbing, Dantzic, with Weichselmünde, Swinemünde, Stettin, and Stralsund, some of which are obliged to send their merchandise along the shallow waters of a haff. These haffs (the Kurische, Frische, and Stettiner) are broad lakes or river-outlets formed by the streams on their sluggish exit into the sea, and so close to the shore that there remains only a narrow stripe or *Nehrung*, through which the river then finds its way out. The water of the Baltic contains five times less salt than the Atlantic. It is ice-bound during three or four, and sometime five, months of the year.

Lakes and rivers. The number and extent of lakes is considerable: there are 389, of more than 200 acres each, which occupy in all an area of 775 square miles. The hand of man has reclaimed by drainage, and turned into splendidly fertile land, immense tracts of bog and morass. These bogs derive their names from the rivers whose course they accompany: thus the Oder-Bruch, most effectually drained by Frederick the Great; the Warthe Bruch, now almost entirely a fertile district 60 miles in length by 10 in width; some 60 square miles of the Obra-Bruch, in the province of Posen, are at present under operation. All great Prussian rivers flow into the Baltic or into the German Ocean, excepting the Danube, which in its upper course traverses Hohenzollern. Beginning from the last, the principal rivers of Prussia are the following,—1. The Niemen or Memel, which enters the Baltic near the town of Memel, after traversing the Kurische Haff, the northernmost of those mighty river-outlets mentioned above. On its banks lies the famous town of Tilsit. 2. The Pregel, which passes into the Frische Haff 5 miles below Königsberg, and into the sea near Pillau. 3. The Weichsel or Vistula, 13 feet deep in the Baltic port of Weichselmunde, near Dantzic, but mostly shallow higher up; its width is 2850 on its entrance into Prussian territory, and increases to 5000 feet. Two other branches of the river (one of them called the Nogat) flows into the Frische Haff; its course is defended by the fortresses of Thorn, Kulm, Graudenz, and Dantzic. 4. The Oder, a mighty stream of 625⅓ miles in length, 583⅓ of which belong to Prussia, collects its waters from no less than 52,267 square miles of land. Silesia, Brandenburg, and Pomerania are traversed by the Oder; among the towns on its banks may be mentioned Oppeln, Breslau, Frankfurt, and Stettin. Its principal tributary is the Warthe, coming from the eastward, 600 feet wide near the fortress of Cüstrin, where it joins its waters with those of the Oder. Another tributary has become famous in history, viz., the Katzbach, which flows from the westward. 5. The Elbe, an important landmark, inasmuch as it separated, and to a certain extent even now separates, the purely Germanic population on its left from a country gradually re-conquered, colonized, and Germanized, after a great immigration of Slavonic races. Having crossed Bohemia and Saxony, it enters Prussia as a navigable river 6 to 10 feet deep, passes the fortified cities of Torgau and Wittenberg, and then flows into Mecklenburg territory. The waters of the Saale, from the left, and of the Havel, combined with the Spree, from the right, swell the stream of the Elbe, which measures 1000 feet after the junction with the Havel. 6. The Weser, a small part of whose course, that which passes the town of Minden, belongs to Prussia, 3 to 6 feet deep, and 140 to 200 feet wide. 7. The Ems must, like the former, be called a Hanoverian river; it has, however, a course of 112 miles in Prussian Westphalia. 8. The Rhine washes Prussian soil from Bingen to the frontier of Holland, a distance by water of 233 miles, or nearly one-third of its entire length, which is 816 miles. Its fall within these limits is no less than 226 feet. Near Bingen it has a width of 1608 feet, which is diminished to 840 feet near Unkel, and then widens out again gradually to 2544 feet near the Dutch frontier. Its principal tributaries are,—from the west, the Nahe, which passes by Kreuznach; the Mosel, with its many cities; and the highly romantic Ahr: and from the east, the Lahn, the Wupper, the Ruhr, and the Lippe,—all four now rising into great importance by the mining and manufacturing activity of its valleys.

Canals. It was a matter of just pride among the Prussians in former times that they possessed a large net-work of canals, connecting their principal rivers and lakes between the Elbe and the Niemen. They are, however, now losing much of their value by the competition of railways.

Climate. The climate of Prussia is on the whole temperate and healthy. In Königsberg the mean temperature shows 43°·52; in Berlin, 40°·2; in Aachen, 48°·875; in Bonn and Treves, 50°. The thermometer does not anywhere rise above 100°, or fall lower than 25° below zero. In the provinces of Prussia proper and Pomerania the winter lasts seven months; there the middle of May is usually considered the beginning of spring; whilst the sun of the Rhine ripens the grape, the almond, and the chestnut. The eastern portion, on the other hand, has more constancy of weather both in summer and in winter. The fall of rain in some of the principal localities of the monarchy, beginning from the east, is as follows:—

	Inches.		Inches.
Tilsit	19·743	Berlin	20·795
Dantzic	18·140	Halle	18·094
Posen	18·863	Münster	25·226
Breslau	15·818	Cleves	27·018
Frankfurt-on-the-Oder	20·055	Cologne	24·190
Stettin	18·376	Treves	25·702

The average annual fall of rain throughout being 21·002 inches.

Statistics.

Population

I. *Population of Prussia at the close of each Reign, since the beginning of the eighteenth century.*

Sovereigns.	Population.	Square Miles.	Average per Sq. Mile.
Frederick I. (1713)	1,731,000	45,080	38·4
Frederick-William I. (1740)...	2,486,000	47,911	51·8
Frederick the Great (1786)....	5,430,000	77,224	70·3
Frederick-William II. (1797)..	8,700,000	121,128	71·8
Frederick-William III. (1840)	14,928,501	110,980	134·5
In the year 1855	17,202,831	111,154	154·8

II. *Increase of Population since* 1816.

Year.	Total Population.	Increase during Three Years.	Average Increase in each of these Three Years.	Yearly Increase in per cent. of the Population.
1816	10,349,031	...	...	...
1819	10,981,934	632,903	210,967$\frac{2}{3}$	1·93
1822	11,664,133	682,199	227,399$\frac{2}{3}$	1·95
1825	12,256,725	592,592	197,530$\frac{2}{3}$	1·60
1828	12,726,110	469,385	156,461$\frac{2}{3}$	1·23
1831	13,038,960	312,850[1]	104,283$\frac{1}{3}$	0·80
1834	13,509,927	470,967	156,989	1·16
1837	14,098,125	588,198	196,066	1·39
1840	14,928,501	830,376	276,792	1·85
1843	15,471,084	542,583	180,861	1·17
1846	16,112,938	641,854	213,951$\frac{1}{3}$	1·33
1849	16,397,448	284,510[2]	94,836$\frac{2}{3}$	0·56
1852	16,935,420	537,972	179,324	1·05
1855	17,202,831	267,411	89,137	0·53

The increase from 1853–55 is thus accounted for:—

		For the 3 Years.	Annual Average.
Excess of births over deaths......... (In Berlin this excess amounts annually to 3053$\frac{2}{3}$.)		353,195	117,731$\frac{2}{3}$
Immigration		8,650	2,883$\frac{1}{3}$
		361,845	120,615
Registered emigration	65,735		
Non-registered emigration.	28,699		
		94,434	31,478
		267,411	89,137

Statistics.

In 1855 the population of Berlin amounted to 447,483; of Breslau, 121,345; of Cologne, 106,852; of Königsberg, 83,593; of Magdeburg, 77,997; of Dantzic, 71,995; of Aachen (Aix-la-Chapelle), 54,373; of Stettin, 52,252; of Potsdam, 32,725 inhabitants.

The density of population varies much according to soil, climate, and occupations. On the whole, however, as will be seen by the following table, the western portion shows a decided preponderance, relatively to its size, in point of numbers. We give these calculations according to departments (*Regierungsbezirke*) rather than provinces, because the former represent, to a certain degree at least, a community of interests and occupation:—

IV. *Relative Population of Departments.*

Name of Department (*Regierungsbezirk.*)	Forming part of the Province of	Number of Inhabitants on every Sq. Mile.	Increase on every Sq. Mile from 1852–55.
Dusseldorf	Rhineland, W.	470	23

Besides Germans, there are in the Prussian dominions at present 2,230,000 inhabitants of divers Slavonic races, Poles, Wends, &c.; also 150,000 Lithuanians, 20,000 French colonists (12,000 of these in Berlin), 10,000 Walloons, and nearly 235,000 Jews. In Silesia, the German population is four-fifths of the whole; in Prussia proper, two-thirds; and in the province of Posen it is a constantly increasing moiety, as more and more land is sold to Germans, and the trade and commerce of cities becomes almost exclusively German. The Polish population amounts to 840,000.

There are 2,809,220 women living in wedlock in Prussia. The average number of children to each family is 3,—a good deal more than France, which has an average of 2$\frac{1}{3}$. In 1855, 131,911 couples were married, 83,053 of which belonged to Protestant churches, and 46,997 to the Roman Church. The number of births in the same year was

---

[1] In 1831, the cholera year, the actual increase was only about 28,000.

[2] Years of revolution.

[3] No official accounts having yet been published of the last triennial census, which was taken in the autumn of 1858, we are obliged to give the numbers of 1855.

Statistics.

617,817—*i.e.*, 317,823 boys, and 299,994 girls; or 17,829 more of the former. This preponderance of males goes on increasing up to the seventeenth year, when it diminishes so much as to leave the male population of the whole monarchy in a minority altogether of 47,695.

The proportion of illegitimate children to those born in wedlock has not varied very much since the year 1816, when we have the first perfectly reliable information. For every 100 legitimate children born in that year there were 8 illegitimate ones; in 1828, only $6\frac{9}{10}$ths to every 100 legitimate children; and in 1852, a little above 8. Illegitimate births vary therefore between 1 to 15 and 1 to 12 in proportion to legitimate ones.

Of the 550,460 persons who died in 1855, there was 1 case of death to every 32 Protestant inhabitants; 1 to every 29 Roman Catholics, and only 1 to every 51 Jews. The rate of mortality averages about 1 to 31 living inhabitants. Still-born children average at 5 per cent. of all deaths, and at $3\frac{3}{4}$ths per cent. of all births. One-fourth of all deaths in a year are of children under one year of age. The number of suicides has increased in a frightful proportion in the period from 1816 to 1855. In the former year there were registered 700, or about 1 to 15,000; and in the latter, 2351 suicides, or about 1 to every 7000 inhabitants.

Classes, or *Stände.*

We find three classes usually distinguished in the population of Prussia, as in that of all continental countries; albeit their distinctions seem greatly to evanesce, viz.:—1*st*, Nobles; 2*d*, Burghers; 3*d*, Peasants. The title of nobility is inherited in Prussia, as it is throughout the Continent, by all members of the family alike; the property, however, if any there be, customarily goes to the eldest son. The law acknowledges as belonging to the high nobility (*hohe Adel*) the heads of those princely houses which enjoyed a kind of sovereignty during the German empire, sixteen in number. These are considered as of equal rank for purposes of intermarriage, &c., with the sovereign houses; they are exempt from military service in Prussia, and enjoy other privileges. Several other great families of Fursten (princes) and counts are by courtesy reckoned among the high nobility, and some fifty families, which take precedence over others in virtue of certain hereditary dignities. All other counts, barons, and simple nobles (*Herrn von*) belong to what is called the lower nobility. The number of these families in the monarchy is 20,000. The nobility is most numerous among the Poles, where 1 out of every 100 is reckoned a noble; it is *least* numerous in the Rhenish province. Many noble families possess very large estates; yet the property, where not fettered by *majorats* (similar to those in Scotland), has changed hands a good deal. Thus we find that in 1855, out of 11,714 ancient *Rittergüter*, or seigneurial estates, entitling their owners to a representation in the old provincial parliaments throughout Prussia, only 7025 still remained in the hands of noble families.

The second class of towns-people, or *Bürger-Stand*, is by far the most intellectual, as well as the most wealthy, in the country. To the higher Burger-Stand belong the *employés* (*i.e.*, those among them who are not born "noble"), the clergy, judges, teachers, all *studierte Leute* (*i.e.*, who have enjoyed university education), artists, merchants, manufacturers, &c. The lower Burger-Stand comprises trades-people, artizans, and towns-people owning land. The third class, or *Bauern-Stand*, are inhabitants of the villages and hamlets (32,000 in number), and of separate farmsteads not belonging to any village (also nearly 30,000). This class numbers more than twelve millions (71·2 per cent. of the population), living in nearly 1,400,000 dwelling-houses. Many of these are proprietors of land, and all equally attached to their property, from the substantial Westphalian *Bauer* of 400 or 500 acres, down to the Rhenish labourer, who cultivates in leisure hours his own acre of land.

Statistics.

Religious denominations.

The majority of Prussians, viz., 10,534,754, belong to one or other of the Protestant churches; the rest are for the most part Roman Catholics (6,418,310 in number, or about $\frac{3}{8}$ths of the entire population), some Mennonites, a few of the Greek Church, and, finally, 234,248 Jews. Protestantism is greatly dominant in the provinces of Pomerania, Brandenburg, Saxony, and the eastern part of Prussia proper, and is in a majority in the Silesian departments of Liegnitz and Breslau, in the Westphalian departments of Minden and Arnsberg, and in the western part of Prussia proper. The Roman Catholics prevail in Hohenzollern, in Rhineland and Posen, in Upper Silesia, and in the department of Münster. Under the head of Protestants are comprised—1*st*, The members of the United or Evangelical Church, which may be considered as the national church; 2*d*, The so-called Old Lutherans, who have their separate establishment; and 3*d*, The Moravian Brethren. The Mennonites derive their name from a certain Menno, a mild Anabaptist reformer, whose efforts, from 1536, when he left the Church of Rome, to his death in 1561, had been to unite all those who were in favour of adult baptism into one church of saints, living at peace with all men. His followers, like the Society of Friends, reject the use of arms and decline taking oaths; and the state grants them dispensation from both, a certain income-tax of about 3 per cent. being fixed in lieu of their military duties, and their solemn affirmation being accepted in courts of law wherever an oath is required from others. The Jews are most numerous in the province of Posen, where every eighteenth inhabitant belongs to that religion. In Berlin they are as 1 to 38, in Rhineland as 1 to 95, and in the province of Saxony as 1 to 355. The last remnant of their civil disabilities has legally ceased altogether since the promulgation of the constitution of 1850; nevertheless they remained practically excluded from several employments, such as the office of judges; but henceforward the law is to be carried out to its letter, which undoubtedly excludes them from no dignity in the state whatsoever.

The number of churches and other places consecrated for divine worship was, in 1855, 9203 belonging to Protestants, and 7622 to Roman Catholics; which is an unfavourable proportion on the Protestant side; for, whilst their numbers in the country are, roughly speaking, as 5 to 3 compared to those of the Romanist persuasion, their places of worship are not quite as 4 to 3. A similar disproportion exists as regards the ministers of each church, the Protestants numbering 6199, and the Roman Catholics 5796. There are 30 Mennonite meeting-houses, 3 Greek churches, and 928 Jewish synagogues.

The outward government of the Protestant United Church belongs, as in England, to the king, as *Summus Episcopus*. His attributes of power are now entrusted to a supreme council (*Ober-Kirchenrath*), consisting of clerical and lay members, appointed by him, and responsible only to himself. Those points alone in which a contact is established between the state and the church fall under the cognisance of one of the king's responsible ministers,—of public instruction, &c. Each province has a board similarly constituted, called *Consistorium*,—the special control over the clergy, and their doctrine, being entrusted to superintendents-general, one for each province, and superintendents, of which every province has several. The nomination to a cure of souls (subject always to the candidates having duly qualified themselves by examination) belongs in some places to the king, in others to country gentlemen, in others to the municipal authorities, in others, again, to the free election of each congregation. This last-named method forms the rule among the Protestants of Rhineland and Westphalia, who have a presbyterian constitution similar to that of the Established Church of Scotland. They have synods and general synods, in which clergy and laity are equally represented, and manage their local government also in a peaceable alliance of the lay with the clerical element. It is believed that similar representative institutions and local self-government will in time become general in Prussia and in the rest of Protestant Germany.

The Roman Church has eight episcopal sees in Prussia, which do not correspond to the eight provinces of the state. Two of these sees—viz., that of Cologne and that of Gnesen and Posen—are governed by archbishops; the see of Breslau by a "prince-bishop;" the "exempt" see of Ermland, extending over the east of Prussia proper, by a bishop; and so likewise the rest of the sees,—viz., Culm (containing parts of Prussia proper and Pomerania), Münster, Paderborn, and Treves, by bishops. The Archbishop of Cologne exercises jurisdiction over the sees of Treves, Münster, and Paderborn, as well as his own immediate diocese; and likewise the Archbishop of Gnesen and Posen over that of Culm. In the sees immediately committed to their care the archbishops are assisted by *Weih-Bishöfe.* The prince-bishop of Breslau and the bishop of Ermland, whose sees are therefore called "exempt," receive their orders direct from Rome.

Agriculture.

Prussia is essentially an agricultural country. More than two-thirds of her population are devoted exclusively or principally to the cultivation of the soil. Whilst the manufacturing industry, on a larger scale at least, is of modern growth in this country; several districts have ever been exporters of grain, rape-seed, flax, &c. Still Prussia has not attained to that degree of excellence for which she seems to be peculiarly fitted, by the fair conditions of climate and of soil, and by the general intelligence of her inhabitants. In nearly all districts of Prussia the production of grains is so much the one object of agriculture that the art of breeding and fattening cattle suffers from neglect. Meat being sold by weight mainly, and not sorted according to quality, fat cattle are not profitable property. Instead of large outlay and large crops on a small surface, we meet on the whole with oversized farms, costing little and producing little. There is an expenditure generally on extensive and massive buildings out of all proportion to the cost of everything else, and to the disposable capital.[1] The nobles, although they possess very large estates, and although many of these are under their own management, contribute but little to the progress of agriculture. After all the shackles of vassalage and serfdom have been removed, there were, until lately, two principal causes retarding agricultural progress: first, the scarcity of good roads and other means of communication; and, secondly, the scarcity of ready capital. Both causes of inferiority to other countries are now disappearing, and Prussian agriculture will, it may be anticipated, speedily rise to the first place on the continent of Europe. The improvements of Scotch and English agriculture have been carefully watched, and to a considerable degree introduced. Farms of moderate size, with appropriate rotations of crops, with good buildings and implements, using guano and other purchaseable fertilizers largely, are becoming more and more general. Breweries, sugar-factories, and distilleries are to be found on many of these farms, raising the value of the raw produce of the land, and delivering over immense quantities of food for the fattening-stall and the cow-house. Out of the number of about seventeen millions of acres which represented the uncultivated area of the monarchy in 1849, nearly three millions were reclaimed by the end of 1852; and these three millions of acres have become principally grazing land. The fertile province of Saxony stands highest in agricultural improvement generally. It is followed by Brandenburg, which is almost the poorest by nature. The rest can be ranked as follows:—Rhineland, Silesia, Westphalia, Pomerania, Prussia proper, and Posen.

Brandenburg and Silesia are the principal sheep-breeding provinces. Every possible care and refinement are brought to bear on the production of wool, which is the finest in the world, but scarcely any on that of mutton, which is very bad.

Farms.

Large farms are the rule in Prussia. With the exception of the Rhine-valley and the Eichsfeld (on the borders of Franconia), where land is subdivided to a very minute degree, farms varying from 400 to 1200 acres form the majority. They are usually let to tenants. The cultivation of estates in the hands of the proprietor himself, however, is by no means rare, and becomes almost the rule in some districts, in the same measure as the taste for agricultural pursuits increases among the higher classes of society. The provinces of Rhineland and Posen contain the largest number of let farms; there are few such in Saxony, and scarcely any in Pomerania. As regards the duration of leases, they are restricted to nine, six, or even three years, on the Rhine and in Posen; show an increase in Westphalia, where nine to twelve years form the rule; and are longest in the eastern provinces (Posen excepted), viz., twelve to twenty-four years. The rental averages L.1, 7s. per acre in the fertile and much-subdivided valley of the Rhine; and in the sugar districts of the Saxon province, where even L.4, 10s. and L.5 rent per acre is not unfrequently paid. On the dreary hills of the Eifel and of the Westerwald (Rhineland) you meet with farms that are let at 5s. to 7s. an acre. The average rental in the eastern portion of the monarchy (excepting Saxony) may be estimated at from 9s. to 18s. for large farms, and from 12s. to 24s. for smaller holdings. In speaking of the price of land, we necessarily include meadows and woods, with the arable portions. From L.7 to L.12 per acre may be taken as a fair average price of land in Prussia. In the Saxon province, however, the average cannot be rated lower than from L.12 to L.18. The greatest extremes in the value of land may be observed in Rhineland; here estates are sold for L.1 to L.5 an acre along the hills of the Westerwald, Eifel, and Hundsrück, whilst in the valley of that noble river the price varies from L.18 to L.35 an acre for large farms, and from L.40 to L.100 for single fields.

Leases.

Rental.

Price of land.

Prussia proper.

The extensive meadows in the districts of Gumbinnen and Königsberg offer an excellent opportunity for the breeding of horses. Accordingly, most proprietors keep private studs. The principal stud of the monarchy is Trakehnen, in this province, formerly belonging to the royal family, and now to the state, with 1300 brood-mares, and a farm of 9363 acres adjoining. From this immense establishment the royal stables are provided with carriage and saddle horses, and the rest sold in great annual auctions to buyers from all parts of the world. There are two other great studs in the kingdom, viz., Neustadt in Brandenburg, and Graditz in Saxony. Eight less extensive studs, with 1050 stallions, are distributed over the country. Wheat, peas, and potatoes form the principal produce of this province. In the district of Ermland there is also a considerable cultivation of flax. Emancipation from bare fallow, and from the miserable implements of the country, is traceable everywhere. But owing to its commercial disadvantages, viz., its inconvenient and ice-bound harbours, and the exorbitantly high protective duties imposed by Russia; owing also to the sluggishness of its Slavonic and Lithuanian inhabitants, that progress is but slow.

---

[1] The proportion of cost of farm-buildings to the whole capital invested in an estate is calculated at 15 to 20 per cent. in Great Britain, and at 30 to 40 per cent. in Prussia.

[2] There were 167,395 cwt. of wool sold altogether in Prussia in 1858, at prices varying from L.17, 5s. down to L.4, 19s. per cwt.

Posen. A marked difference exists between the eastern districts of the province of Posen, where proprietors as well as cultivators of land are Poles, and its northern and western parts. In the latter an improved system of occupation and cultivation has been introduced by German purchasers, and their imported foremen and labourers. In the Polish districts the rule of letting a farm for three years prevails, and with it the most slovenly and exhausting practices of husbandry. Rye in the first year, and oats in the next, and occasionally a crop of peas in the third or fallow year; that is the rule of Polish farms, large or small.

Brandenburg. Mr Albert Thaer, whom the Germans proclaim as the great regenerator of their husbandry, has left a lasting memorial of his practice and theory in the present high condition of farming in Brandenburg, where his example and teaching (1804 to 1828) were most closely observed and followed, and where sandy deserts are since his days covered with abundant crops. Careful cultivation of the potato, very extensive sheep-breeding, and marling of the soil, are characteristics of Brandenburg agriculture. Barley and rye are the principal grains produced. The soil possesses too little solidity for wheat and mangel-wurzel, and the climate is too dry for turnips. Mr Albert Thaer's sheep produced wool of such exquisite delicacy that they attained the highest prices yet known; and this pre-eminence has been strenuously kept up by his followers. The wool of the province of Brandenburg is reckoned the best in the world. In its turn, the stimulus given to sheep-breeding could not but improve the general condition of the land. If the number of sheep has doubled since 1816, the appearance of this sandy desert has also been completely transformed. The state keeps a model herd at Frankenfelde.

Pomerania. The system of farming in Pomerania consists, like that of Mecklenburg, in laying down the land to grass during three out of every seven years. The farms are mostly very large, and cultivated in a steady, old-fashioned manner.

Silesia. Silesia has the most extensive sheep-breeding in Prussia. Taking the whole acreage of this province, 1⅞ sheep is reckoned to every acre. Above 70,000 cwt. of wool (second only to that of Brandenburg) and L.3000 worth of rams are sold annually. Prince Lichnowsky's herds in Kuchelna are the largest and best of all. The old staple produce of Silesia, viz., flax, has almost ceased to exist. The linen had been manufactured for export, principally to Spain; but the King of Prussia having declined to acknowledge Queen Isabella, because her majesty had been raised to the throne by a revolution, the Prussian commerce with Spain lost all the privileges it had formerly enjoyed; and with that the cultivation of flax first slackened, and finally all but ceased. Wheat, rye, rape-seed, and tobacco are grown with advantage, and better modes of cultivation are gradually supplanting the rule of fallow, or the still more frequent absence of all rule.

Saxony. Prussian Saxony owes its agricultural fame principally to the careful production of, so to say, non-cereals, viz., the beet-root for sugar, poppies, chicory, mustard-seed, cumin, anis-seed, tobacco, flax—all very extensively cultivated. The necessity of improved appliances for their production has raised the standard of husbandry in this province generally. There are some farms here (that of Herr Rimpau in Schlanstedt, and Herr Nathusius at Hundisburg) which are conducted with as much order, economy, and intelligence, as any in Great Britain. Of beet-root, the average of a yearly crop has lately been three million cwt. There is very little cattle or horse breeding in this province, the requisite quantity being imported mostly from Oldenberg, and of horses also from Hanover. The ravages of the pneumonia or lung-disease among cattle were more extensive in this than in any other portion of the monarchy; the disease is giving way, however, to innoculation. The wool is inferior to that of Brandenburg and Silesia; but attempts have been effectually made of late to improve the wretched mutton of the country by crossing the wool breed with our Southdowns and Leicesters.

Westphalia As their Saxon forefathers of old, the present cultivators of Westphalia continue growing white crop after white crop, with the slightest possible attention to root crops or to improved implements. Immense farm-buildings, in which nearly all the labourers are lodged and fed, help to preserve to this country its peculiar semi-patriarchal aspect and *régime.* The farmer, whether tenant or proprietor, is mostly too careful of his expenses to fall into actual poverty; but in consequence of the habit of allowing his savings to stagnate in strong boxes, instead of being invested in securities, he never, or very rarely, acquires wealth. A very favourable exception to this general character may be found in the district of Siegen, measuring less than 300 square miles, in which the best systems of irrigating meadows have been carried on with ingenuity for the last thirty years. The same district is remarkable on account of the "Heuberge," a peculiar system of wood-culture, according to which the plantations, after standing eighteen or twenty years, are cut down, the soil first burnt, and then sown with rye; in the following year the young trees are sure to shoot up again of themselves in great abundance, and then are allowed to grow as before for eighteen or twenty years. Westphalia pigs, like all other cattle, are sadly neglected as to nicety of breeding or feeding. Nevertheless, the hams enjoy a world-wide reputation, for which they are indebted to a peculiarity of the farm-houses, the smoke of their immense wood fires, instead of finding its exit through a chimney, being forced along the roof of the spacious hall before its exit, and thus enveloping innumerable hams that are suspended along its rafters.

Rhineland. Agriculture has remained stationary on the borders of the Rhine. It stood highest, perhaps, three centuries ago. But whoever reads Dr Heresbach's amusing book *Rei Rusticæ*, liber iv., published in 1571, giving an account of his Düsseldorf farm, will be struck with the close similitude between what was then and is now the rule. The Code Napoleon, which continues to be law on the left bank of the Rhine, has strengthened the habit of equally subdividing the soil among all the children of the testator; a habit which seems to belong to the Franconian race everywhere, and which that law has sanctioned rather than created. In the hilly districts bare and exhausting fallows are adhered to; in the plains a continuance of as exhausting white crops. More attention begins to be paid to the cultivation of wheat. Rape-seed, flax, tobacco, cardoons, and latterly also the sugar-beet, are cultivated for sale and manufacture. Drainage and the creation of new meadows is changing the aspect of the country; and although this province keeps a larger stock of cattle in proportion to its acreage than any other, yet on the whole but little attention is paid to breeding.

Farm distilleries. In the dry and light soil of Brandenburg and other eastern provinces, the potato is undoubtedly a better root-crop than either turnips or mangel-wurzel. For any over-production of potatoes a distillery seemed to offer the only advantageous employment; and hence the number of private distilleries. No less than 20,000,000 cwt. of potatoes are used for distilling every year. The excise-duty on distilled liquors produces about L.750,000 a year.

In Saxony, Silesia, and a few other localities, many farmers devote their best fields to the production of the sugar beet-root. There were 101 sugar factories in 1851, using 11,109,728 cwt. of beet-root; and latterly that number has increased by about one-fourth. It is intended to raise the present excise-duty of 7½d. to 9d. per cwt. of beet-root. When this increase will have been effected, the protection afforded to home-grown sugar against the competition of colonial sugars will be but trifling. Those among the owners of sugar factories who have a sufficient command of capital, declare that they do not fear that competition any longer.

Woods and forests.

About one-fifth of the entire acreage of Prussia, viz., 14,406,945 acres, is covered with wood. Of this number, again, two-fifths belong to the state, and the rest to private individuals or corporations. The former are in admirable preservation; large tracts of the latter class have suffered much by the greediness and maladministration of their owners. A law for the better protection of woods and forests is now in preparation. A good deal of unproductive land has of late years been converted into green forests by means of a special fund voted by parliament. The proceeds from the state forests were very trifling until lately, if we take the average of the whole country, viz., only 2s. 3½d. per acre; but the rapid development of the mining industry, of railways, &c., begins to improve the value of wood property. Rhineland possesses the greatest amount of woodland, and next to it Silesia.

General Board of Agriculture.

As in England in former days, a board of agriculture, presided over by a member of government (*Landwirthschaftliches Ministerium*) conducts the agricultural affairs, so far as they regard the state. One of its principal cares is the improvement of agricultural education throughout the country. For this purpose, five agricultural colleges for gentlemen, managers, and large farmers have been founded, viz., Möglin in Brandenburg (commenced by Mr A. Phaer, and the property of his family), Eldena in Pomerania, Proskan in Silesia, Waldau in Prussia proper, and Poppelsdort in Rhineland; the latter four being entirely endowed by the state. Besides these, there are 23 agricultural schools for smaller occupiers of land.

V. *Land Cultivated and Uncultivated in* 1855.

PROVINCES.	Gardens, Orchards, and Vineyards.	Land under Tillage.	Meadows.	Pasture Land.	Woods and Forests.	Uncultivated Land.	Total.

---

[1] It would be an error to suppose, on account of the large numbers in this column, that each of these Lilliputian plots really represent the property of a man. In the Land-Register (or *Kataster*) a separate number is given to every plot of land which belongs to a different proprietor from the surrounding ones, without reference to the circumstance, that ten or twenty or more of these different plots may belong (as they usually do) to one owner. Yet it is a striking fact, that two-thirds of all pieces of land in the Rhenish province should be under 3½ acres, and that the average size of all other holdings in the same province put together does not reach 20 acres.

VIII. *Number of Horses and Cattle in* 1855.

1858	40	9	27	2	24	0	19	2

Vineyards. The grape ripens occasionally in the neighbourhood of Berlin. There are vineyards also, producing very sour wine, in Silesia and the Saxon province. But the principal production of wine takes place in the Rhenish province, where 30,902 acres of land are devoted to this laborious cultivation along the banks of the Rhine, the Ahr, the Moselle, the Nahe, and the Saar. In the years 1857 and 1858 the vintage was both excellent and plentiful, after nine years of continued disappointment. The number of hogsheads of white and red wine, in the vintage of 1857, is officially given at 260,259⅗.

Minera The mineral wealth of Prussia is immense, particularly in Silesia and Rhineland, but cannot be said to have been more than touched upon as yet. The increase of production during the last years alone, since capitalists have been induced to turn their attention towards its development, would show the capabilities of this branch of industry. There existed, at the close of 1857, 89 mining companies with a paid-in capital of L.15,600,000, 50 of them working foundries and mines generally, and 39 coal-mines alone: 499 coal-mines were in activity. The quantity of coal produced in 1851 was 4,413,000 tons, and in 1857 it reached 9,003,817 tons. Besides coals, lignite, or *Braunkohle*, is extensively found in the tertiary formations of Brandenburg and Saxony. This lignite (being a bituminous vegetable mass less completely carbonized) has a heating effect equal to one-third of that of coals. Applying that ratio to the produce of lignite in 1857,—viz., 3,467,500 tons,—we receive an addition of 1,155,833⅓ to the above quantity of coals extracted from the earth. This would give us 10,159,650⅓, or a little more than one-seventh of the production of coal in Great Britain. In spite of this enormous difference, the rapid progress of the last years has already raised Prussia to the second rank among coal-producing countries.

Iron. The increase has been yet more rapid in iron ore,—viz., from 2,820,000 cwt. in 1851 to 18,939,844 cwt. in 1855, and 28,739,936 cwt. in 1857. The demand, however, being even greater than the supply, foreign iron came in abundantly,—viz., 2,600,000 cwt. in 1855, and nearly double as much, viz., 4,161,357 cwt., in 1857.

Zinc, lead, copper, &c. Almost all zinc manufactured in the world is of Prussian, and especially of Silesian origin: 4,377,789 cwt. of zinc ore were obtained in 1857. The lead-mines of Commern in Rhineland promise one day to become the most productive in Europe; at present (1858) their produce is 648,183 cwt.[1] Westphalia and Silesia also contain some lead-mines of no importance. Copper is found most in the Saxon province; its entire production does not exceed 1,308,465 cwt.

Value o mineral produc The entire production of coals in the year 1857 represented a value (taking the average price paid at the mouth of the pit) of L.3,522,802; that of lignite, L.393,330; of iron ore, L.359,605; zinc ore, L.457,808; lead ore, L.257,662; copper ore, L.93,614; other minerals, L.27,000;—sum total,

---

[1] This sum represents the *entire* produce of lead in Rhineland; about 25,000 cwt. must be deducted from it for a few very insignificant mines besides Commern.

L.5,111,821. The value of mineral produce had increased 63 per cent. from 1854 to 1857; 113,134 miners were employed in extracting the above mineral produce in 1857, to 89,254 in 1854. And what is more curious still, each one of them, in the former year, produced on an average the value of L.45; whilst in 1854 the value of each workman's labour had only amounted to L.35. The number of women and children finding employment was 195,930.

Salt. The production of salt is 2,771,720 cwt., four-fifths of which are produced from works belonging to the state. Besides the above, beds of rock-salt begin to attract much notice,—one at Stassfurth, 7 miles from Magdeburg, discovered a few years ago, already produces 250,000 cwt. of nearly pure salt.

Precious stones, &c. Amethysts, chrysoprases, and agates are found in Silesia; alabaster in Saxony; marble principally in Silesia and Westphalia; excellent porcelain near Halle; fossil amber among the lignite or *Braunkohle;* and sea-amber on the coast of the Baltic between Dantzic and Memel, partly washed on the shore during the storms together with the sea-weed, partly pulled up with long hooks, and partly dug out of the earth. About 600 cwt. is the yearly produce of sea-amber.

Mineral springs. Prussia contains 108 mineral springs, among which Salzbrunn and Warmbrunn in Silesia, and the sulphur-baths of Aix-la-Chapelle, are most famous.

Iron-works, &c. There are about 265 high furnaces now in operation. The production of raw iron amounted to 5,858,072 cwt. in 1855, and to 7,072,766 in 1856; cast-iron amounted to 2,265,827 in 1855, and to 2,354,649 in 1856; bar-iron and sails to 4,810,000 in 1855, and to 5,333,730 in 1856. It may be interesting to compare the average price of British iron on its arrival in Prussia with that of Prussian iron at the works, during the three years 1865–57:—

			Zollverein Duty.		Total.	
	s.	*d.*	*s.*	*d.*	*s.*	*d.*
Scotch raw iron on its arrival in Prussia	5	$1\frac{2}{5}$	1	0	6	$1\frac{2}{5}$
Prussian raw iron at the works	...		...		6	$2\frac{2}{5}$
Welsh bar-iron on its arrival in Prussia	10	$10\frac{9}{10}$	4	6	15	$4\frac{9}{10}$
Prussian bar-iron at the works	...		...		15	$5\frac{3}{10}$
British sheet-iron on its arrival in Prussia	14	$10\frac{1}{5}$	9	0	23	$10\frac{1}{5}$
Prussian sheet-iron at the works	...		...		21	$11\frac{1}{2}$

The chief rcason for this comparative cheapness of British iron is briefly this: that in one only out of ten or more cases in Prussia are coal and iron met with together, and in all others they require an expensive carriage to and fro.

Silver is not found anywhere in a pure state, but extracted out of its accompanying metals (lead and copper), particularly in the mines near Eisleben, Luther's birthplace. Those among our readers who have travelled in Prussia may remember occasionally coming upon thaler-pieces with the inscription, "*Segen des Mansfelder Bergbaues.*" The entire native production does not exceed L.122,190 worth of silver. Gold is similarly extracted to a trifling amount (L.867).

The value of all iron-works,—lead, copper, silver, gold, brass, smelt, nickel, arsenic, antimony, alum, and vitriol works put together,—was L.11,971,658: the number of men employed in these works, 59,510; of women, 124,441.

Manufactures. The centres of manufacturing industry in Prussia are,—Berlin, which may be considered at present as the second among the manufacturing towns on the Continent; parts of Westphalia and the Rhenish department of Dusseldorf, and some districts in Silesia.

The manufacture of iron occupies above 40,000 persons in Prussia. In steel, especially cast-steel, the Prussians bid fair to surpass all other nations: we name the towns of Solingen, Essen, Hagen, Remscheid, and the districts of Siegen, whose admirable spath-ironstone offers advantages enjoyed by no other steel factories. Sword and knife blades and guns are manufactured in Solingen and in the Thuringian city of Suhl; guns also in Potsdam. Berlin has risen to celebrity by the neatness of its cast-iron mouldings, and yet more latterly by its engine-foundries, one of which, that of Herr Ad. Borsig, sold 500 locomotive engines for railways in four years.

The manufacture of cotton goods has found its way into Prussia only within the last few years, and does not nearly suffice for home consumption. In 1857, 701 factories occupied 76,700 workmen on 2061 hand-looms, and 16,827 looms worked by machinery. That of linens, on the contrary, has an old-established fame. Spinning flax continues a favourite occupation in the winter evenings, and produces more yarn on an aggregate, even now, than spinning-machines. Of hand-looms also, worked in leisure hours, there are still 300,000, against 204 weaving establishments provided with machinery. Silesian linen is considered the best in the world for lightness and elegance of design; Westphalian or Bielefeld linen for its strength. Excellent damask is also made in the Saxon provinces. Wool has now almost ceased to be worked by hand. There were nearly 60,000 spindles at work in 1857; also 796 cloth factories, with 8227 workmen. Rhineland, Silesia, and Brandenburg are prominent in this branch of industry, the export of the former being principally to the United States. To render Prussia, a silk-producing country was, as our readers already know, one of Frederick the Great's favourite ideas, and it is now again a hobby of modern economists; but German summers being usually too short for a double crop, the raw material of other countries must needs continue to be cheaper. Accordingly, almost all silk is imported for manufacture. Eleven and a quarter millions of yards of silk, of mixed articles, and of velvets, make up the amount of annual exportation; and twelve millions are sold for home consumption. The principal factories exist in Rhineland, producing about six-sevenths of the above quantity; others in Berlin. The capital also contains the largest silk-dyeing establishments. The art of dyeing in Turkish red is an important branch of industry in the two sister cities of Elberfeld and Barmen, averaging 90,000 lb. a week. In Rhineland, principally along its western frontier, raw leather is extensively prepared. Taw-factories are to be found in the neighbourhood of Magdeburg. The glove trade was introduced by French Protestant immigrants at the end of the seventeenth century, and continues to flourish among their descendants in Berlin. The paper factories of Rhineland and Westphalia have lately begun to export largely. Among the 115 glass-works in Prussia, two are justly famed,—one of Zechlin in Brandenburg for chemical apparatuses, and that of Count Schaffgotsch at Schreiberhau in Silesia for what is so universally admired under the name of Bohemian glass, now in a great measure the produce of this excellent establishment. The beer of Prussia, as German beer altogether, is lighter, and more appropriate perhaps to that climate, than that produced in Great Britain. There were no less than 7226 breweries in 1855,—a number, alas! even exceeded by that of distilleries, viz., 8006; of which, however, 1665 are employed in the distillery of spirits of wine. There are 22 houses in the city of Cologne all pretending to distil the famous *eau-de-Cologne,* besides that of its original inventor, Jean Marie Farina, 23 Zülichsplatz. The sugar-factories on farms were mentioned before. Among the sugar-refineries, one,—viz., that of Messrs Vom Rath, Joest, and Carstanjen at Cologne,—is considered the most extensive on the Continent; and the different charges to the state, in the shape of customs, excise, taxes, &c., are rated at L.150,000 a year. The consumption of home-grown and imported tobacco is very great, and can be but inadequately represented by the number of tobacco and cigar factories, viz., 711. German printing used to excel more by quantity than by quality; but Berlin (with Leipzic) has retrieved the honour of the country which first invented that noble art. Berlin also excels by its lithographic establishments, furniture, and general upholstery, and its wool-mosaic, which has rendered Berlin wool a subject of considerable trade to foreign parts. Berlin porcelain also preserves its ancient reputation,—the largest factories being those of Schumann and the royal one. As a general rule, and with very few exceptions, Prussian manufactures are dependent upon Prussian capital. One of these exceptions is the grand plate-glass and mirror factory of Aachen (or Aix-la-Chapelle), which belongs to a French company called St Gobain.

Commerce and navigation.

In all commercial affairs Prussia has almost entirely ceased to exist as a separate state, her special interests having blended in those of the Zollverein, under which head all matters relating to export and import will be fully treated. Only a portion of goods being objects of trade enter the Prussian dominions, or leave them by Prussian seaports, or along the frontiers touching upon countries not belonging to the Zollverein. Again, a portion only of the imported articles remains in Prussia, the rest travelling across the country into foreign or Zollverein states. Generally speaking, the Prussian seaports export corn and timber, and import coals, iron, and salt. According to the best sources of information, the amount of all more notable goods imported into Prussia in 1857 (although not of course for Prussian consumption only) may be calculated as follows:—

	Cwt.
Coals	12,040,338
Raw-iron generally	4,161,357
Wrought-iron, steel, &c.	1,852,809
Copper and brass, unprepared	92,671
Flax, hemp, and tow	390,755
Hemp-seed, linseed, and rape-seed	1,111,155
Aloe, gall-nut, resin, &c.	526,136
Logwood	391,407
Soda	107,598
Potash, &c.	114,978
Oil in casks	208,197
Cocoa-nut oil, palm oil, and spermaceti	288,244
Train oil	106,517
Pitch, tar, &c.	138,652
Hides	217,223
Charcoal	186,276
Salt	959,959
Wool	251,661
Raw cotton	327,205
Cotton yarn, wadding, &c.	393,756
Linen yarn and linen	69,514
Tobacco in leaves	213,834
Unrefined sugar	315,334
Coffee and cocoa	704,243
Tea	21,161
Rice	440,098
Wine, cider, &c	165,269

The total amount of the above goods, together with divers others not here enumerated, was 27,025,669 cwt. Also,—

	Bushels.
Wheat	3,200,285
Rye	3,371,052
Oats, buckwheat, and spelt	600,009
Barley and malt	339,897
Beans, pease, &c.	177,285

The following list gives the number of sea-going vessels which entered or left the Baltic ports in 1857:—

Flags.	Entered.		Left.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Prussian flag	3974	761,610	3880	737,950
Other flags	4559	823,012	4561	826,434
Total	8533	1,584,622	8441	1,564,384

In these numbers the coasting trade has not been included, which is carried on by smaller vessels, above 500 in number, and with an aggregate burden of about 16,000 tons. Stettin, Stralsund, Königsberg, and Dantzic are the most frequented ports.

The abolition of the British navigation laws would have given a far greater impulse to ship-building in the Prussian ports, did not the high protective duties afforded by the Zollverein to the native iron enhance the price of this indispensable metal. Only 271 sea-going vessels were built in the three years 1855 to 1857, leaving 77 on the stocks at the end of that year. An improvement is, however, traceable in the number of Prussian vessels participating in the traffic between Prussia and British ports, as will be seen from the following official list:—Number of Prussian vessels entering British ports in 1855, 1205; tonnage, 278,350: in 1856, 1238; tonnage, 296,362: in 1857, 1353; tonnage, 319,196. Number of Prussian vessels quitting British ports in 1855, 1302; tonnage, 286,404: in 1856, 1395; tonnage, 326,162: in 1857, 1561; tonnage, 354,412. The total number of Prussian sea-going vessels, not including the coasting trade, was 953 vessels, of 278,251 tons in 1854, 29 of them steamers; and 1033 vessels of 326,569 tons in 1857, 63 of them steamers; showing an increase of 80 vessels, and 48,318 tons. During this period 42 vessels had been sold into other countries, and 113 had been lost at sea. A new and most salutary stimulus to navigation in these parts was given by the treaty of 14th March 1857, in which the King of Denmark renounced the sound dues for the payment of sums apportioned to the amount of shipping of each country. If little advantage has been taken as yet (1858) of this dearly-bought liberty of the seas, the reason is to be found in the distress occasioned by the great commercial crisis of 1857.

Roads.

The miserable condition, and in some parts the absence of roads, in the beginning of this century, has given way to plentiful and excellent means of communication. Turnpike roads, of which Frederick II. had professed so great a horror, were never seriously taken in hand until the general peace of 1815; and since that time no trouble or money has been spared to render the net-work complete. In 1857 Prussia possessed 14,331 miles of first-rate macadamized and mostly turnpike roads, or about one mile of macadamized road to every 7·76 square miles of land; 5992 of which belong to trusts or corporations, and 8340 to the state. The gross yearly cost of keeping up the latter is L.330,000, of which sum L.195,000 are covered by tolls, &c.

Prussia possesses 26 railroads belonging to private companies, and 5 belonging to the state. The aggregate length of railways (finished in 1858) is 2725 miles, which makes 1 mile of railway to every 193 square miles of land.[1] The increase since the end of 1848 has been of 938 miles, or of 84 per cent. The railways of the state have cost the sum of L.10,726,665. For the rest, L.16,516,380 were raised by ordinary shares, and L.13,746,120 by preferential shares and debentures; making a total expenditure of L.30,262,500 for private railways, and L.40,987,500 for all railways together. Seventeen more railways are to be finished by the end of 1860, 938 miles in length, which will increase the length of railways in Prussia to 3663½ miles. All state railways lie in districts where the expense of construction has been in too unfavourable a proportion to the traffic of the line. Thus the principal state railway—that to Königsberg, 289 miles long—required works of gigantic dimensions in the crossing of the Vistula and the Nogat, and passes through districts but thinly peopled. Yet the necessary sums were cheerfully voted on grounds of general utility. The lines belonging to the state consequently are not paying ones.[2] The condition of the private lines, on the other hand, is highly favourable, producing an average dividend on the paid-in capital (on an average of all the private lines together) of no less than 7 per cent. The Magdeburg-Leipsic line ranks first, with 24 per cent.; then the Upper Silesian and Magdeburg-Halberstadt line, with 13 per cent.; the Berlin-Stettin line, with 9$\frac{7}{12}$ per cent.; the Berlin-Anhalt line, with 9 per cent.; the Cologne-Minden line, with 8$\frac{2}{3}$ per cent.; the Rhenish line, with 6 per cent. If the nett profits, therefore, more than double the average of the nett profits in Great Britain, the gross receipts were 71$\frac{1}{2}$ per cent. of British receipts (in 1857), those on Prussian lines being L.1887 per mile. The aggregate traffic was of 12,982,000 passengers, and 170,518,000 cwt. of goods.

---

[1] In Great Britain, the ratio was given as 1 mile of railway to every 65; and in France, 1 to every 213 square miles.

[2] The above-mentioned Eastern Railway produced a nett profit of 2·17 per cent. in 1857.

Banking system.

The Bank of Prussia (*Preussische Bank*) was instituted by Frederick the Great in 1765, and the following years,—first, by a loan of L.1,200,000, and then by directing that all deposits of tribunals and other public offices should be paid to one of the bank's offices, and deposited there at an interest of 3 per cent., and at a week's notice. The operations of the bank soon became extensive, and so profitable that its directors were enabled to repay the loan in the reign of Frederick's successor. After a partial suspension of payment in 1806, the bank resuscitated in 1815, and has ever since been increasingly beneficial. In 1846 the capital of private shareholders was admitted to the amount of L.1,500,000, and leave given to issue bank-notes, one-third of the amount to be covered by bullion. By an act passed May 6, 1856, the bank has been permitted to double its capital, and to increase its circulation of notes very considerably. The maximum of circulation in 1857 was L.11,055,600, and nearly L.15,000,000 in 1858. The bullion collected reached the sum of L.6,000,000 in 1857, and L.10,849,836 in 1858. Deposits were nearly L.3,000,000 at the close of the latter year. Originally the bank had two offices, in Berlin and Breslau; gradually the number has increased to 103. There are eight joint-stock banks in the monarchy licensed to issue notes at the rate of L.150,000 each. The number of private banks and money-offices (some of them very insignificant) is 512.

Army

In Prussia the army is in a certain sense co-extensive with the people. All men capable of bearing arms are expected to co-operate, if need be, to the country's defence. We shall have to speak,—1*st*, Of the *standing army*, with its reserve; 2*d*, Of the *landwehr* or *militia*; and 3*d*, Of the *landsturm*. The standing army consists of two distinct classes, to the higher of which belong the commissioned officers, who are gentlemen by birth and education and the non-commissioned officers or sergeants; to these commissioned and non-commissioned officers the military service is a profession for life, as in any other army in the world. The privates of the standing army, on the contrary, are recruits of one, two, and three years' standing, and comprise all able-bodied youths in the country, excepting the only sons of poor widows, or others similarly situated. They enter the army at the age of twenty, are drilled during three years, and then during the two following years are subject to be called back to their regiments regularly for a few weeks' exercising, and, if necessary, for war. By means of this reserve, the standing army can be increased by two-thirds of its numbers at three days' notice. One class of Prussians is, however, privileged to serve in the ranks only one year, after which they are at once placed on the lists of the reserves; to it belong all young men of superior education without distinction of birth or parentage, who are able to pay for their own sustenance, uniform, &c. If they prove themselves capable, and if they are admitted by the officers, these young "Freiwillige," as they are called, afterwards enter the landwehr, with a commission as landwehr officers. All the rest, at the expiration of five years from their first entrance into the army, become privates or sergeants in the landwehr. This land armament or militia is composed of all the drilled men during a further term of thirteen years, after they have quitted the standing army and reserve. Six years out of these thirteen constitute the first *Aufgebot* or levy, and the rest the second *Aufgebot*. The first Aufgebot is called under arms every three or four years for several weeks' practice in manœuvring. All the landwehr lists, accoutrements, &c., are kept in such perfect order that a fortnight's notice will suffice to equip them ready for war. After attaining his thirty-ninth year a Prussian is free from military service, excepting in cases of extreme need, when the king is by law empowered to call upon every man, up to his fiftieth year, to rise and take arms for the defence of the district in which he lives. This last-named formidable levy would, if ever called out, constitute the landsturm.

The education of officers and sergeants for their military profession is attended to as carefully as in most other well-organized armies, by military and cadet schools for the infantry and cavalry, as well as for the artillery and engineers. No officer can, however well qualified, enter a regiment, even with a royal commission in his pocket, unless the officers of that regiment declare their willingness to receive him as a man of unimpeached honour. Sergeants are picked men from the rank and file, induced to remain in the service by the certainty of being provided for by the state when disabled by wounds or old age to serve any longer. The privates of the Prussian militia or landwehr make better soldiers on the whole, at any given time, than those of the standing army. This may seem a paradox, as the latter are actually under arms, whilst the former return to their banners, each from his civil employment. But in the landwehr you have men perfectly drilled, and in the prime of life, against recruits who have scarcely outgrown their boyish years. Of the officers of the landwehr the same cannot be said. One year's training, and after that a few weeks of field practice, with long intervals between, do not enable the majority of those even in the position of subalterns to act independently of officers of the standing army. A partial reform of the militia institution has therefore been considered necessary. The landwehr, instead of being combined into separate regiments, is to form additional (4th, 5th, and 6th) battalions of each regiment in the standing army. With this view, the staff of officers in the latter is being greatly augmented, in order that every regiment may be able to grant a sufficient number of them to their respective landwehr battalions, whenever the militia may be called out.

The standing army, with its reserve and the militia (we may omit the landsturm in our further remarks) is divided into 9 army corps, 1 of which is formed by the household troops, and each of the 8 others belonging to one of the princes of the monarchy. The first army corps-d'armée is stationed in Prussia proper, the eighth in Rhineland. An army corps is divided into 2 divisions, of 2 brigades each. Again, it consists of 4 regiments of infantry, 4 regiments of cavalry (the guards only have 6 cavalry regiments), 1 regiment of artillery, 1 rifle battalion, and 1 detachment of pioneers. The Prussian infantry consists of 144 battalions of the standing army, including 10 rifle battalions, and 116 of landwehr, of the first aufgebot. Nearly all regiments contain 3, but some of them have 2 battalions of 1000 men each. In the cavalry the numbers are,—152 squadrons of the standing army, and 144 of landwehr, 4 squadrons to a regiment, and each squadron of 120 horses in times of peace, 160 horses in its war strength. The artillery also is divided into regiments, 9 in number, and consisting of 16 batteries each, with 5 additional, making 149 batteries in all. There are in time of peace 216 guns, fully equipped, belonging to the horse artillery (a corps first instituted by

Frederick the Great), 648 to the foot artillery, and 10 to the fortress companies,—874 in all.

Without further enumerating pioneers, &c. &c., we shall now state the numbers of the Prussian army. Its real numbers in times of peace amount to 161,000 officers and men. In case of war, this can be instantly increased to an effective force of 357,000. Sealed orders for completing this number ("mobilizing," as it is termed) always lie ready in the office of every officer holding a separate command. In warlike contingency, a telegram would direct him to open the sealed packet, and then the work of producing his troops, complete in every respect, must be done in a fortnight's time. In addition to the above number, there would further be 246,000 men armed and equipped for doing the service in the interior, ready for any emergency.

Thus the Prussian army, in case of war, can at any time be raised to the formidable number of 603,000 men, all perfectly drilled,—a popular army, such as no other country possesses, unassailable for defence in a cause of undoubted necessity and justice. Many people were of opinion that this popular institution contains elements which might prove dangerous to the state, or at least not be available under all circumstances and for every purpose alike. The latter of these doubts seems to be well-founded; for it may be asserted that for any prolonged war merely for dynastic interests,—in fact, for any war not absolutely forced upon the country,—an army so composed would be no suitable instrument. But there is no fear of this militia being turned to purposes subversive of public order and tranquillity. When the king called out part of the landwehr in the midst of the revolutionary commotion of 1848, they assembled under their banners as willingly as they would at any other time. Exception is also frequently taken to the rawness of these troops, which must, it is believed, place them in disadvantages if opposed to elder men. It would seem that there must be advantages as well in the greater youthfulness of part at least of the Prussian troops (for the landwehr are grown-up men), for it is a historical fact, that the greatest general of modern days, on being asked which of the three armies, the Russian, Austrian, or Prussian, he would most like to command, declared unhesitatingly, "They are all three very good, but I should prefer commanding the Prussian army."[1]

The pay of a Prussian soldier in times of peace is very small, and his keep as economical as possible. The private receives twopence-worth in kind, and 3¼d. in money, or 5¼d. a day, which is even less than the Frenchman's pay of 6d. per day, and only ⅖ths of an English private's pay. For officers of the lower grades also the emoluments are so trifling that it would appear almost impossible for any of them to clothe and feed themselves without some private fortune. A great many of them, however, manage to exist upon that pittance, without any such extra help, proud of their profession and the social distinctions it confers upon them. Nevertheless, the cost of the military establishment swallows up nearly one-fourth of the entire annual expenditure of the state.

Prussia keeps federal garrisons (alone or jointly with Austria and other German states) in the fortresses of Luxemburg, Maintz, and Rastadt. Her own fortresses are numerous, and some among them of the first magnitude. Towards France, Saarlouis holds the first line of defence, then Jülich, Wesel, *Cologne*, and *Coblentz*, with *Ehrenbreitstein.* Towards Russia the line of fortifications has been more attended to of late, but is far from complete yet. Here the fortress of *Posen* forms the principal bulwark against aggression. Königsberg on the Baltic will soon equal it in strength. Further on, the line of the Vistula is defended by Thorn, Culm, Grandenz, and *Dantzic;* and the Oder line by Neisse, Cosel, Glatz, Glogau, Cüstrin, *Stettin;* the Elbe line by Torgau, Wittenberg, and *Magdeburg.* Besides these, Pillau, Colberg, and Stralsund must be mentioned as maritime defences, and Schweidnitz and Silberberg as defences against Austria. Among this large number, six are of first magnitude (in italics), nine other of second, and the rest of third rank.

Naval defences.

The total absence of a fleet had placed the coasts of Prussia and Germany at the mercy of their Danish neighbour in 1848. Hence the general desire in Prussia that the coasts should be adequately protected, and that there should be a small number of armed vessels of the best description, to prevent a third-rate power from again seriously damaging the trade of their large and mighty country. Accordingly, Dantzic and Stettin, Stralsund and the island of Rügen, received additional fortifications on the sea-side. These places were not, however, considered as sufficiently good harbours; and the Prussian government purchased the Bay of Jahde, a waste stripe of coast, from the Grand Duke of Oldenburg, which is eventually to become the naval port of Prussia. The Prussian flotilla at present consists of 2 frigates, 3 corvettes, 3 steamers of 12 guns each, 3 schooners, 42 gunboats, a transport vessel of 292 guns altogether, 90 officers, 1300 sailors, and a battalion of marines, with 622 officers and men.

Public education.

Prussia has strenuously laboured to earn the reputation of being inhabited by a better-educated people than any in the world. "Every child shall be taught to read and write and to make sums:" such is the principle of Prussian law—by its parents, or if not, by professional masters and mistresses, and at the expense of every parish. The state providing,—1*st*, Normal schools and examiners for the schoolmasters, no schoolmaster being licensed to teach publicly who has not passed the prescribed examination; 2*d*, Supplementary means, where the parish funds do not suffice, in which cases the government has the appointment, or a share in it; and 3*d*, The strong hand of the law, if parents disobey the country's injunction to send their children to school. In 1855, out of 2,943,251 children of school age in all stations of life then living in the monarchy, 2,758,472 went to elementary schools. The number of schools was 24,292; of schoolmasters, 31,467; of schoolmistresses, 1523. The pay of all elementary schoolmasters and schoolmistresses together throughout the monarchy, from private and government funds, amounted to L.900,000 in 1857, which is more by L.64,500 than the sum-total was in 1852. In this the contributions of government are only L.60,000. A Prussian schoolmaster or mistress receives, on an average, L.28, 13s. a year of fixed salary, besides lodging and some other emoluments and occasional helps. The cry for increased salaries is becoming very loud (the government board is now, 1858, granting relief at the rate of L.5,500 a year), and there seems to be a growing inclination to enforce an improvement by law.

Normal schools (*Seminare*) were first instituted in 1820; their number is at present 39 for the education of masters, and 4 for mistresses. Of these, 43 were Protestants, and 15 Roman Catholic. There are 2398 pupil teachers educated in them, at a cost to the state of L.29,731, or about L.12, 15s. each.

Another higher class of schools, also entirely supported by parishes (or nearly so), is comprised under a variety of names, beginning from middle-schools (*Progymnasien*), and rising up to *Höhere Bürgerschulen* or *Realschulen.* Their number was 512 for boys, with 2394 teachers and 72,653 scholars; and 382 higher schools for girls, with 2015 teachers and 54,753 scholars in the year 1852. The instruction in these schools is grounded principally on mathematics, and not on the classics, and is carried on with a constant and almost exclusive view to those practical occupations in after-life for which most of the pupils are brought up. The highest of this class, called *Realschulen* (mathematical schools, as we should call them), 56 in number, have the right of giving certificates to their pupils on leaving. The number of gymnasia or classical schools is 131, with about 1000 ordinary masters, 700 assistants, and 34,000 pupils. Only a few of these gymnasia have accommodation for the pupils; among them is the famous old school of Pforta, in the Saxon province, founded in 1543. These are mostly ancient foundations, and self-supporting; nearly all the rest require very large assistance at the hands of government, if they are not entirely supported by it.

---

[1] These words fell from the lips of the late Duke of Wellington in an after-dinner conversation in the year 1849.

The Prussian universities, alike in every respect to those of the rest of Germany, are divided into four "faculties," according to the principal branches of learning; the first of theology (subdivided in Breslau and Bonn into an evangelic and Roman Catholic faculty), the second of jurisprudence, the third of medicine, and the fourth of philosophy, which comprises all studies, without exception, not taught under any of the above heads. The number of students is subject to considerable fluctuations. The following table for 1856–57 can be taken as tolerably near the average of the last years:—

VII. *Attendance at the different Prussian Universities*, 1856–57.

Universities.	Divinity.		Jurisprudence.	Medicine.	Philosophy.	Total Number of Students.	Number of Students in 1836.	Professors.	Yearly Expenditure.
	Evangelical.	Roman Catholic.							
Berlin	292	...	694	265	319	1570	1832	149	L.19,228
Bonn	61	211	213	96	247	828	835	71	16,365
Breslau	83	203	202	138	158	784	875	72	14,074
Halle	445	...	125	47	79	696	777	74	13,508
Königsberg	94	...	123	86	46	349	430	60	12,600
Münster	...	301	...	...	148	449	255	16	...
Greifswalde	35	...	46	101	55	137	204	41	10,284
Total...........	1010	715	1403	733	1052	4813	5208	483	...

On a comparison of these numbers with those of previous years,—for instance, 1836,—we find that in almost every university, and particularly in the faculties of divinity, a decided diminution has taken place, the only exception being the university of Münster, and these just in its theological faculty. The cause of this lies mainly in the circumstance, that all learned professions are at present overstocked in Prussia, and that the progress of industrial and commercial activity in the country carries many young men straight from school into practical life. As for the exception (viz., Münster), it is explained by the decided predilection evinced by Romanist bishops for a place where their students should be free from contact with any other but their own doctrine.

The highest literary body in the country is the Academy of Sciences at Berlin, instituted by Frederick I. in 1706, after an elaborate plan of the great Leibnitz, much encouraged (though in imitation of the Parisian model) by Frederick II. Its publications are of the highest order both in physical science, mathematics, &c., and in classical philology, geography, &c. Its membership is much coveted in Prussia, as well as in other countries: the present numbers are,—50 German members, 20 foreign members, 185 corresponding members. There is a Royal Academy of Arts in Berlin, and a Royal Academy for Painting at Dusseldorf. Veterinary schools, deaf-and-dumb schools, and blind asylums abound.

Law.

The criminal law of the country was entirely codified and proclaimed as one and the same for the whole monarchy, in 1851. Not so the common law; in this there exists a considerable diversity, according to provinces and districts. In parts of Pomerania, and near Ehrenbreitstein, for instance, the old laws of the Empire still exist; local customs prevail unimpaired in other districts; in the greater portion of Rhineland the French code has remained in force, and is much esteemed for its distinctness and simplicity; and in the rest of the monarchy the landrecht (essentially instituted by Frederick the Great, but promulgated only in 1794) holds its sway, except where more modern statutes have modified its tenets.

The law acknowledges no inequality amongst Prussians. All special jurisdictions are by law abolished, excepting the military code for persons in actual military service, and a special tribunal for students of universities, before which, however, only matters of discipline are brought.

The highest court of the monarchy is the Ober Tribunal in Berlin, to the decrees of which distinguished body the judges of other courts invariably refer in questions of precedents. The next class of tribunal is formed by twenty-two *Appellations-Gerichte*, to which parties may appeal from the judgments of the *Stadt-* or *Kreis-Gerichte*. The former of these exist in the five most populous towns; and of the latter there are 238, or nearly one to every administrative *Kreis* or district in the realm. Assizes, with trial by jury (instituted since 1848 throughout the monarchy, and imitating rather too closely the French instead of the English model), are held four times a year, in eighty of the towns.

Constitution.

The kingdom of Prussia is a limited monarchy. We have seen above that on February 6, 1850, King Frederick-William IV. solemnly took the oath required by the new law of the country, "to observe faithfully and unswervingly the constitution of his country and monarchy, and to govern in accordance with it and the laws." Thus the new order of things was inaugurated; and the constitution (called, after the day of its publication, that of the 31st of January 1850) has existed ever since; painfully, it is true, and subject to several modifications, but beneficently, if we consider what the country would have been without it, and hopefully, too, for the future. The usual form and character of continental constitutions is well known to our readers, and on the whole, it is adhered to in the Prussian fundamental law as now in force; we will therefore extract those points only which merit special attention. The king is inviolable and irresponsible. The signature of a responsible minister is necessary for the validity of every act of government. His majesty, the ministers, and all civil servants of the state, are required to swear an oath on the constitution; also the members of parliament, but not the army, whose oath is to the king only. Parliament consists of two houses,—the Herrenhaus (literally House of Lords), and the House of Representatives (Abgeordneten). In the composition of the Prussian House of Lords, which now numbers a little more than 200 members, four elements are mixed up,—birthright, dignity, nomination, and, finally, election. By right of birth, seats in this house belong to 51 persons in all—viz., the princes of Hohenzollern, the heads of 14 ancient mediatized families, whose possessions lie within Prussia, and some other princes, counts, and lords of extensive patrimony; to this number of hereditary peers the king can add new lords at his pleasure, as in England. There are four members in virtue of official dignity, each occupying one of the mediæval high dignities of Prussia proper, which have outlived the reforms of modern days. The princes of the blood take their seat in the house for life, of course. Of real life-peers there are at present 31 in the house, law-advisers of the crown, and others. *Lastly*, the right of election (subject to his majesty's approval of the elected candidate) is granted to the universities, to certain large towns, and in each province to three bodies of noblemen who are landed proprietors—viz., 1*st*, Counts; 2*d*, Noblemen of considerable property; 3*d*, Noblemen, and others, of ancient landed property; each of these classes electing a life-peer, and presenting him for the king's approval. The Lower House consists of 352 representatives of the people, returned by a peculiar kind of double election which we will elucidate in a few words. The franchise being extended to every man twenty-five years old (who has not lost the right of voting in the parish elections), the electors first of all meet in their respective parishes, divided into three classes, according to property. Each class of electors then choose, not the member, but a man of confidence, who is now called a *wahlmann*, within the parish. On a later day these men of confidence assemble at the town appointed for polling, and return a member for the electoral district, every Prussian thirty years old being eligible for this distinction.

The constitution accords to the houses of parliament the following fundamental rights, without which, indeed, it would be worthless:—1*st*, The right of originating laws, as well as deliberating upon such as have been proposed by the crown, no law being valid without the assent of both houses; 2*d*, The right of voting the yearly budgets; 3*d*, Of investigating by commissions any public matter; 4*th*, Of accepting or rejecting, before ratification, every commercial treaty, and all such conventions with foreign powers which may in any way affect the financial obligations of the country. No member of parliament can be arrested or put on his trial without leave given by the house to which he belongs. The Upper House is not permitted to propose amendments to the budget, but must accept or reject it as a whole. The Lower House is elected for three years. Both houses are annually convoked by royal summons; the usual period is about New-year.

Provincial and other assemblies.

Besides this general parliament (*Landtag*) Prussia still possesses some antique assemblies of Stände for each province and district, which have been mentioned in our historical introduction. Their deliberations extend to local matters only; and besides these, they have the management of certain local funds. It is probable that they will soon make room for local elective bodies differently constituted.

Government.

The king's cabinet consists seven of ministers, viz.:—1. Of Foreign Affairs; 2. Of the Interior; 3. Of Finance; 4. Of Justice; 5. Of War; 6. Of Commerce, Trade, and Public Works; 7. Of Church Affairs, and Public Education. Besides these, the cabinet contains a president, or even, as at present, two presidents, without special office. Not belonging to the cabinet are—the minister of the Royal Household, and the president of the Board of Agriculture. The government of the interior is entrusted under the minister to eight presidents of provinces (*Ober-Präsidenten*); under each of them to *Regierungs-Präsidenten*, or presidents of departments; and under these again to *Landräthe*, or commissioners of districts. These *Kreise* or districts correspond to our hundreds; their number is 335.

The management of the woods, forests, &c., forms part of the functions of the minister of finance. The minister of commerce, trade, and public works, is responsible also for the general post-office. In the bureaucratic country of Prussia, the most dreaded public office, the object of a profounder awe than either the king, or laws, or police can command, is the *Ober-Rechnung-Kammer*, or General Board of Accounts, to whose radamanthine scrutiny every official account of money, without exception, has to be submitted.

Prussia never was and never can be a rich country.[1] Economy, not to say parsimony, and strictest order alone, have preserved a firmness to Prussian credit, even in the times of great calamity, such as few other states possess, and enabled her to furnish means for the exigences of war and for national progress in times of peace. The country's debt, which Frederick-William III. had brought down to the trifling sum of L.3,750,000 in 1806, had risen to L.43,125,000 during the disasters and triumphs of war following that year. But ever since 1815 it continued steadily decreasing under the careful hands of that monarch, who paid off no less than L.18,825,000 during the twenty-five remaining years of his reign. In order to give every security to the native and foreign holders of Prussian stock, he declared, on the 17th January 1820, that no new loan should be raised for the state without the consent and under the guarantee of an assembly of representatives of the people. Accordingly, no new loan was made until 1848, since when, every succeeding parliament has listened but too indulgently to the increasing demands on the country's purse by the king's ministers, some of them very useful (as, for instance, for the Eastern Railway, mentioned above), others of a more doubtful nature. In 1851 the public debt had already increased to L.28,892,832; in 1855, to L.36,415,292; in 1856, to L.37,177,726; in 1857, to L.38,038,745. There seems now to prevail a decided inclination to stop in this headlong progression; indeed the year 1858 shows already a diminution of about 1¼ million pounds sterling. The public credit of these securities never suffered to any considerable extent during the late years of revolution and panic, either within the limits of the country or without. Besides this debt, for which interest is paid, another debt of L.2,488,852, paying no interest, should be mentioned in this place,—*i.e.*, the convertible paper-money of the state. The property of the state in woods and forests, &c., from which profit can be made, is officially calculated at L.12,832,704. Taxation is by no means light in Prussia, and almost in the same unfavourable proportion as the public debt, the taxes of the country have increased in an exorbitant degree. The *direct* taxation comprises,—1*st*, A land and house tax, worth about 1½ million pounds. 2*d*, Income-tax, paid by all whose income is above L.150 a year, classified under thirty heads, and so arranged as to be a little below 3 per cent. for each class. The highest amount of income-tax paid in Prussia is L.1080, corresponding to an income of L.30,000 a year. This tax produces to the state about L.450,000. 3*d*, The *Classensteuer*, a misnomer, by which is understood another and older kind of income-tax, averaging about 2 per cent., laid upon those persons or householders whose yearly income does not reach L.150. These are divided into three classes. From this tax are exempt the poor, children, and old people; soldiers, &c., on active service; all foreigners; and, lastly, the citizens of larger towns, in consideration of the *octroi* (see below). Its result to the state is about 1¼ million. 4*th*, A tax on trades (*Gewerbe-Steuer*), producing about L.450,000 a year. 5*th*, A railway-tax of very modern date, raised on the yearly dividend in a progressive ratio, which produces about L.100,000. In the chapter of *indirect* taxation, custom-house and transit dues rank first in productiveness, viz., L.1,800,000; then follows the malt-tax, with the excise on brandy and beet-root sugar, worth 1½ million pounds sterling; the stamp-duty contributes L.600,000; the *octroi*, or *Mahl und Schlachtsteuer*, raised at the gates of 83 Prussian towns on cereals and butcher's meat, about L.350,000; turnpike roads, nearly L.200,000; tolls and port dues, about L.140,000; shipping dues, L.65,000.

---

[1] All calculations regarding the wealth of a given population must needs be of a precarious nature. This want of exactitude has not diminished since the introduction into European states of income-taxes, but rather increased. We prefer, therefore, to take the lists of 1850 (the year previous to the introduction of the income-tax) to all the more specious accounts to be found in recent statistical publications. In that year the number of rate-payers was 4,950,454. Of this number only 19,988, or 0·4 per cent., appear from official lists to have been rated as enjoying an income of more than L.180; 159,985, or 3·23 per cent., between L.60 and L.180 a year; 359,564, or 7·26 per cent., L.30 to L.60; 835,537, or 16·88 per cent., L.15 to L.30; 3,575,380, or 72·23 per cent., L.3, 15s. to L.15. Only 180,000 heads of households, therefore, or persons living singly throughout Prussia, or 4 per cent. of all rate-payers, had an income above L.60 in the year 1850. Another fact worth mentioning in this place, perhaps, is this: taking the larger estates (*Rittergüter*) of the Prussian monarchy all together, the mortgages officially registered against them amount to four-fifths of their *rated* value, or to two-thirds of the *selling* price which they would fetch in the market.

The yearly expenditure of the state for raising these sums of direct and indirect taxation, which amount in the aggregate to above eight and a half million pounds sterling, is only L.780,000. There are two state monopolies still in existence, both contrasting strangely with the general and financial progress of the country, the one raising the price of one of the first necessaries of life, the other pandering to an unruly love of gain. We mean the monopoly on salt, which produces L.1,350,000, at a cost of no less than L.480,000, and which is relaxed in its severity only in favour of cattle-salt; and the state-lottery, whose evil effects on the lower classes the government have in vain fancied to conjure by the high price of lots, and the slowness of its operations (only four times a year),—a monopoly in the strictest sense of the word, as all other public gambling, *roulette*, &c., is prohibited in the Prussian dominions. The wages of this sin to the state are L.200,000, gained at a trifling cost of L.15,000. The share of state profit in the operations of the Bank of Prussia was about L.150,000 latterly.

The *Domänen* (woods, forests, &c., according to our nomenclature) are royal estates which Frederick-William III. gave over to the country in that same memorable decree of 17th January 1820, which we had occasion to mention above. They are administered by the minister of finances. A sum of L.385,965 is deducted first of all from their rental, for the maintenance of his majesty and the royal family, and all the expense of their different households. It should be remarked that this sum of L.385,965, although partaking of the nature of a civil list, is not subject to an annual vote by the legislature, but is deducted at once from the receipts under the form of a standing and inalienable charge. The Prussian Chamber of Representatives, without ever calling into doubt this prerogative of the crown, which is, moreover, sanctioned by the constitution; and without claiming the power of reducing that sum, have, however, willingly taken it upon themselves to *raise* it (March 1859) by L.75,000, in consideration of the altered value of money.

Having premised these few preliminary explanations of Prussian finance, we now give the budget of 1858, contracting a number of its minuter details:—

RECEIPTS.

1. Minister of finance		L.11,890,954
Woods and forests, &c. (*minus* L.385,965 for crown, as above)	L.1,409,061	
Direct taxation	3,813,549	
Indirect taxation	4,847,139	
Salt monopoly	1,355,625	
State lottery	197,115	
Share of profit in the Bank of Prussia, &c. &c.	162,900	
Carry forward		L.11,890,954
Brought forward		L.11,890,954
2. Minister of commerce, trade, and public works		5,192,590
General post-office	L.1,706,070	
Electric telegraph	105,751	
Mines, &c	2,077,019	
State railways, &c	1,262,789	
3. Minister of justice		1,445,084
4. Minister of the interior		117,772
Prisons	L.78,459	
5. General Board of Agriculture		222,972
Studs of Trakehnen, &c	L.65,443	
6. Minister of church affairs and public education		13,738
7. Minister of war		45,725
8. Minister of foreign affairs (consular and passport dues)		1,345
9. Receipts from Hohenzollern		31,286
Total of receipts		L.18,961,466

EXPENDITURE.

1. Public debt			L.1,979,977
Interest		L.1,341,895	
Sinking fund		570,598	
2. Parliament			36,250
3. Council of ministers (*Staats ministerium*)			37,153
4. Minister of foreign affairs			127,092
Diplomatic service		L.66,817	
Consular service		16,189	
5. Minister of finances			2,828,961
a. General expenses		L.957,176	
b. Special expenses		1,871,785	
Woods, forests, &c.	L.574,799		
Direct taxation	152,811		
Indirect taxation	628,389		
Salt monopoly	487,577		
State lottery	16,515		
6. Minister of commerce, trade, and public works			4,974,810
a. General expenses		L.798,318	
b. Special expenses		4,176,491	
Post-office	L.1,409,456		
Mines	1,585,636		
Electric telegraphs	69,571		
State railways, &c. &c.	1,081,902		
7. Minister of justice			1,698,738
8. Minister of the interior			813,724
Gaols	L.326,729		
Police	296,430		
Statistical and meteorological office only	2,716		
9. General Board of Agriculture			337,130
Studs of Trakehnen, &c.		L.95,721	
10. Minister of church affairs and public education			539,647
Affairs of the Evangelic Church		L.61,071	
Affairs of the Roman Catholic Church		11,312	
Universities		73,068	
Grammar and mathematical schools (*Gymnasien* and *Realschulen*)		47,144	
Elementary schools		66,817	
Science and art		30,936	
11. Minister of war			4,549,120
12. Board of Admiralty			92,159
13. Expenditure on Hohenzollern			28,885
14. Special credits for 1858			917,820
Total of expenditure			L.18,961,466

The budgets of Prussia have, like her public debt, been rapidly increasing of late years. The first budget published by authority was that of 1821. It amounted, in receipt and expenditure, to L.7,500,000, and was followed by as moderate ones during the reign of Frederick-William III. In 1844 it had risen by rather more than L.1,000,000, and in 1850 it was L.13,695,353. From 1851 to 1854 there were successive deficits to cover. The balance was re-established in 1855, when it was L.16,774,168; it was L.17,829,610 in 1856; L.18,036,346 in 1857; and L.18,961,466 in 1858. If we distribute the expenditure equally over its entire population at given epochs, we shall find that the contribution of each inhabitant would have been, in the years from 1821 to 1844, 11s. 6·1d.; in 1849, 16s. 2·4d.; in 1852, 17s. 7·2d.; in 1855, 19s. 6d.; in 1856, 20s. 7·2d.; in 1857, 20s. 9·4d.; in 1858, 21s. 8·4d. (G. v. B.)

Prussia.

PRUSSIA, a province of the kingdom of that name, forming its most easterly portion, bounded on the N. by the Baltic, E. by Russia, S. by Poland and the province of Posen, and W. by those of Brandenburg and Pomerania. The division into E. and W. Prussia, historically of considerable importance, is now only used as a convenient way of designating the two chief parts of the province, as they have long ceased to be two distinct provinces. Extreme length from E.N.E. to W.S.W. about 300 miles; greatest breadth, 150; area, 24,967 square miles. The surface is in general low, but not by any means flat; for a chain of hills, on an average 300 or 400 feet high, extends in a curved line from the vicinity of Goldap, near the Russian frontier, to that of Marienburg on the Vistula. Of these hills, and of the whole province, the highest point is the Hasenberg, near Landsberg, to the S. of Königsberg, which attains the height of 725 feet. Along the coast of the Baltic there are on the west of the Vistula many well-wooded hills, from 150 to 500 feet high; but to the east of that river the shores are perfectly flat, except where shifting sand-hills break the level. The Gulf of Dantzic and the arms of the sea called the Frische and the Kurische Haff, indent the coast of this province. The largest rivers are the Vistula, flowing northwards from Poland into the Gulf of Dantzic by several arms; the Passarge from the south and the Pregel from the east, flowing into the Frische Haff; the Memel, the Mange, and the Dange, flowing westwards from Russia into the Kurische Haff. Of lakes the province contains a great number, distributed in three principal groups. The largest of these groups lies near the eastern extremity of Prussia, between the basins of the Pregel and Vistula, in a valley more than 300 feet above the sea, and it includes Lake Spirding, 45 square miles in extent. Another group of lakes, smaller in size and lower in elevation, lies between the Passarge and the Vistula; while the third group lies to the west of the latter river. There are several extensive swamps and moors, especially towards the north-eastern extremity of the province. The soil is in general very fertile; and no other province in the kingdom has such an extent of good land. About two-thirds of the surface is good land; the rest being mostly sandy ground. Of the whole area of the country, 6,930,985 acres consisted in 1852 of arable land; 204,240 of gardens, vineyards, &c.; 2,955,726 of meadows and pastures; 2,513,460 of forests; and 3,368,667 of waste land. Wheat is one of the principal crops raised, especially in the low country along the Vistula, Pregel, and Memel; rye is also raised of such excellence as to be much exported. Besides these, most of the common crops are grown in the province. Prussia contained in 1855, 461,504 horses, 987,023 horned cattle, 2,642,268 sheep, 17,143 goats, and 520,512 swine. Manufactures are not very extensively carried on in the province, the whole number of hands employed being 128,568; less in proportion to the population than there are in any other province of the kingdom. The only important mineral found here is iron, which is plentiful in various places; but on the shores of the Baltic amber is obtained in greater abundance than anywhere else in the world. The trade is considerable; three of the chief seaports in the kingdom, Dantzic, Königsberg, and Memel, being in this province. Corn, timber, hides, tallow, and other articles are exported. Though there are numerous excellent educational institutions in the province, the percentage of those receiving instruction is considerably under the average of the kingdom. There is one university, that of Königsberg; 8 normal seminaries; 14 gymnasia, with 188 teachers and 4207 scholars; 6 progymnasia; 42 middle schools; and 4417 elementary schools, with 5059 teachers and 338,516 scholars. In regard to religion, the most of the inhabitants belong to the Evangelical Church. Besides these, who are 1,885,256 in number, there are 703,252 Roman Catholics, 1204 of the Greek Church, 12,693 Mennonites, and 34,351 Jews. For administrative purposes the province is divided into the governments of Königsberg, Gumbinnen, Dantzic, and Marienwerder. The Æstui, who are described by Tacitus as a nation largely employed in collecting and trading in amber, seem from this fact to have been the original occupants of this province. After this, however, the history of the country is for a long period involved in almost total obscurity. Bands of Goths and Scandinavians in the third century, and of Letts and other nations in the sixth, settled here, and mingled with the original inhabitants. The Prussians, as they were called from a very early period, resisted for a long time all the efforts made to convert them to Christianity. St Adalbert, who was the first to attempt it, suffered martyrdom in 997. Bruno, a monk, who renewed the attempt, met with a similar fate; and neither the persuasions of these and similar missionaries, nor the sword of the kings of Denmark and Poland, professedly drawn in the service of the church, could induce the Prussians to abandon a religion believed to be inseparable from their freedom, till the Teutonic Knights in 1230 entered the country. Little by little this crusade proved successful, and the knights possessed themselves of the whole country; the grand-master establishing his seat at Marienburg in 1309. On the introduction of Christianity, many Germans settled in the country; thriving towns rose; and commerce began to extend itself. But the prosperity of the country excited the envy of the Polish sovereigns, who proceeded to open hostilities, which resulted in the battle of Tannenberg in 1410, so decisively against the Teutonic order that Prussia became then actually, and afterwards also formally, a fief of the Polish crown. The contest, however, did not cease here; and the fortune of war still proving adverse to the knights, they were obliged by the peace of Thorn in 1466 to give up West Prussia entirely to Poland, retaining the eastern portion as a fief from the crown. The office of grand-master afterwards became hereditary in the Brandenburg family; and in 1525 the Margrave Albert, having adopted the Protestant faith, had the office changed into a dukedom. The victory of Warsaw, gained in 1656 by the Elector Frederic William over the Poles, enabled him to get rid of the Polish supremacy over East Prussia; and the western part of the province was restored to the kingdom of Prussia by degrees in the successive partitions of Poland. It was from this province that Frederic III., the elector of Brandenburg, took, in 1701, the title of King of Prussia. Pop. (1855) 2,636,766.

Prynne.

PRYNNE, William, an English lawyer, noted alike for his pamphlets and his punishments, was born at Swainswick, near Bath in Somersetshire in 1600. After graduating at Oxford in 1620, he became an outer barrister of Lincoln's Inn, was well read in English law, and was filled with zeal for gospel doctrine and morality. On his arrival at the Inn he became a follower and admirer of the Puritan lecturer Dr John Preston, who, finding Prynne hot-spirited and zealous to a degree, put him forward on occasions where a considerate man would not have dared to appear. Struck by certain scandals of the time, real or imaginary, especially by that of play-acting and masking, Prynne saw good, in 1632, to assail them in his *Histriomastix*, or "Player's Scourge." Dr Peter Heylin, "lying Peter," as men sometimes call him, who had an old grudge at this zealous lawyer for "confuting some of his doctrines," was busy reading this book with the most intense interest, and by Laud's direction, making excerpts from it. This being done, Laud charged Attorney-General Noy to prosecute Prynne before the Star Chamber. This Noy did with rigour, and the young barrister was sentenced to pay a fine of L.5000, to stand in the pillory, to lose his ears, to suffer perpetual imprisonment, and to witness the burning of his

Histriomastix by the common hangman. During his residence in prison he continued writing and publishing fulminations against the bishops, "calling them Luciferian lord bishops, execrable traytors, devouring woolves, with many other odious names not fit to be used by a Christian," thinks old Wood. (*Athen. Oxon.*, vol. iii. Bliss.) He published his pamphlet, *News from Ipswich*, in 1637, in which he fell foul of bishops and archbishops, and roused afresh the indignation of Laud; on which he was again before the Star Chamber; was fined again in L.5000; to lose his ears the *second* time, having had them "sewed on again" before; to be branded on both cheeks S. L. (seditious libeller); and to be perpetually imprisoned in Caernarvon Castle. A great crowd, we are told, witnessed the spectacle in the Old Palace Yard on the 30th June 1637, "silent mainly and looking pale" (Carlyle's *Cromwell*, vol. i.), with Prynne addressing them from his exalted position, defying Lambeth, with Rome at the back of it, to prove to him that these practices were according to the law of England. It was against Laud and his "surplices at Allhallowtide" that Prynne had offended, and not against the law of England. He was borne to Caernarvon; thence to Mount Orgeuil Castle; when, on November 7, 1640, there came an order from "the blessed House of Commons" (so termed by his party) for his releasement. "On the 28th of the same month," writes Anthony à Wood, "they triumphantly entered, being then accompanied with thousands on foot and horseback, and in coaches, with rosemary and bays in their hats, crying 'Welcome home, welcome home! God bless you! God be thanked for your return!' &c., to the great contempt of authority and justice." Prynne was elected member of Parliament for Newport in Cornwall, shortly after. Here he kept up his original assault against the bishops, and played an important part in the trial of Archbishop Laud. In the Long Parliament he was zealous in the Presbyterian cause; and when the Independents gained the ascendancy, he opposed them strongly. On his being excluded from the House by the "purging" which it received, he attacked Cromwell and his party with so great bitterness that he was again thrown into prison. He was shortly afterwards released, and took to his favourite exercise of the pen. Being raised to his seat after Cromwell's death, he was active in furthering the Restoration, and was chosen keeper of the records of the Tower, with a salary of L.500. He died in 1669.

He was a most voluminous writer, but we fear more than the *Histriomastix* is now altogether unreadable. He wrote *Records of the Tower*, in 3 vols., and *Parliamentary Writs*, in 4 vols.; and presented his works, nearly 200 of them in all (a list of which is to be found in Wood's *Athenæ Oxonienses*, vol. iii.), in 40 vols., to the Lincoln's Inn library.

PRYTANES (πρυτάνεις), in Grecian antiquity, were the presidents of the Senate, whose authority consisted chiefly in assembling the Senate, which for the most part was done once every day. The Senate consisted of 500, fifty senators being elected out of each tribe; after which lots were cast to determine in what order the senators of each tribe should preside, which they did by turns, and during their presidentship were called *prytanes*. Their period of office was termed a *prytany* (πρυτανεία), and the building in which they held their meetings was called the *prytanium* (πρυτανεῖον). However, all the fifty prytanes of the tribes did not govern at once, but one at a time, namely for seven days; and after thirty-five days another tribe came and presided for other five weeks; and so of the rest

PRZEMYSL, a town of the Austrian empire, in Galicia, on the San, 51 miles W. of Lemberg. It is walled, and is one of the most ancient towns in the country. On a hill in the vicinity stand the remains of an old castle, once the residence of the princes of Przemysl, which was in the tenth century an extensive Rusmak principality The town is the seat of a Roman Catholic and of a Greek bishop; and it contains several fine Gothic churches, the chief being the Roman Catholic cathedral, with some interesting paintings and old military trophies. There are also here several schools and an hospital. Leather, linen, and woollen articles are manufactured. Pop. 8650; more than the half being Jews.

PRZIBRAM, a town of the Austrian empire, in Bohemia, on the Litawka, 35 miles S.S.W. of Prague. It is a small place, and chiefly remarkable for its mines of silver and lead, the former producing upwards of 1500 lb. annually. There are here smelting-houses and paper-works. Pop. 5638.

PSALMANAZAR, George, the fictitious name of a pretended Formosan, a person of learning and ingenuity. Born in France about 1679, he was educated in a free school, and afterwards in a college of Jesuits, in an archiepiscopal city, the name of which, as likewise those of his birth-place and his parents, are unknown. Upon leaving the college, he was recommended as a tutor to a young gentleman, but soon fell into a mean and rambling life, which involved him in disappointments and misfortunes. His first pretence was that of being a sufferer for religion. He procured a certificate that he was of Irish extraction, that he had left that country for the sake of the Catholic faith, and was going on a pilgrimage to Rome. But being unable to purchase a pilgrim's garb, and observing one in a chapel dedicated to a miraculous saint, which had been set up as a monument of gratitude by some wandering pilgrims, he contrived to take away both the staff and the cloak; and, thus accoutred, he begged his way in fluent Latin, accosting only clergymen or persons of figure, whom he found so generous and credulous that, before he had gone 20 miles, he might easily have saved money, and put himself in a much better dress. As soon as he had got what he thought sufficient, however, he begged no more, but viewed everything worth seeing, and then returned to some inn, where he spent his money as freely as he had obtained it. Having heard the Jesuits speak much of China and Japan, he started the wild scheme, when he was in Germany, of passing for a native of the island of Formosa; and what he wanted in knowledge he supplied by a pregnant invention. He formed a new character and language on grammatical principles, which, like other oriental languages, he wrote from right to left with great readiness; and he planned a new religion, and a division of the year into twenty months, with other novelties, in order to give credit to his pretensions. He now assumed the character of a Japanese convert to Christianity, travelling for instruction, with an appearance of greater wretchedness than even that of common beggars. He then entered as a soldier in the Dutch service; but, being still desirous of passing for a Japanese, he altered his plan to that of being an unconverted heathen; and at Sluys, Brigadier Lauder, a Scotch colonel, introduced him to one James, chaplain to the forces, who, with the view of recommending himself to the Bishop of London, resolved to carry him over to England. At Rotterdam, some persons having put shrewd questions to him that carried an air of scepticism, he took one more whimsical step, which was to live upon raw flesh, roots, and herbs, thinking that such strange food would remove all scruples. The Bishop of London patronized him with credulous humanity; and Psalmanazar found a large circle of friends, who extolled him as a prodigy. Yet there were some who entertained a just opinion of him, particularly Dr Halley, Dr Mead, and Dr Woodward; but their endeavours to expose him as a cheat, only made others think the better of him, especially as these gentlemen were supposed to be unfriendly to revelation. In this instance, at least, easiness of belief was no great evidence of penetration. He was employed to translate the Church Catechism into the Formosan language, which was examined, approved, and laid up as a valuable manuscript; and the author, after writing his well-known *History of Formosa*, was rewarded and sent to Oxford to study what he liked, whilst his patrons and opponents were learnedly disputing at London on the merit of his work. The learned members of the university were no better agreed in their opinions than the savans of London; but at length the sceptics triumphed. Some absurdities were discovered in his *History* of such a nature as to discredit the whole narration, and saved him the trouble of an open declaration of his imposture, which, however, he owned at length to his private friends. For the remainder of his life, his learning and ingenuity enabled him to procure a comfortable support by his pen; and he was concerned in several works of credit, particularly *The Universal History*, and *The Complete System of Geography*, 1747. He published anonymously an *Essay on Miracles*, by a Layman, which enjoyed considerable reputation. He lived irreproachably for many years, and died some time in 1763. There was printed after his death, *Memoirs of ——— ———, commonly known by the name of George Psalmanazar, a reputed native of Formosa, written by himself*, London, 1765.

PSALMODY, from the Greek ψαλμος, *the art* or *act of singing psalms*. The earliest music of the Psalms is not now known. The modern Jewish psalmody is by no means the same in all their synagogues in different countries. Psalms were sung by the primitive Christians, but there are no data to show the precise nature of the melodies. St Augustin (lib. x. Confess. cap. 33) says, "De Alexandrino Episcopo Athanasio sæpe mihi dictum commemini, qui tum modico flexu vocis faciebat sonare lectorem psalmi, ut pronuncianti vicinior esset quam canenti." St Athanasius was made bishop of Alexandria in 326. Of the Ambrosian and Gregorian chants of the fourth and sixth centuries time and change seem to have spared little more than the tonalities. In Roman Catholic church services the psalmody varies according to the particular occasion; and so also in some Protestant churches. Many of the psalm-tunes now in general use in Protestant churches were composed in the time of Luther, or not long afterwards, for the Protestant congregations which then began to spread over the European continent. Others of these tunes are the productions of various Protestant musicians in later times. Amongst the authors of these more recent tunes we find the names of some of the Bachs, of Handel, and several other eminent German composers. Psalm-tunes are for voices only, or for voices accompanied by the organ, or for voices accompanied by different instruments; others for a single voice alone, or accompanied, and so on. (G. F. G.)

PSALMS, THE BOOK OF, received its name, Ψαλμοί, in consequence of the *lyrical* character (ψάλλω, *to touch* or *strike a chord*) of the pieces of which it consists, as intended to be sung to stringed and other instruments of music. Another name, *Psalter*, was given to this book, from the Greek ψαλτήριον, the *stringed instrument* to which its contents were originally sung. The Hebrew title (*tehilim*) signifies *hymns* or *praises*, and was probably adopted on account of the use made of the collection in divine service, though only a part can be strictly called songs of praise, not a few being lamentations and prayers. In Ps. lxxii. 20, we find all the preceding compositions (Ps. i.–lxxii.) styled *prayers of David*, because many of them are strictly prayers, and all are pervaded by the spirit and tone of supplication. All the best judges, as Lowth, Herder, De Wette, Ewald, Tholuck, and others, pronounce the poetry of the Psalms to be of the *lyric* order. "They are," says De Wette (*Einleitung in die Psalmen*, p. 2), "lyric in the proper sense; for among the Hebrews, as among the ancients generally, poetry, singing, and music were united, and the inscriptions to most of the Psalms determine their connection with music, though in a way not always intelligible to us. Also as works of taste these compositions deserve to be called lyric. The essence of lyric poetry is the immediate expression of feeling; and feeling is the sphere in which most of the Psalms move. Pain, grief, fear, hope, joy, trust, gratitude, submission to God, everything that moves and elevates the heart, is expressed in these songs. Most of them are the lively effusions of the excited susceptible heart, the fresh offspring of inspiration and elevation of thought; while only a few are spiritless imitations and compilations, or unpoetic forms of prayer, temple hymns, and collections of proverbs." We shall consider in their order the *Titles* of the Psalms, their *Authors*, their *Collection and Arrangement*, and their *Canonicity and Use*.

Titles.—All the Psalms, except thirty-four, bear superscriptions. According to some, there are only twenty-five exceptions, as they reckon a title in all the Psalms which commence with it. The authority of the titles is a matter of doubt. By most of the ancient critics they were considered genuine, and of equal authority with the Psalms themselves, while most of the moderns reject them either in whole or in part. They were wholly rejected at the close of the fourth century by Theodore of Mopsuestia, one of the ablest and most judicious of ancient interpreters. They are received, on the other hand, by Tholuck and Hengstenberg in their works on the Psalms. Of the *antiquity* of the inscriptions there can be no question, for they are found in the Septuagint. They are supposed to be even much older than this version, since they were no longer intelligible to the translator, who often makes no sense of them. Their obscurity might, however, have been owing not so much to their antiquity as to the translator's residence in Egypt, and consequent ignorance of the Psalmody of the Temple service in Jerusalem. At any rate the appearance of the titles in the Sept. can only prove them to be about as ancient as the days of Ezra. Then it is argued by many that they must be as old as the Psalms themselves; for very important traces of the custom of prefixing titles to their songs by Orientals appear in Isa. xxxviii. 9, in Hab. iii. 1, and in 2 Sam. i. 17, 18 (Tholuck's *Psalmen*, p. xxiv.). In 2 Sam. xxiii. 1, and Num. xxiv. 3, there is strong proof of the usage, if, with Tholuck, we take the verses as inscriptions, and not as integral parts of the songs, which most hold them justly to be from their poetical form.

The following considerations militate against the authority of the titles:—1. The analogy between them and the subscriptions to the apostolical Epistles. The latter are now universally rejected: why not the former? 2. The Greek and Syriac versions exhibit them with great and numerous variations, often altering the Hebrew. Could such variations have arisen if the titles had been considered sacred like the Psalms themselves? 3. The inscriptions are occasionally at variance with the contents of the Psalms.

The design of these inscriptions is to specify either the author or the chief singer (never the latter by name, except in Ps. xxxix.), or the historical subject or occasion, or the use, or the style of poetry, or the instrument and style of music. Some titles simply designate the author, as in Ps. xxv., while others specify several of the above particulars, as in Ps. li. The longest and fullest title of all is prefixed to Ps. lx., where we have the author, the chief musician (not by name), the historical occasion (comp. 2 Sam. viii.), the use or design, the style of poetry, and the instrument or style of music. It is confessedly very difficult, if not impossible, to explain all the terms employed in the inscriptions; and hence critics have differed exceedingly in their conjectures.

Authors.—Many of the ancients, both Jews and Christians, maintained that all the Psalms were written by David:

which is one of the most striking proofs of their uncritical judgment. So the Talmudists (*Cod. Pesachim*, c. x., p. 117); Augustine (*De Civ. Dei*, xvii. 14); and Chrysostom (*Prol. ad Psalmos*). But Jerome held the opinion which now universally prevails (*Epist. ad Sophronium*). The titles and the contents of the Psalms most clearly show that they were composed at different and remote periods by several poets, of whom David was only the largest and most eminent contributor. According to the inscriptions, we have the following list of authors:—

1. David, "the sweet Psalmist of Israel" (2 Sam. xxiii. 1). To him are ascribed seventy-three Psalms in the Hebrew text, and at least eleven others in the Septuagint, namely, xxxiii. xliii. xci. xciv. xcix. civ. cxxxvii.; to which may be added Ps. x., as it forms part of Ps. ix. in that version. From what has been advanced above respecting the authority of the titles, it is obviously injudicious to maintain that David composed all that have his name prefixed in the Hebrew, or to suppose that he did not compose some of the eleven ascribed to him in the Septuagint, and of the others which stand without any author's name at all. Of those which the Septuagint ascribes to David, it is not improbable that Ps. xcix. and civ. are really his; and of those which bear no name in either text, at least Ps. ii. appears to be David's. David's compositions are generally distinguished by sweetness, softness, and grace; but sometimes, as in Ps. xviii., they exhibit the sublime. His prevailing strain is plaintive, owing to his multiplied and sore trials, both before and after his occupation of the throne. See Herder's *Geist der Ebr. Poesie*, ii. 297–301; and especially Tholuck (*Psalmen, Einleitung*, § 3), who gives a most admirable exhibition of the Psalmist's history and services. The example and countenance of the king naturally led others to cultivate poetry and music. Of these Psalmists the names of several are preserved in the titles.

2. Asaph is named as the author of twelve Psalms, viz., l., lxxiii.–lxxxiii. He was one of David's chief musicians. All the poems bearing his name cannot be his; for in Ps. lxxiv. lxxix. and lxxx. there are manifest allusions to very late events in the history of Israel. Either, then, the titles of these three Psalms must be wholly rejected, or the name must be here taken for the "sons of Asaph;" which is not improbable, as the family continued for many generations in the choral service of the Temple. Asaph appears from Ps. l. lxxiii. and lxxviii., to have been the greatest master of didactic poetry, excellent alike in sentiment and in diction.

3. The sons of Korah was another family of choristers, to whom eleven of the most beautiful Psalms are ascribed. However, in Ps. lxxxviii. we find, besides the family designation, the name of the individual who wrote it.

4. Heman was another of David's chief singers (1 Chron. xv. 19). He is called the Ezrahite, as being descended from some Ezrah, who appears to have been a descendant of Korah; at least Heman is reckoned a Kohathite (1 Chron. vi. 33–38), and was therefore probably a Korahite; for the Kohathites were continued and counted in the line of Korah.

5. Ethan is reputed the author of Ps. lxxxix. The Ethan intended in the title is doubtless the Levite of Merari's family whom David made chief musician along with Asaph and Heman (1 Chron. vi. 44; xxv. 1, 6). The Psalm could not, however, be composed by him, for it plainly alludes (ver. 38–44) to the downfall of the kingdom.

6. Solomon is given as the author of Ps. lxxii. and cxxvii., and there is no decided internal evidence to the contrary, though most consider him to be the subject, and not the author, of Ps. lxxii.

7. Moses is reputed the writer of Ps. xc., and there is no strong reason to doubt the tradition. But the Talmudists, whom Origen, and even Jerome, follow, ascribe to him also the ten succeeding Psalms (xci.–c.), on the principle that the anonymous productions belonged to the last-named author. This principle is manifestly false, since in several of these Psalms we find evidence that Moses was not the author. In Ps. xcv. the forty years' wandering in the wilderness is referred to as past; in Ps. xcvii. 8, mention is made of Zion and Judah, which proves that it cannot be dated earlier than the time of David; and in Ps. xcix. 6, the prophet Samuel is named, which also proves that Moses could not be the writer.

The dates of the Psalms, as must be obvious from what has been stated respecting the authors, are very various, ranging from the time of Moses to that of the Captivity—a period of nearly 1000 years. In the time of King Jehoshaphat (about B.C. 896), Ps. lxxxiii., setting forth the dangers of the nation, as we read in 2 Chron. xx. 1–25, was composed either by himself, as some suppose, or most likely, according to the title, by Jahaziel, "a Levite of the sons of Asaph," who was then an inspired teacher (see 2 Chron. xx. 14). In the days of Hezekiah, who was himself a poet (Isa. xxxviii. 9–20), we may date with great probability the Korahitic Psalms xlvi. and xlviii., which seem to celebrate the deliverance from Sennacherib (2 Kings xix. 35). In the period of the Captivity were evidently written such laments as Ps. xliv. lxxix. cii. and cxxxvii.; and after its close, when the captives returned, we must manifestly date Ps. lxxxv. and cxxvi.

Collection and Arrangement.—As the Psalms are productions of different authors in different ages, we are led to inquire how and when they were collected. The truth seems to be, as Ewald and Tholuck maintain, that the collection was made not so much with reference to the beauty of the pieces as to their adaptation for devotional use in public worship. When the Psalms were collected, and by whom, are questions that cannot be confidently answered. It is certain that the book, as it now stands, could not have been formed before the building of the second temple, for Ps. cxxvi. was evidently composed at that period. In all probability it was formed by Ezra and his contemporaries, about B.C. 450 (Ewald's *Poet. Bücher*, ii. 205). But in the arrangement of the book there is manifest proof of its gradual formation out of several smaller collections, each ending with a kind of doxology. The Psalter is divided in the Hebrew into five books, and also in the Septuagint version, which proves the division to be older than B.C. 200. The *first* book includes i.–xli.; the *second*, xlii.–lxxii.; the *third*, lxxiii.–lxxxix.; the *fourth*, xc.–cvi.; and the *fifth*, cvii.–cl. These five books may, with some propriety, be thus distinguished:—The first *Davidic*, the second *Korahitic*, the third *Asaphitic*, and the two remaining *Liturgic*.

Various classifications of the Psalms have been proposed (Carpzov, *Introductio*, &c., ii. 132–134). Tholuck would divide them, according to the matter, into songs of praise, of thanksgiving, of complaint, and of instruction. De Wette suggests another method (*Einleitung*, p. 3), into—1. Hymns, as viii. xviii.; 2. National Psalms, as lxxviii. cv.; 3. Psalms of Zion and the Temple, as xv. xxiv.; 4. Psalms respecting the king, as ii. cx.; 5. Psalms of complaint, as vii. xxii.; and 6. Religious Psalms, as xxiii. xci. It is obvious, however, that no very accurate classification can be made, since many are of diversified contents and uncertain tenor.

Canonicity and Use.—The inspiration and canonical authority of the Psalms are established by the most abundant and convincing evidence; and no other writing is so frequently cited in the Scriptures. In every age of the church the Psalms have been extolled for their excellence and their use for pious purposes (Carpzov, *l. c.*, pp. 109–116). Among the early Christians it was customary to learn the book by heart, that psalmody might enliven their social hours, and soften the fatigues and soothe the sorrows of life. They employed the Psalms not only in their religious assemblies, but also at their meals and before retiring to rest.

It may be well here to notice what are called the vindictive Psalms, namely, those which contain expressions of wrath and imprecations against the enemies of God and his people, such as Ps. lix. lxix. lxxix., and which in consequence are apt to shock the feelings of some Christian readers. In order to obviate this offence, most of our pious commentators insist that the expressions are not maledictions or imprecations, but simple declarations of what will or may take place. But this is utterly inadmissible; for in several of the most startling passages the language in the original is plainly imperative, and not indicative. (See Ps. lix. 14; lxix. 25, 28; lxxix. 6.) The truth is, that in reality they are not opposed to the spirit of the gospel, or to that love of enemies which Christ enjoined. Resentment against evil-doers is so far from being sinful, that we find it exemplified in Christ himself. (See Mark iii. 5.) If the emotion and its utterance were essentially sinful, how could Paul (1 Cor. xvi. 22) wish the enemy of Christ to be accursed, or say of his own enemy, Alexander the coppersmith, "the Lord reward him according to his works" (2 Tim. iv. 14); and, especially, how could the spirits of the just in heaven call on God for vengeance (Rev. vi. 10)? See a good article on this subject ("The Imprecations in the Scriptures") in the American *Bibliotheca Sacra* for February 1844.

The following are among the chief exegetical aids for explaining this book:—Poli *Synopsis;* Venema, *Comment. in Psalmos;* De Wette's *Commentar über die Psalmen*, 1836; Rosenmülleri *Scholia in Epit. Redacta*, vol. iii.; Maureri *Comment. Crit. Grammaticus*, vol. iii.; Hitzig's *Comment. und Uebersetzung;* Ewald's *Poet. Bücher*, vol. ii.; Tholuck's *Uebersetzung und Auslegung der Psalmen;* and Hengstenberg's *Commentar ueber die Psalmen.* The last two are excellent.

The principal English works on the Book of Psalms are the translations (mostly with notes) of Mudge, 1744; Edwards, 1755; Fenwick, 1759; Green, 1762; Street, 1790; Wake, 1793; Geddes, 1807; Horsley, 1815; Fry, 1819; French and Skinner, 1830; Noyes, 1831 (Boston, U.S.); Walford, 1837; Bush, 1838 (New York); and numerous commentaries. An excellent work is, Rev. John Jebb, *A Literal Translation of the Book of Psalms, with Dissertations*, Lond. 1846. There is also a tolerably well executed translation into English verse, by E. A. Bowring, Lond. 1858.

PSAMMITICHUS, a renowned sovereign of Egypt, who flourished B.C. 664. (See EGYPT.)

PSELLUS, MICHAEL CONSTANTINUS, a learned Christian of the eleventh century, was by birth a Constantinopolitan of consular rank, and flourished under the Emperor Constantine Monomachus, 1020 A.D. His genius and industry raised him far above the level of his contemporaries; and the celebrated historian Anna Comnena speaks of him as one who had been more indebted for his attainments to his own excellent talents than to the instructions of his preceptors; adding, that having made himself master of all the wisdom of the Greeks and the Chaldæans, he was justly esteemed the most learned man of the age. Thus furnished, he became the chief instructor of the Constantinopolitan youth. He was at the same time the companion and preceptor of the emperor, who became so captivated by the studies and amusements in which Psellus engaged him, that, according to Zonaras, he neglected the concerns of the empire. The Byzantine historians complain, that the emperor, deluded by "the Prince of the Philosophers," the title with which Psellus was honoured, lost the world. Towards the close of his life, Psellus, meeting with some disappointment, retired into a monastery, and soon afterwards died; but the time of his death is uncertain. He was not only the most accomplished scholar, he was likewise the most voluminous writer of his age. He published a great variety of works, both prose and poetical, written with a high degree of eloquence and taste. Besides his *Synopsis Organi Aristotelici*, 8vo, 1597, and his mathematical works; there are sixteen other works which have been printed separately. There are likewise numerous writings of this author still inedited. (For an account of those writings, see Fabricius, and Cave.)

PSEUDO (ψεῦδος, *a falsehood*), is used in the composition of many words to denote *false* or *spurious.*

PSEUDONYMOUS, amongst critics, is an author who publishes a book under a false or feigned name; as *cryptonymous* is given to him who publishes one under a disguised name, and *anonymous* to him who publishes without any name at all.

PSKOV (Germ. *Pleskau*), a government of European Russia, bounded on the N. by that of St Petersburg, N.E. by that of Novgorod, E. by that of Iver, S.E. by that of Smolensk, S. and S.W. by that of Vitebsk, and W. by that of Livonia: length, from N.W. to S.E., 202 miles; greatest breadth, 140; area, 17,705 square miles. The surface is low and very nearly level, having only a gradual slope from the Valdai Hills, in the S.E. of the government, towards the N. and W. Most of the rivers flow in a northeasterly direction, the principal exception being the Düna, which flowing S.W., forms the boundary between this government and that of Smolensk. Though numerous, the rivers are all of small size; the principal being the Velikaia Pskova, Lovat, and Schelon, which are navigable for flat-bottomed boats. The latter two rivers flow into Lake Ilmen in Novgorod, the former two into Lake Pskov, at the N.E. extremity of the government; all discharging their waters finally into the Gulf of Finland. The principal lake is that already mentioned, communicating by a strait with that of Peipus. A great part of the country is occupied with marshes, and the soil is generally of inferior quality; but by dint of careful cultivation and manuring, it is made to produce more corn than the wants of the inhabitants require. The quantity of arable land in the government in 1849 was 3,462,151 acres; of meadow land, 522,425 acres; of wood, 5,760,156 acres; and of waste land, 1,183,105 acres. Wheat is little grown; the chief crops being rye, oats, barley, pulse, &c. Hemp and flax are also raised. In 1849, 15,584,447 bushels of corn and 1,594,839 bushels of potatoes were produced in Pskov. In the same year the government contained 144,720 horses; 226,960 horned cattle; 112,945 sheep; 122,890 swine; and 5460 goats. Game and various other wild animals are found in the forests, and the rivers abound in fish. No minerals of any importance are found in the country; but timber, especially pine, is obtained from the forests. The people are chiefly engaged in agriculture, and manufactures are not extensively carried on. Of these there were in 1849, 112, employing 4057 hands; the most important being the tanneries, 41 in number. Corn, timber, hemp, flax, hides, &c., are exported; while colonial and other produce is imported. The majority of the people are of Russian origin, and belong to the Greek Church; but there are also a few Roman Catholics, Protestants, and Mohammedans. The government contained in 1854 thirty village schools, with 806 pupils. Pop. (1851) 657,283.

PSKOV, the capital of the above government, on the left bank of the Velikaia, about 5 miles above its mouth in Lake Pskov, and 165 S.W. of St Petersburg. In the centre stands the Kremlin or citadel, inclosed by a wall; the middle town, also walled, surrounds this in a semicircular form, beyond which is the great town; the whole being inclosed by a wall 5 miles in circuit. The houses and many of the public edifices are built of wood. Some of the latter are splendid buildings, such as the cathedral and the palace of the archbishop, formerly that of the princes of Pskov. The churches are numerous; and there are also a gymnasium, several other schools, an orphan hospital, and three convents. The manufacture of leather is actively carried on; glass, linen, and sail-cloth are also made. Large markets are held here annually, and there is much trade in the produce of the country. Pskov was in the middle ages an independent town, and carried on a very extensive trade with the Hanse towns. Though much inferior now to its ancient greatness, it is still a large and important place. Pop. 10,842.

PSYCHE (Ψυχή, *breath, the soul*) is represented in later antiquity as the personification of the human soul, and about whom Apuleius (*Met.* iv. 28, &c.) has the following beautiful allegory:—Psyche, the youngest of the three daughters of a king, having aroused by her beauty the jealousy and envy of Venus, that goddess ordered Amor or Cupid to inspire her with a love for the most contemptible of mortals. Amor had no sooner beheld this matchless beauty than he became suddenly enamoured of her. He bore her to some charming spot, where he unseen and unknown visited her every night, and left her when the day began to dawn. Her sisters persuaded her that she embraced some hideous monster under the darkness of the night. To satisfy her curiosity, she arose with a lighted lamp, and beheld to her inexpressible delight the most handsome and lovely of the gods. In her bewilderment of joy and fear, she gazed on him as he slept, when a drop of hot oil fell from her lamp upon his breast. Amor awoke, censured Psyche for her mistrust, and immediately vanished. Her peace was now gone; she attempted in vain to throw herself into a river; she wandered about inquiring for her beloved; when she arrived at the palace of Venus. The goddess retained her as a slave, and imposed upon her the hardest tasks. Amor, who still secretly loved her, brought her invisible comfort and assistance, till Venus, overcome by the gentle obedience and silent attention of the fair slave, granted her immortality, and she became united with Amor for ever.

In this lovely story one can recognise in the misfortunes of Psyche the purification of the soul by suffering and trial before entering upon true and lasting happiness. Psyche is represented by artists as a maiden with the wings of a butterfly. Lafontaine has wrought her story into a pastoral, and Mrs Tighe into a poem. (See vol. li. of Bohn's "Classical Library.")

PSYCHOLOGY. See Metaphysics.

PTOLEMÆUS, Claudius, a great astronomer and geographer. (See Astronomy, and Geography.)

PTOLEMIES, The. See Egypt.

PUBLICOLA was the surname given to Publius Valerius, an old Roman consul. The character of this famous man, as portrayed by Livy and Plutarch, is that of a magnanimous patriot. He was one of those who witnessed the suicide of the ill-fated Lucretia, and who swore over the reeking dagger to avenge the outraged matron. Nor was his oath carelessly performed. He bore a chief part in expelling the Tarquins, and both in his private capacity and after he was elected one of the consuls, he foiled the attempts of the detested family to regain the Roman crown. His zeal became still more disinterested when the death of his colleague, Junius Brutus, left him for some time alone in the consulship. Hearing that the citizens began to be suspicious lest he should suddenly change into a despot, he at once adopted the most decisive measures to disabuse them of this notion. A palatial edifice which he had reared on the Velian Hill was forthwith demolished in a night. The fasces, the insignia of power which were carried before him, were ordered to be henceforth lowered whenever he came into the presence of the people. The most decided and stringent laws were instituted to protect the liberties of the citizens. Among other decrees, it was enacted that every convict should have the right of appeal from the consuls to the people, and that whoever should attempt to set himself up for a king might be slain by any man at any time. For these services Publius Valerius was raised to the very highest place of honour in the state. The surname of *Publicola* ("friend of the people") was conferred upon him and his descendants for ever. He was thrice re-elected to the consulship. On the last of these occasions he had the honour of leading a successful attack against the Sabines, and of entering the city in triumph. The popular favour continued with him to the last; and on his death in 503 B.C., he was buried at the public expense, and lamented by the Roman matrons for ten months.

PUBLIUS Syrus, a celebrated writer of mimes, flourished at Rome about B.C. 42. He was of Syrian extraction, as his name implies, and was brought to Rome as a slave; but his talents having excited the admiration of his master, he received his freedom, and assumed the name of Publius. His farces were much admired, and Julius Cæsar is said to have considered them as superior even to those of Laberius. He interspersed them with moral sentences, many of which have been preserved by later writers. St Jerome states that a collection of these moral sentences was made, and that the Romans employed them as a school-book. They have been collected from various sources, and published several times, along with Seneca or Phædrus; and they have also occasionally appeared separately. The best editions are those of J. C. Orellius, Leipsic, 1822; and of Bothe, in his *Poetarum Latin. Scenic. Fragmenta*, vol. ii., p. 219, 8vo, Leip. 1834.

PUCHBUDRA, a town of British India, in the Rajpoot state of Jodhpoor, in a rich but little cultivated region, 60 miles S.W. of Jodhpore. In the vicinity there are extensive and rich salt marshes, which yield a considerable revenue to the maharaja of Jodhpoor. Coarse cloth is also made here. Pop. 5000.

PUEBLA. See Mexico.

Puebla de Don Fadrique, a town of Spain, in the province of Granada, at the foot of Mount Calar, 77 miles N.E. of Granada. It has a town-hall, several churches and schools, and an hospital. Linen and woollen fabrics are woven here, and there is a considerable trade in timber. Pop. 6555.

Puebla de Montalvan, a town of Spain, in the province of Toledo, in a rich and beautiful country on the Tagus, 17 miles W. of Toledo. It is remarkable for its noble and splendidly-ornamented churches, hospital, and convent. Here is also a palace of the dukes of Uceda. The town has oil and flour mills; and an annual fair is held. Six miles off is the old castle of Montalvan, picturesquely situated in a ravine. Pop. 4332.

PUENTE GENIL, a town of Spain, in the province of Cordova, on the Genil, 27 miles S. of Cordova. Woollen cloth, oil, and earthenware are manufactured here. Pop. 6400.

PUERTO-DE-SANTA-MARIA, commonly called *El Puerto* ("The Port"), a town of Spain, Andalucia, in the province and 7 miles N.E. of Cadiz, near the mouth and on the right bank of the Guadalete, which is crossed by a suspension-bridge. It is a pleasant and well-built though somewhat dull town, in a fertile country; and its houses resemble these of Cadiz, though they are often larger, and profusedly decorated with painting. The principal street, called the Calle Larga, about a mile long, is handsome and well paved, which cannot be said of the other thoroughfares. There are several beautiful public walks shaded with trees; that called La Victoria being the finest. The places of public amusement include a theatre and a ring for bull-fights; the scene of one given in honour of Wellington, and described by Byron. Puerto is chiefly important as a place of exportation of wine. The *bodegas*, or wine stores, are large and lofty buildings, with thick walls and narrow windows; but they are not on such a large scale as those of Xeres. The people are employed to a large extent in farming. So excellent is the water of this place, that most of the drinking-water of Cadiz is conveyed from hence. The harbour of Puerto is formed by the river, but its mouth is obstructed by a dangerous bar. Steamers ply between this port and Cadiz. Timber and iron are the chief imports of the town. Pop. 17,930.

Puerto Cabello, a town of Venezuela, in the province of Carabobo, on a small island connected with the mainland by a bridge, 20 miles N.W. of Valencia. It is well built but unhealthy, has an excellent harbour, and a flourishing commerce. Pop. 7500.

Puerto Llano, a town of Spain, in the province and 20 miles S.S.W. of Ciudad Real. It has manufactures of lace, pottery, flour, &c. Near it there are mineral baths. Pop. 5000.

Puerto Principe, a town of Cuba, capital of a jurisdiction of the same name, stands in the interior of the island, 36 miles W.S.W. of its port, Las Nuevitas, with which it is connected by a railway. It was formerly the seat of the supreme court of justice for the island, but this is now at Havana. A considerable trade is carried on through the port, sugar and tobacco being the chief exports. Pop. of the jurisdiction (1854) 46,532; of the town, 26,648.

PUFFENDORF, Samuel, a distinguished juridical writer and historian, was born in 1632 at Chemnitz, a small town in Saxony, where his father, Elias Puffendorf, was a Lutheran clergyman. He received his elementary education from his father, and studied the humanities at the school of Grimma, theology at Leipsic, and philosophy under Erhard Weigel at Jena. The teaching of Weigel was then exciting considerable attention in Germany, and Puffendorf seems to have eagerly availed himself of his instructions. It was here he seems to have first applied himself to the study of the law of nature on which he was destined to become an eminent writer. Full of the philosophy of Descartes, of the jurisprudence of Grotius, and of the rigorous method of Weigel, he offered his services to his country. His brother Isaac, who was employed by Oxenstierna in lucrative and confidential offices under the government of Sweden, prevailed upon him to seek his fortune in foreign diplomacy; and with that intent he became tutor to the son of the Swedish ambassador at Copenhagen. He had hardly joined the legation when a rupture occurring between the governments of Denmark and Sweden, the embassy was detained as prisoners for eight months in the Danish capital. Puffendorf employed his leisure in reducing to writing, with occasional reflections of his own, the principles of general law contained in the works of Grotius, Hobbes, and other writers of that class. He published this work shortly afterwards, on visiting Holland, with the title of *Elementa Jurisprudentiæ Universalis*, 1660. This crabbed yet original work was dedicated to the elector-palatine Charles Louis, which laid the foundation, perhaps more than the substantial merits of his book would warrant, of the subsequent fortunes of the author. In the university of Heidelberg, which had been gradually falling into decay, Charles Louis founded a professorship of the law of nature and of nations, and chose Puffendorf to fill the chair. He had no sooner opened his course in 1661 than the class-room was crowded with eager listeners to the new professor of law. Flattered by this encouragement, he pursued his juridical studies with unabated zeal; and shortly afterwards published anonymously, at Geneva, *Severini de Mozambano, De Statu Imperii Germanici*. This book exhibited in somewhat strong colours the absurdities and incongruities of that strange compound called the Germanic empire, urging at the same time certain practical remedies for the grievous abuses which had grown up under it. The work created great excitement throughout Europe, and particularly in Austria, where it was put upon the *Index Expurgatorius*, and the executioner was ordered to burn it. Puffendorf defended the work without daring to declare himself the author. The work was printed again and again, and translated into almost all the languages of modern Europe. Meanwhile Puffendorf found his position so uncomfortable that, to avert the possible consequences of the stir, he was glad to accept in 1670, from Charles XI. of Sweden, the chair of the law of nations at the university of Lund, then recently founded. He had hardly occupied his new position two years, when the great work on which his reputation now chiefly rests made its appearance. It bore the title *De Jure Naturæ et Gentium*. It was much more scientifically constructed than the *De Jure Belli et Pacis* of Grotius. Puffendorf, though without the genius or learning of his master, commences with the law of nature, discusses the subject as applied to individuals, and finally investigates the numerous complicated questions which emerge in the intercourse of nations. The new views contained in the work were virulently assailed by some of his contemporaries, and as enthusiastically admired by others, while the tide of his reputation steadily arose until it flooded over Europe. A few years afterwards he removed to Stockholm at the request of the King of Sweden, who appointed him his historiographer, and bestowed upon him the title of Counsellor of State. In this official capacity he published *Commentarii de rebus Suecicis ab expeditione Gustavi Adolphi usque ad abdicationem Christianæ*, Utrecht, 1686. The theme was promising, but Puffendorf was more familiar with the law of nations than he was with the rich details of their history. The work had gained the favour, however, of Frederic William, Elector of Brandenburg; for in 1688 he invited him to Berlin, and, with the consent of the King of Sweden, employed him to write the history of his life and reign. He was again made counsellor of state, and what was more to the purpose, he received an annual pension of 2000 crowns. Accordingly, there appeared in due time *Commentarii de Rebus Gestis Frederici Wilelmi Magni, Electoris Brandenburgici*; and we hope the Elector of Brandenburg received the performance with great enthusiasm, for it has to be recorded that nobody else did. His engagement at Berlin being merely temporary, he purposed returning to Stockholm; but as the King of Sweden had raised him to the dignity of a baron while resident at Berlin, and the climate being less severe in the southern metropolis, Puffendorf preferred postponing his journey northward. He died at Berlin on the 26th October 1694.

Puffendorf's works, which were somewhat voluminous, will be found in a detailed list appended to his Life in the *Biographie Universelle*.

PUGET, Pierre, a celebrated sculptor, architect, painter, and ship-builder, was born at Marseilles on the 31st October 1622. His genius developed itself under very unfavourable circumstances. He had little artistic education and few facilities for artistic study; yet his own innate bias forced him on towards excellence. Every opportunity, however unfavourable, was seized for giving embodiment to those great ideas that began to rise vaguely before his boyish mind. Design in any of its branches, and on any occasion, was ardently practised by the precocious youth. When a mere lad of sixteen, he was superintending the building of a galley in the dockyards of his native city. At the age of eighteen he was gaining a livelihood in Florence by carving in wood. A year had not elapsed before he was found in Rome the favourite pupil of the famous painter Pietro de Cortona. He then returned home at the age of twenty-one, ready to practise in any department of art that might suit his purpose. The established reputation of Puget now secured for him a series of commissions. The building of a most magnificent vessel, named La Reine in honour of Anne of Austria, was entrusted to his superintendence. No sooner had that been completed in 1646 than he was despatched to Rome to make drawings of the most celebrated monuments of antiquity. Six years were spent in this employment, and he then came back to France to undertake the painting of several pictures. His pencil was plied vigorously, until the towns of Marseilles, Aix, Toulon, Cuers, and Ciotat, were embellished with his productions, and his health gave way under the continued toil. Puget, thus compelled to change his vocation, turned his attention to sculpture and architecture. In no long time he began to take a prominent place in the profession. His own native genius, in spite of an imperfect education, led him to discover the secrets of his art. The edifices which he erected at Marseilles and Toulon were remarkable for the boldness, the originality, and the grandeur of their architecture. The statues which he set up at Genoa and other places were unrivalled for their rough vigour and intense expression. Especially did the colossal group of Milo excite the admiration of his contemporaries. While it was still unfinished, intelligence reached the French court about the figure, instinct with the throes of pain and baffled strength, which was gradually coming out from the dull, formless marble in a quiet studio at Toulon. King Louis XIV. issued orders that it should be conveyed to Versailles as soon as it was completed. A chest containing it arrived at the palace in the spring of 1683, and the court gathered round to see it produced. "Ah, poor man!" exclaimed the queen Maria Theresa, as she saw the agonized face of the statue appear. This cry of pity brought the reputation of Puget to a climax. From that time till the time when he died at Marseilles in 1694, he was recognised by his sovereign and countrymen as the greatest sculptor in Europe.

PUGHE, William Owen, an eminent Welsh scholar, was born in the parish of Llanfihangel-y-Pennant in Merionethshire in 1759. All his energies from an early period were devoted to the advancement of his native language. On removing to London at the age of seventeen, he began a series of exertions for preserving and illustrating the ancient Welsh literature. He assisted Owen Jones in editing the poems of Dafydd-ap-Gwilym and of Llywarch Hen, and in compiling the *Myvyrian Archæology of Wales*. At the same time he was producing several works on his own account. His great work, *The Welsh and English Dictionary*, appeared in 1793–1803; and his *Cambrian Biography*, in 1803. Scarcely less indefatigable were his labours in behalf of his mother-tongue, after he had succeeded in 1806 to a considerable estate near Denbigh. He wrote Welsh translations of Milton's *Paradise Lost*, Heber's *Palestine*, and other English poems. He was preparing for the press a treatise on *The Ancient Romances of Britain*, when he died in 1835 at Dolyddy-Cay, a house at the foot of Cader Idris.

PUGIN, Augustus, was an eminent architectural draughtsman who was born in France in 1769, and came over to London to practise his profession. The principal part of his attention was directed to the illustration of the architecture of the middle ages. He published *Specimens of Gothic Architecture selected from various Ancient Edifices in England* in 1821–23; and *Specimens of the Architectural Antiquities of Normandy* in 1825–28. He was also in 1831, the year before his death, assisting his son in producing a work entitled *Gothic Ornaments selected from various Buildings in England and France.*

Pugin, *Augustin Welby Northmore*, the son of the preceding, was born in 1811, and learned the profession of architectural draughtsman under his father. It was not long before he resolved to devote his time to the archæological study of style and symbolism in ornaments. Settling down at Ramsgate in 1833, he carried his resolution into practice both with pen and pencil. *Designs for Gothic Furniture in the style of the Fifteenth Century*, and *Designs for Iron and Brass Work in the Style of the Sixteenth and Seventeenth Centuries*, were published in 1835. *Designs for Gold and Silver Ornaments*, and *Ancient Timber Houses*, were produced in 1836. There followed soon afterwards an arrogant tract entitled *Contrasts, or a Parallel between Ancient and Modern Architecture*. His zeal increased when he had become a member of the Roman Catholic Church. All his energies from that time were devoted to the promotion of that magnificent style of architecture which has been identified with the Popish worship. Numerous churches, chapels, convents, and schools were erected under his superintendence throughout the country to shame the degenerate taste of the age. Especially did he concentrate all his powers upon rearing a model fabric at his own expense at Ramsgate. Nor did he neglect to advocate his views by plain statements. He published *The Principles of Christian or Pointed Architecture*, 1841; *An Apology for the Revival of Christian Architecture*, 1843; *A Glossary of Ecclesiastical Ornament*, 1844; and *A Treatise on Chancel Screens and Rood Lofts*, 1851. In fact, so much and so constantly did the one prevalent idea engage and harass his mind, that his brain became distracted, and he had only been brought back from a lunatic asylum when he died, on the 14th September 1852

PUGNANI, Gaetano, the founder of a celebrated violin-school, was born at Turin in 1727, and became a pupil of Somis, who had studied under Vivaldi and Corelli. Pugnani afterwards took lessons from Tartini, and when twenty-five years old, was appointed first violin of the King of Sardinia's chapel, and director of his concerts. In 1754 he visited Paris, and performed there in public with brilliant success. He was received with great applause in several other European capitals, and remained a considerable time in London, returning to Turin and settling there in 1770. Being made director of the orchestra of the king's theatre, he opened a violin school which sent forth several great artists, the most distinguished of these being the famous Viotti. Besides being a great violinist, possessing a fine tone, a grand and impassioned style, and perfect skill in all the artifices of bowing, Pugnani was remarkable for his talent of conducting an orchestra, a rare talent which he imparted to several of his pupils. He was an excellent composer for stringed instruments, in a bold and original style. Many of his compositions remain in manuscript. One of his nine Violin-Concertos was published at Paris; and there also he published four books of Violin Sonatas, two books of Violin Duets, and three books of Trios for two violins and bass, Paris and London. Six Quartets for two violins, viola, and bass, London. Twelve Symphonies for two violins, viola, bass, two oboes, and two horns, London. Two books of Quintets for two violins, two flutes, and bass, London. He composed the music of nine operas for the theatre. The French invasion of Italy caused him the loss of his offices and income. He died at Turin in 1803. In 1818 the writer of this article saw a portrait of Pugnani in the Gallery of the Liceo at Bologna. The countenance was full of energy and intelligence; but his nose (resembling the exaggerated beak of an eagle), was much too large to be handsome, and gave a ludicrous air of caricature to the portrait. However, Signor Felice

Radicati, violin-master in the Liceo, said that the picture was really a faithful likeness. (G. F. G.)

PULCI, Luigi, a celebrated Italian poet, was born in Florence in 1431. His talents were fostered and developed under very favourable circumstances. A comfortable office in the Florentine republic was held by him. Lucrezia, the mother of Lorenzo de Medici, encouraged him in the cultivation of poetry. Lorenzo himself kept a place for him in that brilliant company who were wont to display the bright coruscations of their wit and genius at his hospitable table. It was under this propitious patronage that Pulci thought of composing an epic poem. Choosing for his subject one of the legends regarding Charlemagne and his paladins, he commenced to treat it on a novel plan. The prevalent custom of narrating the most ridiculous fables with imperturbable gravity, and in pompous mediæval Latin, was repudiated. The ways and manners of ordinary life were introduced into the mysterious regions of romance. He looked upon the marvels there with familiar eye. He described them with the plain colloquial language of Tuscany, and in easy gossiping verse. Nor was his artistic treatment less guided by common sense. Whenever he alighted upon incidents that were natural and impressive, he warmed into earnestness and emotion. Whenever he fell back again upon the absurd exaggerations of the fable, he relapsed into his usual strain of banter and burlesque. The hero Orlando passed across the stage, and was pointed out as the model of a true and chivalrous knight. The villain Gano appeared, and was held up as an object of reprehension and righteous indignation. In this manner the *Morgante Maggiore* (deriving its name from one of its characters, the giant Morgante) was composed, and appeared before the public in 1481. After the author's death, in 1487, it continued to pass through several editions; and its character and merits were for a long time a subject of dispute. It still holds a place among the Italian classics. Luigi Pulci was also the author of a collection of satirical sonnets, and of several other poems.

PULGAR, Fernando del, an eminent Spanish historian, was born at Madrid in the first half of the fifteenth century. Making a fair start, he advanced through life a successful courtier, and a favourite of several successive sovereigns. John II. made him one of his pages. Henry IV. gave him several honourable posts. Isabella brought his preferment to a climax by keeping him near her person as her counsellor, secretary, chronicler, and confidential correspondent. It was in this favourable position that Pulgar set himself to describe the events and men of his time. His annals of the reign of Isabella rose to no great degree of excellence. The former part of this work, ending with the events of 1482, is not trustworthy. The latter part, bringing the narratives down to 1490, abandons the easy, picturesque style of a chronicle, to imitate the ancient histories in their lofty speeches and profound philosophical reflections. Much more able was his other work, *Claros Varones de Castilla*, or lives of forty-six of the most celebrated men of his own age. Catching the spirit of the great classical biographers, he described the knights and gentlemen of Castile with great force and effect. His conception of their characters was earnestly appreciative, his moral reflections were elevated in tone, and his style was dignified and elegant. Pulgar had died about the close of the fifteenth century, before these two productions were published. The *Claros Varones* appeared along with thirty-two of his letters, in 4to, 1500; and the History was first printed in 1565, under the name of Antonio de Lebrija. The best edition of the latter work is that published at Valencia, fol., 1780. One of the best editions of the former is that of Madrid, 4to, 1775. (See Ticknor's *Sp. Lit.*)

PULPIT (Lat. *pulpitum*), is a word which has undergone a great change of meaning. It is now an elevated place in a church in which the preacher stands. Originally it signified that part of the Roman stage on which the actors performed their parts. The French *Pupitre* signifies a reading-desk; while *Chaire* (Καθέδρα) corresponds with the English pulpit.

PULSE, is the alternate contraction and dilatation of the heart and arteries. As the beats of the arteries correspond with the motions of the heart, we can determine from the pulsation of the arteries the state of the circulation, which is highly valuable in many forms of disease. When in a healthy state the pulse beats about 72 times in a minute, or it ranges from 60 to 80 times. It is quicker in women than in men; and it is quicker in the sanguine than in the melancholic temperament, in youth than in age. The pulse of an infant is from 130 to 140; and during the first year it averages from 108 to 120. In feverish complaints it ranges from 100 upwards to 120, 168, and even becomes innumerable. The radial artery is usually chosen for ascertaining the state of the circulation, where it is conveniently seated in the wrist. When this cannot be reached, the temporal artery, at the corner of the lower jaw, may be tried.

PULTENEY, William, Earl of Bath, an eminent politician, was descended from a good family, and was born in 1682. After spending his years of education at Westminster School, and at Christ Church, Oxford, he travelled for some time on the Continent, and on his return was sent to Parliament by Henry Guy, Esq., formerly secretary to the Treasury, as representative of the borough of Hedon in Yorkshire. Guy subsequently left him a legacy of L.40,000, and landed property to the value of L.500 a year. Pulteney had a good estate of his own, and this legacy, together with a large portion brought him by his wife, Anna Maria, daughter of John Gumley, Esq. of Isleworth, enabled him in after life to perform numerous acts of charity and benevolence. On his entry into the House of Commons, he attached himself to the Whig party, and continued to represent Hedon throughout the entire reign of Queen Anne. He made his maiden speech on the "Place Bill;" he distinguished himself on the prosecution of Dr Sacheverell; and, in a word, rendered himself so obnoxious to the Tories, that when they came into power in 1710, they are said to have been avenged on the youthful orator by removing his uncle, John Pulteney, Esq., from the Board of Trade. During the latter years of the Queen's reign he had a principal share in the debates, and in 1712, on the prosecution of Walpole, he defended him in an elegant oration.

When George I. came to the throne, Pulteney was made secretary-at-war, an office which he held till 1717, when Walpole resigned. He was subsequently, in 1720, promoted to the valuable sinecure of cofferer of the household; but in 1725, after a disagreeable quarrel with his friend Sir Robert Walpole, he threw himself into the ranks of the opposition, was dismissed from his office of cofferer, and became so obnoxious to the King, that in 1731 his Majesty called for the council-book, and with his own hand struck out his name from the list of privy-councillors. This proceeding served to inflame his resentment and to increase his popularity; and he continued his attacks upon Walpole with a severity of eloquence and sarcasm which nothing could withstand. Nor did he confine his opposition to his speeches in Parliament: out of doors he assisted Bolingbroke in his paper called the *Craftsman*, and in numerous pamphlets he held up the minister and his friends to the scorn and reprobation of the nation. His shining qualities as a debater, the hot patriotism with which he spiced his harangues as leader of the opposition, lifted him to the height of public esteem, and rendered him the most popular man in the country. Meanwhile Walpole was at last overthrown, February 1742, and the entire authority seemed for a moment to lie at the feet of Pulteney. But Walpole secretly influenced his Majesty in his negotiations with his rival; the composition of the new cabinet disappointed the expectations both of his immediate partisans and of the public; suspicion and a sense of injury done to the cause burst into a perfect storm of popular indignation; when Pulteney, under cover of the smoke thus raised, walked into the House of Lords as Earl of Bath—shrunk, in short, as Chesterfield phrased it, "into insignificance and an earldom." In February 1746, on the resignation of the Pelham ministry, he held the premiership for two days, but was constrained to retire, as no persons of weight would join him. In 1760 he published *A Letter to Two Great Men* (Pitt and the Duke of Newcastle), recommending proper articles to be insisted on in a treaty of peace. It was published anonymously, was greatly applauded, and went through several impressions. He died in 1764; and as his only son had died before him, the title became extinct.

PULTUSK, a town of European Russia, in the kingdom of Poland and government of Plock, on the Narew, 32 miles N.N.E. of Warsaw. It has an episcopal palace, cathedral, and other churches; a nunnery, school, and hospital. Brandy is made, and an active trade carried on here. At Pultusk, in 1703, Charles XII. gained a victory over the Saxons and Poles; and in 1806 a battle was fought between Napoleon and the Russians, in which the former had the advantage, though both sides claimed the victory. Pop. (1854) 4772.

PUMP. See HYDRODYNAMICS, part iii., c. iii.

PUMPKIN. See BOTANY, c. iii., Nat. Ord. *Cucurbitaceæ.*

PUN is defined by Addison, in a paper in which he traces the history of punning from its original to its downfall (*Spectator*, No. 61), as "a conceit arising from the use of two words that agree in the sound but differ in the sense." To render this definition less objectionable, it may be varied into,—a conceit produced by the novelty and unexpectedness arising from the use of two words that agree in the sound, but differ in the sense, or of one word used with a double application. Addison observes, in the paper just mentioned, that "Aristotle, in the eleventh chapter of his *Rhetoric*, describes two or three kinds of puns, which he calls paragrams, among the beauties of good writing, and produces instances of them out of some of the greatest authors in the Greek tongue." "Cicero," he goes on to observe, 'has sprinkled several of his works with puns; and in his book, where he lays down the rules of oratory, quotes abundance of sayings, as pieces of wit, which also, upon examination, prove arrant puns." The age in which this species of wit chiefly flourished was in the reign of King James I. His majesty was a tolerable punster, and the taste of the sovereign was studied by the courtiers and by the clergy. The greatest authors, in their most serious works, made frequent use of puns. The sinner was punned into repentance, and in the theatres tears were solicited and got at no higher price. Quintilian and Longinus seem to have been the first among the ancients to distinguish between puns and true wit.

The writer of a clever paper in the *Guardian*, No. 36, named Birch, in "A Modest Apology for Punning," draws the distinction between the extemporaneous puns of conversation, and the deliberate and grave use of this species of false wit in general composition. While defending the pun as a means of enlivening the dull wits of those engaged in common conversation, he nevertheless affirms, "I look upon premeditated quibbles and puns committed to the press as unpardonable crimes. There is as much difference betwixt these and the starts in common discourse, as betwixt casual rencounters and murder with malice prepense."

PUNCH, a principal character in a well-known puppet-show, seems to be a corruption of the Italian *Policinella*, who is usually the leading character in Neapolitan puppet-shows. According to Galiani, in his *Vocabolario del Dialetto Napoletano*, Policinella, or Polecenella, was the name assumed by the successors of a facetious vintager with a very large nose and grotesque appearance, named Puccio d'Aniello, who, taking to the stage, crowded the theatres with his antic tricks and farcical drollery. By degrees, personifications of the original Polecenella were multiplied all over the country. On being transported into Britain, the name became Pochinella, and Punchinella, and, for shortness, *Punch*. Hence the name also of that popular publication the *London Charivari*.

PUNCTUATION, in grammar, the art of pointing, or of dividing a discourse into periods, by points expressing the pauses to be made therein.

The points used in English composition are as follows:—The *comma*, marked thus (,); the *semicolon*, marked thus (;); the *colon*, marked thus (:); the *period*, marked thus (.); the *interrogation*, marked thus (?); the *admiration*, marked thus (!); to which may be added the *dash* (—), the *apostrophe* ('), and the *parenthesis* ( ). We shall only observe, in general, that the comma is used to distinguish nouns from nouns, verbs from verbs, and such other parts of a period as are not necessarily joined together. The semicolon serves to suspend and sustain the period when too long; the colon to add some new or supernumerary reason or consequence to what is already said; and the period to close up the sense and construction, and release the voice.

It has been asserted that punctuation is a modern art, and that the ancients were entirely unacquainted with the use of our commas and other points, and wrote not only without any distinction of numbers and periods, but also without distinction of words; a custom which, Lipsius observes, continued until the hundred and fourth Olympiad, during which time the sense alone divided the discourse. What places this beyond dispute is the Alexandrian manuscript, in the British Museum. Whoever examines this codex, will find that the whole is written *continuo ductu*, without distinction of words or sentences. How the ancients read their works written in this manner it is not easy to conceive. After the practice ceased of joining words together, notes of distinction were placed at the end of every word. In all the editions of the *Fasti Capitolini* these points occur. The same are to be seen on the *Columna Rostrata*. For want of them, we find much confusion in the *Chronicon Marmoreum*, and the covenant between the Smyrnæans and Magnesians, which are both at Oxford. In Salmasius's edition of *Dedicatio Statuæ Rigillæ Herodis* the same confusion occurs, where we find ΔEYPITE and Δευρ ιτε.

Of these marks of distinction, the Walcote inscription found near Bath may serve as a specimen:—

IVLIUSv VITALISv FABRI
CESISv LEGv XXVv Vv V
STIPENDIORUMv

After every word here, except at the end of a line, we see the mark v. There is an inscription in Montfaucon, which has a capital letter laid in an horizontal position, by way of interstitial mark, which makes one apt to think that this way of pointing was sometimes according to the fancy of the graver:—

P. FERRARIVS HERMES
CAECINIAE ⊢ DIGNAE
CONIVGI ⊢ KARISSIMAE
NVMERIAE ⊢

Here we observe after the words a T laid horizontally, but not after each word, which proves this to be of a much later age than the former. As the improvement of stops appears not to have taken place whilst manuscripts and monumental inscriptions were the only known methods of conveying knowledge, it is conjectured that it was introduced with the art of printing. The fourteenth century, to which we are supposed to be indebted for this invention, did not, however, bestow those appendages which we call *stops.* Whoever will be at the pains of examining the first printed books will discover no stops of any kind, but arbitrary marks here and there, according to the humour of the printer. In the sixteenth century we observe their first appearance. From the books of this age, we find that they were not at all produced at the same time; those we meet with in use being only the comma, the parenthesis, the interrogation, and the full point. To prove this, we need but look into Bale's *Acts of English Worthies,* in black letter, printed in 1550. In the dedication of this book to Edward VI. we discover a colon, it is true; but as this is the only one of the kind throughout the work, it is plain that the colon was not established at that time, or, if it was, that it had not yet come into common use. Thirty years afterwards, in the sensible and judicial performance of Sir Thomas Elyot, entitled *The Governour,* imprinted in the year 1580, we see the colon as frequently introduced as any other stop; but the semicolon and the mark of admiration were still wanting, neither of these being visible in Sir Thomas's book. In Hackluyt's *Voyages,* printed in 1599, we meet with the semicolon; but, as if the editors did not fully apprehend the propriety of its general admission, it is sparingly introduced. It has been said, indeed, that the semicolon was brought into use at a much earlier period; but it appears that it was only for the purpose of an abbreviation, as in (*namq;*) (*neq;*) for *namque, neque,* and not in the sense in which it is now employed.

The semicolon, as well as all the ordinary points, is used in a work entitled *Imagines Deorum,* printed at Leyden in the year 1581, in Roman characters. We likewise meet with them in the translation of a book written in French by Philip de Mornay, lord of Plessis; in the *Schoolmaster* of Roger Ascham, printed in 1570, with the exception of the semicolon; and in the *Trewnesse of the Christian Religion,* by Sir Philip Sidney, published in 1587, in which we find the asterisk, brackets, the interrogation, the comma, and the semicolon, all as we now use them, the colon and period being square dots. In an alchemical manuscript, of date 1572, the semicolon is said to be met with, as well as the other three points which are now in common use. The colon and period are abundant in a work entitled *Dionysius de Situ Orbis,* printed at Venice in 1498, but none of the other stops or points occur. The single point (·), appears to be the most ancient. Since the year 1485 the colon was introduced; the comma is first seen about the year 1521; and the more refined semicolon was brought into use about the year 1570. The invention of the semicolon is most probably due to the English; for, from the Leyden edition of Pliny, 1553, it is evident that the Dutch printers were not then in the practice of using it; and if they were in 1570, Roger Ascham would probably have employed it, since the Dutch were the principal classical printers in his time. But we find that some English books were marked with it at that period. The note of admiration was the last stop invented, and seems to have been added to the rest at a period not very far distant from our own time.

Thus we see that these notes of distinction came into use as learning gradually advanced and improved; one invention, indeed, but enlarged by several additions. But notwithstanding what has been said relative to the use of stops as being a modern invention, we shall find reason to be satisfied that the ancients were not unacquainted with the method of making pauses in speaking and writing, if we attend to the following investigation of Warburton:—

"Some species of pauses and divisions of sentences in speaking and writing must have been coeval with the knowledge of communicating ideas by sound or by symbols. Suidas says that the *period* and the *colon* were discovered and explained by Thrasymachus about 380 years before the Christian era. Cicero says that Thrasymachus was the first who studied oratorical numbers, which entirely consisted in the artificial structure of periods and colons. It appears from a passage in Aristotle that punctuation was known in his time. The learned Dr Edward Bernard refers the knowledge of pointing to the time of that philosopher, and says that it consisted in the different positions of one single point. At the bottom of a letter, thus (A.), it was equivalent to a comma; in the middle (A·) it was equal to a colon; at the top (A˙) it denoted a period, or the conclusion of a sentence. This mode was easily practised in Greek manuscripts, while they were written in capitals. But when the small letters were adopted, that is, about the ninth century, this distinction could not be observed; a change was therefore made in the scheme of punctuation. According to Cicero, the ancient Romans as well as the Greeks made use of points. He mentions these under the appellation of *librariorum notæ;* and in several parts of his works he speaks of '*interpunctæ clausulæ in orationibus.*' Seneca, who died A.D. 65, expressly says that Latin writers in his time had been used to punctuation. '*Nos, cum scribimus, interpungere consuevimus.*' Muretus and Lipsius imagined that these words alluded to the insertion of a point after each word; but they certainly were mistaken, for they must necessarily refer to marks of punctuation in the division of sentences, because in the passage in which these words occur, Seneca is speaking of one Q. Haterius, who made no pauses in his orations. According to Suetonius, Valerius Probus procured copies of many old books, and employed himself in correcting, pointing, and illustrating them; devoting his time to this and no other part of grammar. It appears from hence that, in the time of Probus, or about the year 68, Latin manuscripts had not been usually pointed, and that grammarians made it their business to supply this deficiency. Quintilian, who wrote his celebrated treatise on Oratory about the year 88, speaks of commas, colons, and periods; but it must be observed that by these terms he means clauses, members, and complete sentences, and not the marks of punctuation. Ælius Donatus published a treatise on Grammar in the fourth century, in which he explains the *distinctio,* the *media distinctio,* and the *subdistinctio;* that is, the use of a single point in the various positions already mentioned. Jerome, who had been the pupil of Donatus, in his Latin version of the Scriptures, made use of certain distinctions or divisions, which he calls *cola* and *commata.* It has, however, been thought probable that these divisions were not made by the addition of any points or stops, but were formed by writing, in one line, as many words as constituted a clause, equivalent to what we distinguish by a comma or a colon. These divisions were called στίχοι or ῥήματα, and had the appearance of short irregular verses in poetry. There are some Greek manuscripts still extant which are written in this manner."

PUNDERPOOR, a town of British India, in the presidency of Bombay and province of Sattara, stands on the Beema, an affluent of the Kistna, 112 miles S.E. of Poona, and 185 S.E. of Bombay. It is well and regularly built, containing several palaces, and a celebrated temple of Vishnu, which is an object of great reverence to the Brahmins. There is here a large market, which is well supplied with the produce of the country and with British goods. Pop. about 20,000.

PUNISHMENTS. See LAW, and PRISONS.

PUNJÁB.

Extent and boundaries.

The Punjab, or more properly *Panjáb*, so called from the Persian words, *panj*, "five," *áb*, "water," in allusion to the five rivers, the Jílam[1] or *Hydaspes*, the Chenáb or *Acesines*, the Raví or *Hydraotes*, the Beah or *Hyphasis*, and the Satlej or *Hysudrus*, which water it, is bounded on the W. by the Sulaimán Mountains and that part of Afghánistán which adjoins the Khaibar Pass, on the N. by the dominions of the Rájá of Jamú, on the E. by the Himálya Mountains, and on the S. by the Satlej. According to this limitation, the Panjáb does not coincide with the dominions of Ranjít Singh; the Jamú territory and Kashmír having been formed into an independent kingdom under Guláb Singh in March 1849, when the main portions of the Panjáb were annexed to the British empire. It is further to be observed that the portions then annexed are called the Panjáb proper, in contradistinction to two provinces, the Jalandar Doáb, or Trans-Satlej states, with the adjoining hill district of Kángra, and the Cis-Satlej states which had been annexed previously. The Cis-Satlej states not properly belonging to the Panjáb, are excluded altogether from consideration here.

The *Jalandar Doáb* is the rich tract lying between the Beah and the Satlej, or between N. Lat. 30. 57. and 32. 5., E. Long. 75. 4. and 76. 38. It contains an area of 374 square miles; and Jalandar, the chief town, has a population of 40,000.

The *Kángra Valley*,[2] divided into three portions,—the western or Rihu valley; the middle or Kángra valley, properly so called; and the eastern or Páhlam valley, is about 60 miles long, and averages 10 in breadth. These valleys are surrounded by hills. The complete area of the Kángra district, including both hills and valleys, has not been accurately ascertained.

The *Panjáb proper* extends from the 34th to the 29th degree of N. Lat., 344 miles in its greatest length, and from the 70th to the 75th meridian of E. Long., 293 miles in its greatest breadth. Its area is about 66,700 square miles. It is of a triangular shape, the apex being to the south, where the Panj-nad unites with the Indus. It is divided into four *doábs* or valleys, interjacent between two rivers. These doábs are—1. The Barí,[3] between the Beah and Raví; 2. The Rechnah, between the Raví and the Chenáb; 3. The Chaj, between the Chenáb and the Jílam; and 4. The Sindh Ságar, between the Jílam and the Indus. Besides these doábs, the *Hazára* country and the Trans-Indus frontier must likewise be included in the Panjáb proper. The Hazára country has an area of 2500 square miles. It constitutes the extreme north-west angle of the Sindh Ságar Doáb. It consists of a series of valleys encircled by hills, the most remarkable of which are the Dond and Satí, on a spur of which latter range the sanatarium of Marrí (*Murree*) was built in 1852, at the height of 7330 feet above the sea. In this delicious climate every kind of European and tropical fruit may be successfully cultivated. The station is fast becoming populous, and houses are rising in every direction. North-west of Hazára, and separated from it by the Indus, is the province of Peshávar, divided into the Yúsufzye country, Hashtnagar, the Doába, and Peshávar proper; the total area being about 2400 square miles. Yúsufzye is bounded on the south by the Indus, north and east by the Swát Mountains, and west by the Kábul River, and the Mehra, or desert, between it and Hashtnagar. Hashtnagar, or "Eight Cities," is a narrow but fertile tract on the Swát River, and has its name from eight large villages in that locality, of which the chief is Tungí. Doába is inclosed by the Swát and Kábul rivers. Peshávar proper is divided into two districts,—one on the right bank of the Kábul River, and adjoining the Khatak and Afrídí Hills, which run down to a point at Atak; the other of a triangular shape, the base being the Khaibar Hills, and the two sides the Kábul River and the Bara, one of its tributaries. South of Peshávar is Kohat, a valley 30 miles long, and on an average 4 miles broad. Its other boundaries are the Bannu valley to the south, the Wazírí and Bangash country to the west, and the ridges which overhang the Indus to the east, which are inhabited by the Khataks, a valiant Afghán tribe. The Kohat valley is continued by the valley of Hangu, 20 miles long by 3 broad, which opens into the plains of Míránzye. This plain is 9 miles square, and is bounded on the south-west by the Khuram River, 20 miles from where it emerges into the Bannu plain.

South of Kohat is the valley of Bannu, which is rich, fertile, and well irrigated. The capital is Dhalípgarh, where there is a substantial fort with a cantonment. Still more to the south are the valley of Marwat, and the adjoining valley of 'Isa Khail, containing 45 villages. The Tánk valley comes next, and in fertility equals Bannu. South-east of Tánk is Derah Ism'aíl Khán; 60 miles south of this, Derah Fath Khán; and 70 miles farther in the same direction, Derah Ghází Khán; all three formerly the camps of powerful Afghán chiefs who three centuries ago invaded the Panjáb. After passing Derah Ghází Khán, the country of the Bílúchís is reached. Of these, there are the Ushtaránís, the Bozdárs, the Laghárís, Bugtís, Marís, and Ghurchánís, all valiant and refractory tribes.

The total area of the Panjáb, and the allied state of Jamu, is about 126,000 square miles.

General aspect of the country.

The Panjáb is a country of extensive plains, but little above the level of the sea, bounded on the N. and N.E. by hills which unite with the spurs of the gigantic Himálya Mountains. The slope of the whole region is from N.E. to S.W., as is shown by the uniform course of the rivers. Jacquemont[4] argues, from barometric and other observations, that the plain of the Panjáb is lower than that of Eastern Hindústán, and supposes that the beds of the rivers from the Jamná to the Indus are successively lower than one another.

According to Elphinstone[5] the fertility of the Panjáb has been exaggerated; and, except near rivers, no part is comparable to the British provinces in Hindústán or Upper India, far less with Bengal. Of the four doábs east of the Jílam, the two nearest that river are chiefly pasture grounds; the third, though most sterile, is best cultivated. The two former are flat, the latter undulating. To the east of the Jílam there is scarce a hill or a tree except the mimosa.

According to the General Report,[6] "the face of the country presents every variety, from the most luxuriant cultivation to the most sandy deserts, and the wildest prairies of grass and brushwood. A traveller, passing through those lines of communication which traverse the northern tracts, would imagine the Panjáb to be the garden of India; again, returning to the road which intersects the central tracts, he would suppose it to be a country not worth annexing. The culture manifestly depends upon two causes—the lower Himályan range and the rivers. From the base of the hills southward there stretches a strip of country from 50 to 80 miles broad, watered by mountain rivulets, and for fertility and agriculture unsurpassed in Northern India. In their downward course the rivers spread wealth and fruitfulness on either side, and their banks are enriched with alluvial deposits, and fringed with the finest cultivation. These tracts, though unadorned with trees, and unrelieved by any picturesque features, are studded with well-peopled villages, are twice a year covered with waving harvests, and are the homes of a sturdy, industrious, and skilful peasantry. Within this tract are situated the sister capitals of Láhor and Amritsir, and most of the chief cities, such as Dínanagar, Battála, Siyálkot, Wazírábád, Gujaránwálá, Rámnagar, and Gujarát. Far different is the scene which meets the eye in the centre of the Barí, the Rechnah, and the Chaj Doábs. Here are interminable wastes, overgrown with grass and bushes, scantily threaded by sheep-walks and the footprints of cattle. These parts are chiefly tenanted by nomad pastoral tribes, who, knowing neither law nor property, collect herds of cattle, stolen from the agricultural districts. Here and there a hamlet stands alone in the wilderness, whose semi-barbarous inhabitants are the aborigines of the land." Around the homesteads are patches of good cultivation, for the soil repays irrigation, though water must be raised from a considerable depth. But there are many proofs that these regions were once thickly populated. Everywhere are the ruins of cities, villages, temples, tanks, and water-courses. Even now these tracts are not without their practical value. They yield an abundant supply of grass, on which vast herds of cattle and buffaloes, and flocks of sheep and goats, are pastured, and firewood is collected from them sufficient for the requirements of all the neighbouring towns and villages. Camels, too, in great numbers, are fed in these plains, and form the carriage for the traffic with Kábul and the rest of Afghánistán. The Sindh Ságar Doáb is far less productive, being in fact little better than a sandy desert, within which the famous fort of Mankhera is the only spot where men seem to have a fixed abode.

---

[1] M'Gregor's *History of the Sikhs*, p. 1. If the Indus be included in the five rivers, the Beah and Satlej must be reckoned as one, which in fact they become in Lat. 31. 11., Long. 75. 4. It is certain, however, that the Indus is not reckoned one of the five rivers by the natives, as the united rivers mentioned in the text, before their confluence with the Indus, are called *Panjnad*, which is equivalent to the Persian *Panjáb*.

[2] *Selections from the Public Correspondence for the Affairs of the Panjáb*, vol. i., p. 293 (Dr Jameson's Report).

[3] It will be seen that the names of three of these Doábs are composed of consonants taken from the names of the rivers that form their limits; thus, Barí takes *B* from Beah, and *R* from Raví.

The Salt Range.

But the want of vegetable products in this doáb is more than made up by its richness in minerals. The line of mountains called the Salt Range present an inexhaustible supply of salt, which, at its western extremity, near Kálábágh, is thus described by Elphinstone:[1]—"The road beyond was cut out of the solid salt at the foot of cliffs of that mineral, in some places more than 100 feet high above the river. The salt is hard, clear, and almost pure. It would be like crystal, were it not in some parts streaked and tinged with red. In some places salt springs issue from the foot of the rocks, and leave the ground covered with a crust of the most brilliant whiteness. All the earth, particularly near the town, is almost blood-red; and this, with the strange and beautiful spectacle of the salt rocks, and the Indus flowing in a deep and clear stream through lofty mountains past this extraordinary town, presented such a scene of wonder as is seldom to be witnessed." The Cis-Indus salt mines, seven in number, have long been known, and are mentioned in the Ayín i Akbarí.[2] Burnes[3] states that in 1832 the quantity of salt dug out was 80,000,000 lb. The salt is either found cropping out in all directions, or else lies in strata, commencing near the surface, and extending downwards in deep veins of inexhaustible fecundity. The salt is brought to the mouth of the mine for less than 2 ánás (3d.) a *man* of 80 lb., but is sold at the government depôts at 2 ánás. The mines now worked are five,—Khewra, near Pind Dádan Khân (which is the principal one), Makrách, Sardí, Chuá Varchá, and Kárábágh. The total yield for 1851 was 51,249,440 lb.; for 1855–6, 77,268,800 lb., yielding a revenue of L.193,000. In 1857–58 the revenue from the salt mines was L.207,500. The mineral in all its varieties is a nearly pure chloride of sodium with a trace of sulphate of lime.[4] For consumption it requires no preparatory process, except pounding. It is of excellent flavour and purity, of transparent brilliance and solid consistency; but it assumes a reddish hue,[5] when, as is sometimes the case, veins of iron lie adjacent to the strata. The Trans-Indus salt has a darker tinge than the Cis-Indus, and is generally of inferior quality. Some useful works have lately been executed to facilitate the mining operations. Roads have been cut, and a gallery carried through the heart of the mountain to the Longewala, the chief of the Khewra mines. Fresh water has also been brought to the mines by a canal, as the miners suffered greatly from the use of brackish water in former years.

Mountains.

The mountains in the Panjáb increase gradually in height as they approach the Himálya. In Kángra, for example, the greatest altitudes are between 3000 and 4000 feet. Thus, Barwánah, about 20 miles E. of Kángra, is 3198 feet high; Baijnàth, 15 miles E. of Barwánah, 3357; and about 30 miles E. of this, again, are the snowy peaks, of which the nearest are 14,886, and the more remote 16,017 feet high. Beyond these, again, are the Great Himálya, rising to from 20,000 to 25,000 feet.

In the Rájá of Jamu's country, in N. Lat. 33. 20., E. Long. 73. 50., is the isolated peak of Chan Mukh, 4461 feet high. Not very far to the N. the barrier-line of mountains on the S. of Kashmír is more than double this altitude. Thus, Tikhear peak, in this range, is 15,305 feet; the Barina Sákal is 15,483 feet; the Kohnárdwa, 12,746 feet; and the Didgun Mountain is 14,952 feet. In the N.W. angle of the Panjáb, where the province joins the Afghân hills, the heights range from 4000 to 8000.

Rivers and canals.

The Panjáb is a land of many rivers. Of these, the most eastern, the Satlej, has its source in Thibet, in N. Lat. 30. 8., E. Long. 81. 53., and after a course of 550 miles, receives the Beah near Harekí, in Lat. 31. 12., Long. 75. 3., whence the united stream of the two rivers is called Ghárá, until it joins the Chenáb, after which it bears the name of Panjnad to its confluence with the Indus, a distance of 60 miles. The Beah, which comes next, following the order from S.E. to N.W., rises in Lat. 32. 24., Long. 77. 12., and joins the Satlej after a winding course of 290 miles. The next stream in the same direction is the Raví, which rises in a lake in the Himályas, in Lat. 32. 30., Long. 77. 1., and after a tortuous course of 420 miles, runs into the Chenáb. The Chenáb rises in Lat. 32. 48., Long. 77. 27., and after a course of 600 miles unites with the Jílam at Trimu Ghát. From this point it is called the Trimáb. It receives the Raví after a further course of 50 miles, and after 110 miles more the Ghárá. Hence to the Indus it is called the Panjnad or "Five Rivers," being the united streams of the Beah, the Satlej, the Raví, the Chenáb, and the Jílam. The Jílam rises in Kashmír, and, as above mentioned, joins the Chenáb after a course of 490 miles. The Indus, which is properly the boundary of the Panjáb to the W., washes the confines of the province for 500 miles, in a course nearly due S. from Darband to its confluence with the Panjnad, a few miles N. of Mithankot.

The canals in the Panjáb are classed under two heads,—Inundation canals, which are full during the latter part of spring,[1] the summer and autumn, and empty during the winter. The fertility of the province, particularly of the S.W. portion, depends greatly on these canals, which, though individually insignificant, are in the aggregate of great importance. Permanent canals are full all the year round, and are adapted for navigation as well as irrigation. Of these, the principal is the Barí Doáb Canal, running from N. to S. right down the centre of the tract between the Raví and Satlej. It leaves the Beah exactly in Lat. 32., about 9 miles E. and by S. of Ghordáspúr, and passing 3 miles to the E. of Amritsir, enters the Raví in 30. 32. between Chichawatrú and Burjí. This is called the main branch, and is 265 miles long. It throws off 28 miles S. of the place, when it leaves the Beah, a branch to the W. called the Láhor branch. This will be 74 miles long, and of this distance 60 miles have been excavated. There are to be two eastern branches, one of which, called the Kassúr branch, is to be 84 miles long, and of this about 30 miles are finished; the other is an offshoot of the Kassúr branch, and when finished will be 61 miles long. At intervals of 2½ miles above Láhor, and of 4 miles below that latitude, there will be bridges, in all 115. The main channel is 120 feet broad, and 8½ deep. After the divergence of the Kassúr branch it is 85 feet broad, with the same depth; and after the Láhor branch leaves it, 68 feet wide and 4½ deep. The last report on the administration of the Panjáb speaks of only 133 miles of the main branch being opened by the present year, down to the tail of the Láhor branch. It adds that the canal is eventually to be carried to Tolamba, near Multán. In connection with the canal, 500 miles of road have been completed, and 440,000 trees have been planted along its banks. Permanent workshops are in course of erection at Mádhupúr, the canal head station. The total cost of this grand canal is estimated at L.1,350,000 sterling. The Haslí Canal was made in 1633 A.D. by command of Sháh Jahán, to supply the royal gardens near Láhor. When the Sikhs rose to power they carried a branch from it to Amritsir. It has a winding course of 110 miles, and is from 50 to 15 feet broad, from 7 to 2 feet deep. In the Pák Patan district of the Barí Doáb is the Khánwa Canal, 54 miles long. The canals in the Multán districts are particularly numerous.

[5] *Report on the Panjáb*, p. 76.

Roads. Up to May 1854 roads to the extent of 5229 miles had been constructed, at a cost of L.545,000. Since that time very great progress has been made. The Panjáb section of the grand trunk road from Calcutta to Peshâwar is the most important. This would probably have been nearly finished ere this, but owing to the mutinies and the expenses they entailed, no progress worth mentioning has been made during the last two years. The portion from Firúzpúr to Láhor, 45 miles, is still unfinished. Much remains to be done on the part from Láhor to Peshâwar; and, according to the estimates, L.535,000[2] are required to complete the works, and the whole road will then have cost 1¼ million. Along this road the main forces of the Panjáb army are massed; and its military and commercial importance cannot be exaggerated. Minor roads have been made in many directions; and since May 1854 the extent of new-made roads amounts to 3542 miles.

Railroads. The first sod of the intended railway between Láhor and Amritsir, a distance of 35 miles, was turned by Sir J. Lawrence on the 8th of February 1859. Amritsir is the northern terminus of the Multán and Láhor Railway, which will join or cross the Great North-Western line between Calcutta and Peshâwar. From Multán to Karáchí, the port of the Indus in Sindh, 425 miles, the communication will be continued in the first instance by steamers to Haidarábád, the capital of Sindh, 302 miles, and thence by rail to Karáchí. Ultimately the railway will be continued from Multán to Haidarábád. By this line the whole commerce of the Indus valley will be drained. In a military and political view, the line between Láhor and Peshâwar, as yet uncommenced, is of hardly less importance.

Climate. The climate of the Panjáb is very trying to European constitutions. In the northern parts the fall of rain[3] exceeds that at Delhi, but towards Multán there is hardly any at all, and in the central districts the rain is scanty. The average fall for the whole province was in 1853-54 only 39·38 inches; in 1854-55, 23·84; and in 1855-56, 15·18 inches. The general character of the climate may indeed be inferred from a well-known oriental couplet, often quoted by natives:—

> "Dust, beggars, dog-days, dead men's graves—these four
> Blessings, are the greetings of Láhor."

The months from October to March are pleasant; but during the rest of the year the heat is inconvenient, and at times almost insupportable. The thermometer then rises to 112° in a tent, with all cooling appliances. In the winter months, viz., December, January, February, the thermometer is some nights as low as 34°. In the northern and hilly parts it occasionally falls several degrees below the freezing-point. Fevers and ague are very common in the Panjáb, and may decidedly be attributed to the climate, the intense heat rendering the body susceptible of such complaints.

Zoology. The beasts of prey ordinarily found in India are to be met with in the Panjáb. Tigers are not uncommon. The lion, which was some years back occasionally seen, is now extinct. Panthers, chítás, bears, and hyænas, are by no means scarce; and lynxes, foxes, jackals, otters, martins, storks, nílgáes, wild hogs, porcupines, deer, and monkeys are found, as in India; but wolves are very numerous, and in some years have committed great ravages, even entering the villages and carrying off the children. Of birds there are many varieties, particularly of water-fowl, such as pelicans, cranes, herons, and ducks; eagles, vultures, hawks, pheasants, jungle-fowl, pea-fowl, parrots, partridges, quails, snipe, magpies, hoopooes, pigeons, doves, the bulbul, kokil or Indian cuckoo, and bats are also seen in great numbers. Alligators and the sharp-snouted porpoise of the Indus are plentiful in the rivers, which abound with fish, particularly with the *palla*, which in flavour somewhat resembles the salmon. Snakes are rather common, and some kinds, as the cobra, are deadly. The silk-worm thrives; and the bees produce honey of the finest quality. Amongst domestic animals, the horse is very much cared for, and the breed is fine. Great herds of buffaloes are fed on the rivers' banks; and the camel seems to find the country and climate congenial.

Natural produce. About one-fourth of the whole area of the plains is under cultivation, but the cultivated land is now continually increasing. The crops are much dependent upon rain; and, besides, in most places constant irrigation from wells or canals is requisite. The great staples are cereals, three-fourths of the produce consisting of wheat, barley,[4] Indian corn and maize of all sorts, and rice. In various districts sugar of excellent quality, *gram* (*Cicer arietinum*), cotton, indigo, linseed, turnips, pepper, tobacco, turmeric, poppy, hemp, and vegetables are largely grown, and one or other of these crops in detailed patches is to be found everywhere. All these miscellaneous products, however, united, do not cover more than one-fourth of the cultivated area, the rest being occupied by cereals. There is vast pasturage; and enormous numbers of sheep, goats, camels, and horned cattle are supported on it. Wheat is exported to the Mauritius; and upwards of 5000 tons of produce are annually carried from the Panjáb down the Indus, consisting of cereals, indigo, sugar, cotton, flax.[1]

[3] Elphinstone's *Account of Kábul*, i. 130.

[4] *General Report from* 1854-55 to 1855-56, p. 22.

In the Kángra valley, at Nagrota and at Bowarnah, in the eastern portion of the valley, are tea plantations, and excellent Pouchong, Souchong, and Bohea are made there. At Holta, in N. Lat. 32. and E. Long. 76. 30., also in Kángra, another plantation has been formed. The height of the tract above the sea is from 3500 to 4000 feet, and the teas at this height are said to be very highly flavoured.

The cultivators of the Panjáb are essentially peasant proprietors. There are no farmers or middle-men, and generally no great landlords. As a rule, each man owns and tills his own glebe, upon which he pays the revenue and pockets all the profits. In the Panjáb one and the same man is usually absolute proprietor, and generally the sole cultivator, though he may occasionally lease out a few fields to tenants. He is saddled with no rents. He has to provide for the cost of cultivation and for the government demand; and the rest of the produce is his own. But these men, while maintaining their individuality, do yet belong to village communities. A village is not inhabited by a certain number of peasants, unconnected with each other, but by a number of persons of common descent, forming one large brotherhood, having their own headmen, accustomed to joint action and mutual support.

Territorial divisions.

The Panjáb beyond the Beah is divided for administrative purposes into five provinces. Between the Beah and the Satlej are the Trans-Satlej states, which may be viewed as one large province with five divisions. The whole country may be classed therefore under the following heads, the order being from S.E. to N.W. :—

Divisions.	Area in Square Miles.	Revenue.	Population.	Pop. per Sq. Mile.
		L.		
TRANS-SATLEJ STATES.				
1. Kángra......... 2. Hushyárpúr ... 3. Phagwára....... 4. Jalandar........ 5. Kapurthala	6,791·83	339,129	2,273,037	334·67
PANJAB PROPER.				
1. Láhor	11,627·88	431,711	3,458,694	297·41
2. Multán............	15,494·00	237,730	971,175	62·68
3. Leia...............	15,271·70	169,666	1,122,621	73·50
4. Jílam	16,761·22	237,730	1,762,488	105·35
5. Peshávar.........	7,588·50	95,164	847,695	111·70
NATIVE STATES.				
1. Trans - Satlej principalities	5,316·00	81,828	498,163	54·68
2. Mahá Rájá Rambír Singh's territories	60,000·00	800,000	3,000,000	50·00
Total.......	138,851·13	2,402,958	16,933,873	136·24625

From this calculation the Cis-Satlej states and principalities, and Bháwalpúr, and the hill states near Simla, are excluded. They are given in the Panjáb Reports; but not properly belonging to that country, are here omitted.

The following table gives the income and expenditure for the three years from 1855 to 1858 of the Panjáb territories, including the Cis- and Trans-Satlej states :—

	1855–6.	1856–7.	1857–8.
Income..................	L.2,012,693	L.2,037,779	L.2,053,071
Expenditure..........	1,632,974	1,650,007	1,766,676
Surplus..........	L.379,719	L.387,772	L.286,395

The various sections of the income and expenditure for the last of these years were as follows :—

Revenue, 1857–8.

Ordinary—	
Land tax..	L.1,546,752
Excise and stamps..........................	275,123
Nuzurana tribute, &c.........................	42,025
Postal, &c.	31,894
Miscellaneous..................................	47,552
Toshakhana......................................	9,976
Total ordinary..............................	L.1,953,322
Extraordinary..................................	522
Local funds	99,227
Grand total...................................	L.2,053,071

Expenditure, 1857–58.

Ordinary—	
General...	L.60,421
Judicial...	229,995
Revenue	148,573
Excise and stamps...........................	31,508
Postal, &c..	152,485
Miscellaneous..................................	46,591
Military...	771,704
Toshakhana.....................................	9,923
Total ordinary...............................	L.1,451,200
Extraordinary—	
Settlement and survey......................	15,942
Public works....................................	224,994
Miscellaneous	3,643
Total extraordinary	L.244,579
Local funds	70,897
Grand total	L.1,766,676

The expenditure for the year 1857–8 was considerably affected by the unsettled state of the country at that time. There was an increase of 8 per cent. on judicial charges for extra police; and on the other hand there was a more than corresponding reduction in public works. In military charges the difference was great; some 77 lakhs being charged this year, instead of 50 lakhs in the preceding years. It is to be observed, however, that the income did not materially fall off during that year. Under the expenditure are included all charges for civil and political establishments, works of public improvements, &c., but not charges for the regular army or the construction of cantonments. The outlay on public works for the last two years, together with the total previous expenditure, was as follows :—

	1856–7.	1857–8.	Previous Expenditure.	Total.
	L.	L.	L.	L.
Roads	60,141	55,162	1,122,460	1,237,763
Canals............	171,841	127,000	715,300	1,014,141
Miscellaneous...	17,433	7,147	265,500	290,080
Military	207,526	114,097	1,142,100	1,463,723
Total......	456,941	303,406	3,245,360	4,005,707

Principal cities.

In the Trans-Satlej states the only town of any importance is Jalandar, which contains a population of about 40,000. In the Láhor division the two principal cities are Láhor and Amritsir. Láhor, in N. Lat. 31. 36., E. Long. 74. 21., is situated a mile E. of the Raví River. It is surrounded by a fortification 7 miles in circuit. The citadel is on the N.W. angle of the city, and contains vast magazines of stores. There are many fine mosques, of which the *Pádsháh masjid*, built by Aurangzíb, and the mosque of Vazír Khán, are the most remarkable. Three miles to the west, across the Raví, is the mausoleum of Jahángír, quadrangular, with a minaret 70 feet high at each corner, and built of red sandstone. About the same distance to the N.E. is the famous garden of Sháh Jahán, called the *Shálinár*, or "House of Joy." It contains 450 fountains, and has three terraces rising one above the other. The population of Láhor is reckoned at 95,000. This city was taken byMahmúd of Ghazní in 1009, and in 1152 became the capital of the Ghaznivite dynasty. In 1186 it was taken by Sáhibu'd-Dín, of the House of Ghor, and in 1523 by Bábar. In 1748 it fell into the hands of Ahmad Sháh Durrání; and in 1799 Ranjít Singh was made governor by Zamán Sháh, and soon established his independence.

---

[1] *General Report from* 1854–55 *to* 1855–56, p. 72.

Amritsir (" The Fount of Immortality"), in N. Lat. 31. 40., E. Long. 74. 45., is situated about 30 miles E. of Láhor. It has its name from a sacred tank made by Rámdás, the fourth *guru*, or spiritual teacher of the Sikhs, in 1581. The tank is 150 paces square, and is filled with beautifully clear water. In the centre is an island with a temple to Vishnu, which blazes with gold and ornaments. The trade of the place is very great, and some of the richest merchants in India reside here. One of this class about twenty-five years ago established a banking-house at St Petersburg, and died worth millions of rubles. The city is completely commanded by the huge fortress of Govindgarh, built by Ranjít Singh in 1809, under the pretence of protecting the sacred spot, but in reality to overawe the turbulent multitudes that assembled there. The population of Amritsir is reckoned at 90,000. Siyálkot, in N. Lat. 32. 29., E. Long. 74. 33., with 20,000 inhabitants; Rámnagar, in N. Lat. 32. 20., E. Long. 73. 50, a large town; Wazírábád, with 17,000 inhabitants, in N. Lat. 32. 27., E. Long. 74. 10.; and Gujaránwálá, in N. Lat. 32. 10., E. Long. 74. 13., the original residence of Ranjít Singh's family, are also in this division. Wazírábád is the handsomest town in the Panjáb, having been rebuilt on a regular plan, with wide streets and a fine bázár, by General Avitabile.

In the Multán division the city of that name is the only one of great note. It stands in N. Lat. 30. 12., E. Long. 71. 30., 3 miles E. of the Chenáb. According to Burnes, its name is properly *Mallithán* (" The City of the Malli"), taken by Alexander. It is more certain that it was captured by Muhammad-bin-Kásim in the close of the eighth century, by Mahmúd of Ghazní at the beginning of the eleventh, and by Tímúr in the fourteenth. In 1828 it was stormed by Ranjít Singh with great slaughter on both sides. The conqueror is said to have lost 10,000 men out of 25,000 during the siege, and the garrison of 3000 Afgháns were all put to the sword. In 1848 the Governor Múlráj murdered two British officers, which led to the campaign in which Major Edwardes so much distinguished himself. On the 2d of January 1849 the city was taken by General Whish; and the citadel surrendered on the 22d. The population is reckoned at 81,000.

The towns in the province of Leia are none of them very large or populous, but their size and population are increasing with most rapid strides, and under the peaceful rule of the English it may be predicted they will soon grow up into great cities. Leia, in N. Lat. 30. 57., E. Long. 71. 4., has now 15,000 inhabitants, though Elphinstone in 1807 describes it as a poor place, of about 500 houses; but situated in the midst of a country producing great quantities of indigo, sugar, silk, and cotton, and being on one of the principal roads from India to Afghánistán by the Kahirí ferry, the trade of Leia, both direct and transit, is very great. In the Deraját, the slip of country across the river from Leia, and between the Indus and the Sulaimán Mountains, the principal towns are Derá Ghází Khán, in N. Lat. 30. 4., E. Long. 70. 54.; Derá Fath Khán, in N. Lat. 31. 9., E. Long. 70. 50.; and Derá Isma'íl Khán, in N. Lat. 31. 50., E. Long. 70. 58. These places were originally, about three centuries ago, mere encampments of Bilúch chiefs, but grew up into towns, and are now places of great trade. Derá Ghází Khán has a population of about 15,000; the bázár containing 1600 shops, of which about 600 belong to weavers and cloth-sellers. The Lohání Afgháns carry on a brisk transit trade through this town. Of the other two Derás, that of Isma'íl Khán has a population of about 10,000. The trade in grain and in salt from Kálá Bágh is very considerable; but the most important dealings are in cotton cloth, of which two millions of yards are annually sold here, while eighteen millions of yards pass through.

Jílam, in the division so named, is a large town on the right bank of the River Jílam, in N. Lat. 32. 56., E. Long. 73. 47. The steamers from Karáchí are to ascend as far as this place. The river is crossed here in the cold season by a dangerous ford, which is 500 yards across, and has about 3 feet water running like a sluice. In December 1839, when the English army crossed here on their return from Kábul, an officer and ten men were drowned at this ford. Pind Dádan Khán, in N. Lat. 32. 36., E. Long. 73. 5., also on the right bank of the Jílam, is a town with 14,000 inhabitants. It is close to the Salt range, and a vast quantity of salt is raised in the vicinity. Ráwal Pindí, in N. Lat. 33. 37., E. Long. 73. 6., between the Indus and the Jílam, has a population of 16,000, with a considerable transit trade. It is the capital of a large district. Here Sháh Shujá, on his expulsion from Kábul, long resided, and a brick building erected by him is still dignified with the name of " The Palace."

Peshâwar, the capital of the division so called, lies in N. Lat. 34., E. Long. 71. 38. It is the portal of the Khaibar Pass, being 18 miles E. of the eastern extremity of that formidable defile. At the beginning of the present century the city was thought to contain 100,000 inhabitants; but it suffered much from Ranjít Singh, who, after his victory over the Afgháns at the battle of Naushahra, on the 14th of March 1823,[1] sacked Peshâwar, demolished most of the fine buildings, and laid waste the surrounding country. The population at present is reckoned at 541,000, exclusive of a very strong British force in cantonments, numbering about 10,000 men.

Races.

The cradle of the Sikhs is the tract called the Mánjha, or " Middle Land;" the Barí Doáb, between the Beah and the Raví; and to the south of the former river the district called Málwah, around Bhutinda and Sunâm. There are, however, in both the Mánjha and Málwah, many Bhattís, Dogras, Patháns, and Gujars, who are numerous everywhere in the Panjáb, but came originally from Gujarát. In the territory of Rambír Singh the mass of the population are Dogras and Kanets to the east; while in the hills south of Kashmír, and west to the Indus, are Gikkars, Gujars, Khatirs, and Awâns. The people of Kashmír are a very mixed race;[2] their language is Hindú, their faith that of Islam. Among the agricultural population Jats are numerous, and there are besides many wandering tribes, of whom the Changgars are thought to be the same as the Zigeuners, Gitanos, or Gypsies.

History.

The country through which the Indus flows is repeatedly mentioned in the *Vedas*. It was at the Vaidik era the abode of the Aryan nation, which was then passing slowly into India, which it now so completely occupies. The brief notices in the *Vedas* of the countries bordering on the Indus prepare the inquirer to believe the accounts of the teeming population and abundant resources those countries are said to possess in the chronicles of the campaigns of Alexander the Great. After Taxilas and Abisares, kings of the most western part of the Panjáb, had submitted, Porus, King of the Jech Doáb, encountered Alexander on the eastern shore of the Jílam. He had with him about 30,000 foot,[3] 4000 horse, and 200 elephants; and his troops fought with a courage not inferior to that of their hardy descendants in these more recent times. It is impossible to trace the exact progress of the Macedonians after the defeat of Porus. Suffice it to say, that it was successful, and that the Græco-Bactrian kings exercised a powerful influence, if they did not actually govern, some provinces of the Panjáb for centuries after the death of Alexander. The Muslimán first made their appearance in the Panjáb in the seventh century, when, under the generals of the Khalífah Walíd, they conquered Multán. In 977 A.D., Sabuktagín, King of Ghazni, ravaged the Panjáb, and subsequently several times invaded that country, over detached provinces of which he established his rule, as at Peshâwar, where he left a governor. Mahmúd, son of Sabuktagín, commenced his celebrated invasions of India in the year 1000 A.D. He repeatedly overran the Panjáb, incorporated the province of Multán and some other districts with his dominions, took many cities and forts, including Láhor, and established a continuous rule over the greater part of the kingdom of the Five Rivers. In 1152 A.D. Bahrâm, a descendant of Mahmúd, was expelled from Ghazní by Alláh of the House of Ghor, but retained Láhor and his Indian dominions, which thus became a separate monarchy until 1184 A.D., when Muhammad Ghori, King of Ghazní, took Láhor from Khusrau II., and extinguished the so-called dynasty of Ghazní. His career of victory was terminated in 1205 A.D. by the Gikkars, a wild tribe who raised a rebellion in the Northern Panjáb, and twenty of whom, having pledged themselves to destroy the king, forced their way into his tent at night, and stabbed him to death. From this date commenced the rule of the Pathán kings of India. Two of the great officers—Eldúz and Kutb—succeeded Muhammad, and divided his empire; Eldúz keeping all to the west of the Indus, and Kutb the Indian territories of which he was already viceroy. As he was originally a slave, the dynasty he founded was called that of the Slave Kings. Their capital was Delhi; and thenceforward the Panjáb sank into a province, until raised by Ranjít into an independent kingdom. In order to trace the rise of the Sikh power, it is necessary to begin with the history of the founder of their religion. Nának, their first *guru*, or teacher, was born in 1649 A.D. at Talwandí, a village on the Raví, above Láhor; or, according to one good authority,[1] at Kánakásh, 15 miles S. of Láhor. He died A.D. 1539 at Kartárpúr, on the Raví, 40 miles above Láhor, leaving many disciples or "Sikhs," a term which is now generally applied to all Hindú Panjábís. He taught belief in one God the Creator, self-existent, incomprehensible, sole, timeless, everlasting; that good deeds are nothing of themselves, and that the only true wisdom is the knowledge of God; that this knowledge is only attainable through the grace of God, but that it must be linked with good works for the attainment of salvation. He adopted the Hindú idea of the transmigration of the soul, and regarded beatitude as the dwelling with God after this punitory course is over. His doctrines have been handed down in a book called the *Granth*, which was composed not many years after his death, and is still revered as the scripture of the Sikhs. Nának left two sons, of whom one, named Shrí Chand founded the Hindú sect of *Udásís*,[2] ascetics who renounce the world. Angad was the second Sikh guru. He occupied himself chiefly with committing to writing the doctrines of Nának, and died in 1552 A.D. at Kaddúr, on the Beah. He was succeeded by Amardás, who composed part of the *Granth*, and died in 1574 A.D. The fourth guru was Rámdás, who established himself at Amritsir, and died in 1581. He is said to have been much esteemed by Akbar the Great. Arjun his son became the fifth guru, and arranged and published the *Granth*. The Emperor Jahángír imprisoned him on a charge of treason, and impaled 700 of his followers. He died, probably from the rigour of his confinement, in 1606, and was succeeded by his son Har Govind, the sixth guru, who first laid aside the peaceful tenets of Nának for the warlike principles of the modern Sikhs. He died in 1645 at Kíritpúr, on the Satlej, after repeatedly defeating the imperial troops. Under his chieftainship the Sikhs had grown up to a numerous and martial community. His son Har Ráe succeeded as seventh guru, and died in 1661. His younger son Har Kishan, a boy of six, was the eighth guru, and died in 1664 at Delhi. Tegh Bahádur, son of Har Govind, was the ninth guru, and having opposed and defeated the imperial troops, was ignominiously put to death by Aurangzíb, and his body exposed in the streets of Delhi. That circumstance was one of the main inducements to the Sikhs to join the English in capturing Delhi and crushing the Bengal mutineers. Tegh Bahádur was executed in 1675, and for more than twenty years after his death his son Govind, the tenth and most famous of the gurus, lived in retirement, pondering revenge and the means of raising his oppressed followers to independence and power. It was he who instituted the Páhal or initiatory ceremony of the Sikhs, taught his disciples to call themselves Singhs or Lions, to let their locks grow, and to devote their energies to steel, which they were always to wear about their persons. He thus established the Khálsa or special government of the Sikhs, and soon entered upon a war with the troops of Aurangzíb. His two sons were slain, his followers dispersed, and he himself was obliged to fly to the deserts of Bhutinda, where he composed the tenth chapter of the *Granth*. After the death of Aurangzíb, Govind took service with Bahádur Sháh, and was murdered in 1708 at Nadarh, on the banks of the Godávarí, by the sons of an attendant whom he had himself put to death. A disciple named Bandah now headed the sect, and after a fierce struggle with the Muhammadans, was taken at Ghordáspúr in the Panjáb, which he had made his stronghold, carried to Delhi, and torn to pieces with hot pincers, after he had been first compelled to murder his own son. This was in 1716; and so hot was the persecution of the Sikhs that followed, that they are scarce heard of till 1738, when the invasion of Nádir Sháh gave them courage to re-appear as combatants. After various vicissitudes, they in 1756 captured Láhor; and their chief Jassá Singh struck a coin with the inscription, "Coined by the grace of the Khálsa in the country of Ahmad, conquered by Jassá the Kalál." They were soon after, however, compelled to surrender Láhor to the Maráthas, who in turn were crushed by Ahmad Sháh Abdallí at the decisive battle of Pánipat in 1761. During this campaign the Sikhs hung round the Durrání army, and plundered stragglers. They began, too, to erect forts; and Charat Singh, the grandfather of Ranjít, made his stronghold at Gujránwálá, whence in 1762 he repulsed the Afgháns. That year, however, Ahmad Sháh inflicted a terrible chastisement on the Sikhs at the battle of Ghalú Ghárá,[3] south of the Satlej, where 20,000 of them fell. Nevertheless in 1764 they recovered Láhor, struck coins, established a general assembly, and divided themselves into twelve *Misls*, or "confederacies." Ahmad Sháh made his last inroad in 1766, and the next year Charat Singh took the great fort of Rhotas, and the Bhangí Misl conquered as far as Ráwal Pindí. Charat Singh was killed in 1772 by the bursting of his matchlock, and was succeeded by his son Mahá Singh, who in 1784 rose to pre-eminent power. His son Ranjít was born in 1780, and was but eleven years old when his father died, and left him the first position in the Khálsa, to be still further improved by his own abilities. In 1798 Sháh Zemán, King of Kábul, took Láhor, but was compelled to retire by the rebellion of his brother Mahmúd. As a reward for transporting his guns over the flooded Jílam, he bestowed Láhor upon Ranjít. In 1802 Perron, Sindhia's general, made an engagement with Ranjít for a joint expedition to the Indus, and the partition of all the country south of Láhor; but this agreement came to nothing, and Perron was soon afterwards disgraced by Sindhia, and obliged to fly. In 1805 Jeswan Rao Holkar retreated before Lord Lake into the Panjáb; and by the treaty of the 24th of December of that year, was allowed to retire to his dominions. In 1806 Ranjít took Lodiána, and in 1807 Kassúr, whither in September 1808 Mr Metcalfe proceeded to form a league between the English and the Sikh ruler. It was not, however, till the 25th of April 1809 that a treaty was made between the two powers, which precluded Ranjít from extending his territory to the south, and which inaugurated a lasting friendship between him and the British. The Sikh chiefs of Sirhind and Málwa were declared independent of Láhor; and this was further confirmed by the proclamation of August the 22d, 1811, which also forbade them to encroach on one another. From that time till 1818 Ranjít was occupied in consolidating his power. In June 1818 he took Multán; and in July 1819 annexed Kashmír, and a few months afterwards Derah Gházi Khán. On the 14th of March 1823 he defeated the Afgháns in the great battle of Naushahra, and sacked Peshávar. The French generals Ventura and Allard had taken service with him the year previous, and his troops had now all the discipline of regular battalions. In October 1831 an interview took place between Lord W. Bentinck and Ranjít at Rúpar on the Satlej; and on the 17th of July previous a present of horses from the King of England arrived at Láhor, under the escort of Lieutenant Burnes. On the 26th of June 1838 the famous tripartite treaty between the English government, Sháh Shujá, and Ranjít, was concluded, which led to the Afghán war, the restoration of Sháh Shujá to his kingdom, and in the end to his murder and the expulsion of his English allies. Ranjít died before these events, on the 27th June 1839, and was succeeded by his only legitimate son Kharg Singh; but on the 8th of October Kharg Singh was seized and confined by his son Náo Nihál Singh, and died on the 5th of November 1840, poisoned by small doses of corrosive sublimate.[1] On the same day, as Náo Nihál Singh was returning from attending the funeral rites to his father, a gateway fell on him, killed the son of Rájá Guláb Singh, who sate by his side, and so injured him that he expired a few hours afterwards. This accident was owing to the treachery of Dhyán Singh, the prime minister, brother of Guláb Singh. Chand Kunwar, widow of Kharg Singh, now assumed the government; but on the 18th of January 1841 Sher Singh, an illegitimate son of Ranjít, attacked the citadel where Chand Kunwar was, and compelled her to recognise him as supreme. Chand Kunwar was murdered in June 1842, and Sher Singh on the 15th September 1843, by Ajít Singh; while at the same moment Pratáp Singh, the son of Sher, was killed by Lehna Singh. These murders were committed with the aid and assent of the minister Dhyán Sing, who was immediately afterwards shot by the conspirators. Hírá Singh, the son of Dhyán, a few days after revenged his father's death by killing both the above-named assassins; and Dhalíp Singh, said to be a posthumous child of Ranjít, was proclaimed king, with Hírá Singh as minister. Many murders and insurrections followed; and on the 21st December 1844 Hírá Singh was put to death. He was succeeded by Jawáhir Singh, who was shot by the soldiery on the 21st of September 1845; and Lál Singh was then made by them prime minister. The Sikh army had now for some time been utterly unmanageable; the English agent for Sikh affairs, Major Broadfoot, rather urged on than deprecated a collision; and on the 17th of November 1845 the Khálsa declared war against the English, and the Sikh troops crossed the Satlej on the 11th of December. On the 18th the battle of Mudkí was fought. The English under Lord Gough numbered 11,000; and had 215 killed and 657 wounded. The Sikhs had about 4000 infantry, 10,000 horse, and 22 guns, of which 17 were taken by the English. On the 21st Sir J. Little joined Lord Gough with a fresh division, and the English advanced to storm the Sikh position at Fírúzshahr, where they had 12 regiments of infantry,[2] 10,000 horse, and 100 guns. The combat ended doubtfully, though the English captured many guns, and 2000 of the Sikhs fell. But the English lost 694 killed and 1721 wounded; and nothing but the treason of the Sikh general Tej Singh, whose object was to crush his mutinous army, alone saved them. The campaign was closed by the decisive battle of Sobráon on the 10th of February 1846. The English loss was 320 killed and 2083 wounded; but the Sikhs had at least 5000 killed, and all their guns and baggage taken. On the 9th of March 1846 a treaty was concluded between Dhalíp Singh and the English, by which the Maharájá renounced all claim to territory south of the Satlej; ceded the Doáb between the Beah and Satlej, and the hilly countries between the Beah and Indus, including Kashmír and Hazára; paid 5,000,000 rupees; disbanded all but 25 regiments of infantry, and 12,000 horse, recognised the independence of the Jamu state; and agreed to other terms which placed the Panjáb in dependence on the British government. This treaty, however, was soon disturbed by an outbreak in Multán. Sáwan Mall, the able governor of this province under Ranjít, was murdered in September 1844, and was succeeded by his son Múlráj. His exactions and misrule led to an order for his deposition; and in 1848, when the English were acting as advisers to Dhalíp Singh, Mr Vans Agnew and Lieut. Anderson were sent to depose him, and instal Khán Singh as his successor. On the 18th of April 1848 they were attacked and murdered; and the second Sikh war broke out. The news reached Lieut. Edwardes on the 22d at Derah Fath Khán, where he was on political employ. He had with him 1 infantry regiment, with 4 extra companies, 2 guns, 20 swivels, and 350 horse. On the 25th he reached Leia, and commenced raising levies; and, being joined by the troops of Bháwalpúr, held Múlráj in check. Ere long, however, the old Sikh army joined the rebels, and Multán was not taken by the English till the 2d of January 1849. On the 15th of that month the indecisive battle of Chiliánwálá was fought, in which the English under Lord Gough had 22 European officers and 580 men killed, 67 European officers and 1678 men wounded or missing. The Sikhs under Sher Singh suffered far less. Several other sharp actions were fought; and the campaign ended on the 21st of February 1849 by the decisive victory of Gujarát, in which the English loss was 5 European officers killed and 24 wounded, 93 men killed and 677 wounded or missing. The Panjáb was then permanently annexed, and has ever since continued under the British government. The news of the outbreak of the late rebellion reached Peshávar on the 11th of May, the very day it occurred at Mírat.[3] There were then at Peshávar H.M.'s 70th and 87th regiments, 2 troops of European horse artillery, 2 companies of artillery, the 5th Bengal light cavalry, the 21st, 24th, 27th, 51st, 64th Bengal native infantry, the regiment of Khiláti Ghilzye, the 7th and 18th Bengal irregular cavalry; in all about 12,000 men, of whom 2570 were Europeans. At Naushahra were her H.M.'s 27th regiment, the 55th Bengal native infantry, the 10th irregular cavalry, and an artillery mountain train. At Atak were a detachment of the 58th Bengal native infantry, a company of artillery, and one of sappers and miners; and close by at Shamsábád the 17th irregular cavalry. At Mardán, in the Yúsufzye country, was the now famous corps of guides. At Ráwal Pindí was H.M.'s 24th regiment, the 58th Bengal native infantry, the Kumáon battalion of Gorkhas, the 16th irregular cavalry, and 1 troop of native horse artillery. Jílam was garrisoned by the 14th and 39th native infantry, and a native light field battery. H.M.'s 52d regiment, and a European troop of horse artillery held Siyálkot with the 35th and 46th Bengal native infantry, and 9th light cavalry. At Láhor were H.M.'s 81st regiment, with 2 troops of horse artillery and 4 companies of reserve artillery,—all Europeans; with the 16th and 26th light infantry, and 8th light cavalry. Close by at Amritsir were the 59th Bengal native infantry, with a light field battery, and a company of European reserve artillery in the strong fort of Govindgarh. Ghordáspúr was held by the 2d irregular cavalry; Kángra by the left wing of the 4th Bengal native infantry and half a company of native artillery; Núrpúr by a similar force of artillery and the other wing of the 4th native infantry; Hushyarpúr by the 33d native infantry, 9th irregular cavalry, and 1 troop of native horse artillery; Phillaur by the 3d native infantry; Jalandar by H.M.'s 8th regiment, a troop of European horse artillery, the 36th and 61st native infantry, and 6th light cavalry. At Fírúzpúr were H.M.'s 61st regiment, a European light horse battery, a company of European artillery, the 45th and 57th Bengal native infantry, and 10th light cavalry. At Multán were the 62d and 69th native infantry, 1st irregular cavalry, and a troop of native horse artillery. At Ambálah were H.M.'s 9th dragoons, 2 troops of European artillery, the 5th and 60th native infantry, and 4th lancers natives. In the adjoining Himálya range were the Nasírí battalion, H.M.'s 75th regiment, the 1st and the 2d Bengal fusiliers. To sum up, there were from Karnál to Pesháwar about 36,000[1] native troops, most of whom were Púrbiyahs from the same localities as the Mírat aud Delhi mutineers. Against these were 11 regiments of European infantry, 1 of cavalry, and 2000 artillery; in all about 10,500 men. There were, besides, 22,000 Panjáb troops interspersed with a fourth part of Hindústánís. Immediately after the outbreak 3 regiments of European infantry and 1 of cavalry marched against Delhi, leaving 7500 Europeans to watch 33,000 Hindústánís, for only 2 native regiments went to Delhi. The whole province of the Panjáb was to be held against such odds, the besieging army at Delhi was to be re-inforced, and the surrounding martial tribes kept in check. It was a prodigious task that was imposed on Sir John Lawrence, the chief civil officer in the Panjáb; but he nobly and successfully accomplished it. It was soon seen that the Hindústání regiments were ripe for revolt. On the 14th of May the 45th and 57th native infantry mutined at Fírúzpúr, and attempted to seize the great arsenal. The attempt failed, but most of the mutineers escaped. An outbreak at Láhor was prevented by dexterously disarming the native corps at Miyán Mír, the cantonment of Láhor, on the 13th of May. On the 21st the 55th mutinied at Mardán on seeing Europeans advancing to take their arms, and fled to the hills, but nearly all perished. On the 22d, the 5th light cavalry, the 24th, 27th, and 51st, were disarmed at Pesháwar, and the 10th irregular cavalry at Naushahra on the 26th. On the 7th and 8th of June the 3d, 36th and 61st native infantry, and 67th light cavalry, in the Jalandar Doáb, rose in revolt, and marched to Delhi. On the 1st the troops at Multán were disarmed; the 5th native infantry at Ambálah on the 15th; the 33d and 35th in Jalandar on the 25th; the 58th and part of the 14th native infantry at Ráwal Pindí on the 7th of July, on which day, however, the bulk of the 14th, seeing the Europeans approach, broke out, and were nearly all destroyed. Two days afterwards, the 46th and a wing of the 9th light cavalry mutinied at Siyálkot, and after murdering Brigadier Brind, Captain Bishop, two Drs Graham, the Rev. Mr Hunter, and others, the mutineers marched for Delhi by way of Ghordáspúr and Phillaur. They were overtaken at Núrpúr, 15 miles beyond that station, and, after a sharp struggle, all put to the sword. On the 30th of July the disarmed 26th fled from Láhor, but were overtaken and destroyed. The 10th light cavalry escaped from Fírúzpúr on the 19th of August. The 51st mutinied, and were destroyed at Pesháwar on the 28th of that month. On the 15th of July 259 men of the 4th light cavalry were disarmed at Ambálah; the 59th at Amritsir, seven days previous; the 4th at Hushyárpúr, three days previous; the 39th in the Deráját, one day previous. Thus 18 regiments, numbering 13,000 men, were disarmed without resistance; the native gunners of four batteries were removed from their guns, and their places supplied by European volunteers. The 21st native infantry, the regiment of Khil'ati-Ghilzye, and the 1st, 2d, 6th, 7th, 16th, 17th, and 18th regiments of irregular cavalry alone remained armed, and continue so to this day. But not only did Sir J. Lawrence hold the vast force of mutinous Sipáhís garrisoning the Panjáb in check, but he also detached powerful reinforcements to Delhi, without which that city would not have been taken, and India might have been lost. The first body of troops detached to act against Delhi were the 1st and 2d Bengal European regiments, and H.M.'s 75th, which went with General Anson. The siege train was then sent from Phillaur. Then followed a wing of H.M.'s 8th, and one of H.M.'s 61st, the guide corps, the 4th Sikhs, the 1st Panjáb infantry, the 1st, 2d, and 5th Panjáb cavalry, 300 Sikh artillerymen, and 1200 Sikh sappers and miners. General Van Cortlandt, with 1000 irregulars, cleared the western part of the Delhi territory. Lastly, General Nicholson led the remainder of H.M.'s 8th and 61st, the 52d, the 2d, 4th, and 7th Panjáb infantry, a siege train from Fírúzpúr, and the Kashmír contingent, against Delhi, leaving but 4500 European soldiers, sick included, to hold the Panjáb. Not a day had been lost in calling on the rájás of the protected Sikh states for their contingents. They nobly obeyed, to the number of eighty chiefs: the Rájá of Basáhir alone remained inactive. The Rájá of Jhínd was actually *the first man*, European or native, who took the field against the mutineers. He openly declared at once that he should side with the British, under whom he had lived happily for fifty years,—a speech which powerfully influenced the popular opinion. He marched with 800 men to Karnál, and thence in the van of the British troops advancing against Delhi, clearing the road for them, and procuring supplies. He held an exposed post during the siege; his troops guarded the ferry over the Jamná, on the road to Mírat, and shared in the final assault on the Kashmír gate. The Máhárájá of Pattiála supplied 5000 men, and kept open the road from Láhor to Delhi. The Rájá of Nabah held the fort of Lodiána. The Rájá of Kapúrthala, of high rank among Sikhs, next perhaps to the Rájá of Pattiála, furnished 2000 men, and, after serving in Jalandar, marched with his contingent into Oudh. The Rájá of Jamu supplied 2000 men. In short, the Sikh nation threw their sword into the scale against the rebels. A long-nourished hatred to Delhi and its people influenced them no doubt in this decision; but the stupendous fact remains, that England recovered her Indian empire mainly by the hands of those whom she had ten years before vanquished in many bloody battles. That administration must have been just, politic, and prosperous that could produce such a result. (E. B. E.)

[1] *Report on the Administration of the Punjáb*, 1856–58, section xi.

PUNNAH, a town of British India, capital of a territory of the same name in Bundelcund, near a large *jhil*, or artificial lake, on the north-eastern slope of the barren range of the Punnah Hills, 130 miles S. of Calpee, 173 S.W. of Allahabad, and 668 N.W. of Calcutta. Though once a fine town, it is now quite ruinous. Many of the streets, well paved and lined with handsome, substantial houses, are tenanted only by monkeys, which grin on the passers-by from the roofs and windows. The large and elegant palace of the rajah, and many Hindu temples, are the chief buildings in the town; and the people being almost all Hindus, there are no mosques here. Punnah was formerly an important place, chiefly on account of the diamond mines in the vicinity. Although the gems are still found here, the business is now much less profitable than it once was. On the shores of the *jhil*, or tank, near the town, there are many fine mausoleums. The alligators in the water are considered sacred by the Hindus.

PUNO, a department of Peru, bounded on the N.W. and N. by the department of Cuzco, E. and S.E. by Bolivia, S. and W. by the departments of Moquegua and Arequipa; area 25,918 square miles. It is partially occupied by a range of the Andes, extending northwards from the province of Carangas in Bolivia to Lampa in this department. The principal rivers are the Ramis, Coata, and Ilave, all flowing into Lake Titicaca, which lies to the S.E. of the department, separating it from Bolivia. Puno contains extensive and good pasturages; and cattle, potatoes, and barley are among it products. The silver mines in the department were at one time second only to those of Potosi; but they have been for some time very little attended to. The department is divided into five provinces, as follows:—

	Districts.	Population.	Capital.
Carabaya	13	22,605	Crucero.
Azángaro	16	54,333	Azángaro.
Lampa	18	76,488	Lampa.
Guancané	11	56,765	Guancané.
Chucuito	12	75,957	Juli.
Total	70	286,148	PUNO.

The town of Puno, the capital, stands on a bay of the same name on the western shore of Lake Titicaca, 12,832 feet above the sea, 90 miles E. by S. of Arequipa. It is regularly and well built, chiefly of stone; and contains a cathedral, high school, hospital, &c. Puno is the seat of a superior court of law. Pop. 8000.

PURBACH, George. See Dissertation Fourth, section iv.; and Astronomy, *History of*.

PURBECK. See Dorsetshire.

PURCELL, Henry, the most celebrated of English musicians, was born at London in 1658, and died there on the 21st of November 1695. His father was a gentleman of the chapel royal, who died in 1664. It appears that Purcell received lessons in music from Cook and Humphrey and Dr Blow; and at the early age of eighteen was appointed organist of Westminster Abbey. In 1682 he was made organist of the chapel royal on the death of Low, the successor of Dr Christopher Gibbons. He began very early to compose music for the church, as well as for the theatre and the chamber; and superior genius and skill were shown in all his compositions. His music for the theatre and the chamber was exceedingly popular, and many of his compositions for the church still hold their place in the chapel royal and in English cathedrals.

Unlike some other English composers, Purcell was always ready to confess his obligations to those Italian models which he had studied. In the preface to his first set of Sonatas, 1683, he tells us that "he has faithfully endeavoured at a just imitation of the most famed Italian masters; and he thinks (though unskilled in the language of that country) he may warrantably affirm that he is not mistaken in the power of the Italian notes, or elegancy of their compositions." And again, in the dedication of the Score of his opera of *Dioclesian* (1691) to the Duke of Somerset, Purcell says,—"Musick is yet but in its nonage; a forward child, which gives hope of what it may be hereafter in England, when the masters of it shall find more encouragement. 'Tis now learning *Italian*, which is its best master. We must shake off our barbarity by degrees." If we find occasional crudity and harshness in the music of Purcell, we must consider that in his time musical composition was in a state of transition from rigid scholastic rules to the freedom of musical fancy. Dr Burney severely blames Purcell for using the chord of minor 6th with major 3d, and calls it "jargon;" but it so happens that this chord was freely used afterwards by the Bachs, Haydn, Mozart, Beethoven, Cherubini, and other eminent composers. Purcell's tomb and monument are in Westminster Abbey. His fertility in composition was wonderful. A great quantity of sacred music by Purcell remained in manuscript, when Mr Vincent Novello of London undertook to collect and edit the whole of Purcell's church music. This work appeared in 1826–36, in large folio, with a portrait, and an essay on the life and works of the composer. (G. F. G.)

PURCHAS, Samuel, an English divine, famous for compiling a valuable collection of voyages, was born in 1577 at Thacksted in Essex. After studying at Cambridge, he obtained the vicarage of Eastwood in his native county; but leaving that cure to his brother, he settled in London, in order to carry on the great work on which he was engaged. He published the first volume in folio in 1613, and the last four twelve years afterwards, under the title of *Purchas, his Pilgrimage, or Relations of the World, and the Religions observed in all Ages and Places.* Meanwhile he was collated to the rectory of St Martin's, Ludgate, in London, and made chaplain to Dr Abbot, Archbishop of Canterbury. His *Pilgrimages*, and the learned Hakluyt's *Voyages*, led the way to all the other collections of the same kind, which have been so justly valued and esteemed. (See Hakluyt, *Richard.*) But unhappily, by publishing, he involved himself in debt, and died in embarrassed circumstances about the year 1628. He likewise wrote *Microcosmus, or the History of Man*, 8vo, 1619; *The King's Tower and Triumphant Arch of London*, 8vo, 1623; and a *Funeral Sermon on Psalm* xxxix. 5, 8vo, 1619. A foreign writer describes him as "an Englishman admirably skilled in languages and human and divine arts; a very great philosopher, historian, and theologian; a faithful priest of his own church; very widely known for his many excellent writings, and especially for his large volumes pertaining to the East and West Indies."

PURGATORY, a place in which the just, who depart out of this life, are supposed to expiate certain offences which do not merit eternal condemnation. Broughton has endeavoured to prove that this notion was held by Pagans, Jews, and Mohammedans, as well as by Christians; and it cannot be questioned that, in the days of the Maccabees, the Jews believed that sin might be expiated by sacrifice after the death of the sinner. The following view of it is taken from a work which is considered as a standard by Roman Catholics:—First, every sin, how slight soever, though no more than an idle word, as it is an offence to God, deserves punishment from him, and will be punished by him hereafter, if not cancelled by repentance here. Secondly, such small sins do not deserve eternal punishment. Thirdly, few depart this life so pure as to be totally exempt from spots of this nature, and from every kind of debt due to God's justice. Fourthly, few will therefore escape without suffering something from his justice for such debts as they have carried with them out of this world, according to that rule of divine justice by which he treats every soul hereafter according to its works, and according to the state in which he finds it in death. From these propositions, which the Roman Catholic considers as so many self-evident truths, he infers that there must be some third place of punishment; for since the infinite goodness of God can admit nothing into heaven which is not clean and pure from all sins, both great and small, and as his infinite justice can permit none to receive the reward of bliss who as yet are not out of debt, but have something in justice to suffer, so there must of necessity be some place or state where souls departing this life, pardoned as to the eternal guilt or pain, yet obnoxious to some temporal penalty, or with the guilt of some venial faults, are purged and purified before their admission into heaven. This is what the Roman Catholic is taught concerning purgatory; and though he knows not where it is, of what nature the pains are, or how long each soul is detained there, yet he believes that those who are in this place, being the living members of Jesus Christ, are relieved by the prayers of their fellow-members here on earth, as also by alms and masses offered up to God for their souls. And as for such as have no relations or friends to pray for them or give alms, or procure masses for their relief, they are not neglected by the church, which makes a general commemoration of all the faithful departed in every mass, and in every one of the canonical hours of the divine office. The Protestant Church considers this doctrine to be "grounded on no warranty of Scripture."

PURITANS. See Nonconformists.

PURNEAH, a district of British India, in the presidency of Bengal, bounded on the N. by Nepaul and Sikhim, E. by the district of Dinagepore, S. by those of Malda and Bhaugulpore, and W. by that of Bhaugulpore: length, from N.E. to S.W., 117 miles; breadth, 105; area, 5878 square miles. It is low and flat, having no mountains or hills more than 275 feet above the sea. It is watered by the Ganges at its south-eastern extremity, and by the Kosee, Gogaree, and Mahanunda, affluents of that river. These and other smaller rivers are generally navigable for vessels of considerable size. The climate in the end of spring and beginning of summer is hot and dry; in the latter part of summer the rainy season sets in, and in winter the cold is often considerable. Rice is the principal crop raised; but wheat, barley, pulse, maize, millet, &c., are also cultivated. Sugar, cotton, tobacco, &c., are grown; and indigo is the chief article of commerce produced in the district. Some trade is carried on with the adjacent British districts and with Nepaul; cattle, grain, cotton stuffs, silks, and indigo being the chief exports. Pop. 1,600,000.

Purneah, the capital of the above district, on both sides of the Little Kosee, 283 miles N.W. of Calcutta. It covers a wide space of ground, but this is partly occupied by gardens and plantations. The principal street, which is on the left side of the river, is broad, straight, and lined with good tiled houses. The only public building of importance is that which accommodates the civil establishment for the district, and which stands in one of the suburbs. Pop. nearly 50,000.

PURSER. See Navy, "Paymaster."

PUSHKIN, Alexander Sergejewitsh, the most distinguished poet of Russia, was born on the 26th of May (June 7) 1799. He was sprung from an ancient Russian family, whose name figures in the history of the country, and who is introduced among the *dramatis personæ* of one of the poet's historical plays. He was likewise of Moorish descent. The daughter of Hannibal, a Moor whom Peter the Great bought and bred into a general, had married the great-grandfather of the poet, and, if we may trust the testimony of a bust, transmitted a tint of the Moorish blood to the young genius, who, in a few generations, was to render her family immortal. During his early education he seems to have showed capabilities of the first order. He entered the lyceum at Tsarskoe-selo in 1811, where he was distinguished for general ability and for an excellent memory; but he seems to have been deficient in concentrative power (such, at least, as the lyceum required), and too frequently squandered his time in aimless pleasures. Here he began to sow his wild oats, and wrote, amid much youthful fervour and excitement, numerous poetical pieces. His *Ruslan and Ljudmila*, a tale in verse after the manner of Ariosto's *Orlando Furioso*, closed the first period of his irregular poetical career. He had for his teachers at the lyceum Dershawin, Shukowski, and Kunitzin, men whom the poet ceased not to mention with respect and admiration, and two of whom were then the most celebrated poets of Russia. At the age of eighteen (1817) he left the institution and entered the civil service. He obtained a situation in the department for foreign affairs, and, full of the ardour of youth and of a fiery, poetic temperament, he found himself at once amid the gay and brilliant circles of the northern capital. The poem just referred to was written at the age of one-and-twenty. It was a real work of art. The critics attacked it because it was new and out of their line, and the public devoured it. It may be considered as the first great poetical work in the Russian language, and from it dates an important era in Russian literature. He now entered on his second period—a period characterized by a revolutionary spirit and a tone of disappointment and scepticism. It begins with *Plennik Kavkaskoi*, or "Prisoner of the Caucasus" (1822), and ends with the greatest and most remarkable of his works, *Eugene Onegin* (1825–1828). His *Ode to Liberty* cost him his freedom, and he was exiled to Bessarabia from 1820 to 1825. During this period his lyrical pieces give us his mental autobiography. In his more deliberate compositions Lord Byron exerted a great influence over the poetical development of Pushkin. The poets are similar in their form; their heroes and heroines resemble each other; and Pushkin's gloomy colouring and mysterious connection between guilt and fate always remind the reader of the great English poet. This Byronic phase of Pushkin's development closed with this second period, when he stepped forth into entire artistic independence and nationality. The poet returned from his Caucasian retirement at the invitation of the new emperor Nicholas, shorn of much of his bacchanalian wildness and license, and prepared to enter upon the third and the closing period of his career. He accepted, under a regime of terrorism, the office of historiographer of Peter I., with an annual salary of 6000 rubles (L.1350). He was now looked upon as a traitor to the cause of liberty; but three years of exile to the mouths of the Danube had probably cooled his enthusiasm. As the first fruits of his new office, he, in 1827, wrote a history of the insurrection of Pugatsheff. He passed the season of autumn, his favourite period for literary production, at his country seat, Michailowsk, in the province of Pskoff, in the company of an old nurse to whom he read the MSS. of his new works. In 1829 he published his historical poem *Poltawa*, a highly poetical representation of the time when his country began its great development under Peter the Great. To the same period also belongs his historical drama of *Boris Godunoff*, which some critics place next *Onegin* in point of poetical beauty. As a dramatic work, however, it is inferior to his *Stone Guest* (1836). During the same year (1829) he followed the triumphant march of Field-Marshal Paskiewitsch to Erzeroum, and in February 1831 he married. The handful of years which were yet in store for him were years of unmingled happiness. He wrote the charming novel, *The Daughter of the Captive*, and took an active share in the publication of a periodical called *The Reading Library*. He likewise published some of his most finished poems, and kept working at his *History of Peter the Great*, an achievement which he was not destined to complete. On the 27th of January 1837, Pushkin, who had become involved in a duel with one Van Heeckerin, a foreigner, received a wound which proved mortal on the 29th of the same month (February 10). Thus died the greatest poet which Russia has yet known, in the prime of his manhood and in the meridian of his genius. The emperor showed great kindness to the poet's widow and family, and commanded a splendid edition of his whole works to be published at his own expense. See *Sotchinenia A. Pushkina, isdanie Anenkova* ("The works of A. Pushkin, edited by Anenkov"), 7 vols., St Petersburg, 1854–57. (See the *National Review* for 1858.)

PUTEOLI (the modern *Puzzuoli*), a maritime city of Campania, was situated on the eastern shore of the Gulf of Baiæ. A colony from the neighbouring Greek city of Cumæ founded it. It was originally called *Dicæarchia*, and it afterwards acquired the name of Puteoli, from the wells (*putei*) in the vicinity. But the town was of no note in the history of the country until the second Punic war. At that time the Romans began to take advantage of its finely-sheltered harbour. They first used it in their warlike operations against Hannibal. After the war was finished, they made it the emporium of their eastern commerce. A powerful stimulus was in consequence given to the prosperity of the city. Its shore and vicinity, after the lapse of several years, presented a pleasing picture of thriving opulence. Some ships bound for the Turdetanians in Spain, with Italian produce, were hoisting their sails in the bay; others from Alexandria were unlading their cargoes of corn and costly wares along the arch-supported mole which ran out into the sea. From the extensive docks rose the huge skeletons of the vessels which were being built for the purpose of transporting the large obelisks from Egypt. Conspicuous among the houses on the shore, and surrounded with busy traffic, stood the factories of merchants from the Phœnician cities of Tyre and Berytus; while, studding the hills in the background were seen the palatial villas of the Roman patricians, and among others the famous *Academia* of the great Cicero. This prosperity seems to have continued during the entire period of the supremacy of the Romans. On the dismemberment of the empire, however, Puteoli began to sink in importance, and a series of dire calamities accelerated its decline. Alaric and Genseric plundered it in the fifth century. The devastation was completed not long afterwards by an earthquake and the subsidence of the land. It was re-peopled in the eighth century only to be assailed once more with severe disasters. In the ninth century the Lombard dukes of Benevento reduced it. In 1198 the eruption of the volcano of Solfatara damaged it considerably; and in 1538 the upheaval of Monte Nuovo caused it to suffer again under volcanic agency. The Puzzuoli of the present day is a poor unhealthy town of 10,000 inhabitants. The only traces of its ancient grandeur are some ruins, consisting of a building commonly called the temple of Serapis, a range of baths, a temple of Neptune, a mole, an amphitheatre, and a theatre.

PUTIVL, a town of European Russia, in the government of Kursk, on the Seim, 100 miles W.S.W. of Kursk. It is an ancient place, pretty well built, for the most part of wood; and it contains numerous churches, a convent, school, and two benevolent institutions. Vitriol, saltpetre, tiles, &c., are manufactured here; and an active trade in rural produce is carried on. Pop. (1849) 4310.

PUTNEY, a village and parish of England, in the county of Surrey, on the right bank of the Thames, opposite to Fulham, with which it is connected by a wooden bridge, 6 miles S.W. of St Paul's. The old church, which was partially rebuilt in the time of Henry VII., contains some interesting tombs and monuments. Besides places of worship for Independents and Wesleyans, Putney has national infant, and endowed schools. It is celebrated as the birth-place of the historian Gibbon. Pop. of the parish (1851) 5280.

PUTREFACTION. See Fermentation.

PUTTEE, a town of British India, in the Punjab, about 12 miles from the W. bank of the Beas, and 38 S.E. of Lahore. The most of the streets are paved, and the houses built of brick. The fertile and populous country in the vicinity is thought to be peculiarly suited for breeding horses, and there is a large government stud at Puttee. Pop. about 5000.

PUTTEEALA, a town of British India, capital of a dependent native state of the same name, in Sirhind, on the Kosilla, 1023 miles N.W. of Calcutta. It is walled, and has a citadel of no great strength, where the rajah resides. The town is compactly built of brick; and has a more neat and cleanly appearance than most Indian towns, notwithstanding its dense population. The territory of the state, which has an area of 4682 square miles, is very fertile, and exports grain in large quantities. It was taken possession of by the British in 1809; but the rajah retains the sovereignty, on condition of furnishing a certain number of troops in case of war to the British government. Pop. of the state 1,310,960.

PUTTUN, a town of British India, in the presidency of Bombay, and province of Guzerat, on the Saraswati, an affluent of the Banas, 63 miles N.W. of Ahmedabad. It is surrounded by a wall, partially built from the ruins of the ancient city of Anhulwara, whose site can still be traced. Several important manufactures are carried on at Puttun, especially those of swords, spears, pottery, silk and cotton cloth. Pop. estimated at 30,000.

PUTTY is a kind of paste compounded of whiting and linseed oil, beaten together to the consistence of a thick dough. It is used by glaziers for fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots.

PUY, Le, a town of France, capital of the department of Haute-Loire, on the Borne, near the left bank of the Loire, 68 miles S.W. of Lyons. It presents an exceedingly picturesque appearance from a distance, on account of its remarkable and striking situation. Nearly the whole of the town is built on the steep slopes of a hill, which rises up in the centre to a scarped and flat-topped summit, crowned with an ancient castle. This rock, which is of volcanic formation on a calcareous base, is called the Rock of Corneille. A still more remarkable, though not so high rock is that of St Michael, which rises from the bank of the Borne, a short distance off. It is needle-like in shape, and its sides are almost perpendicular. The top is occupied by a small chapel dedicated to St Michael, to which access is gained by a winding stair partly cut in the rock. On a near view, Le Puy does not present so many charms to the visitor as at a distance, for it is ill-built, with narrow, irregular, steep, and ill-kept streets. In the loftiest part stands the cathedral, a heavy inelegant edifice in the Romanesque style. It is of considerable antiquity, and contains a richly-ornamented altar and a miraculous image of the Virgin. The Gothic church of St Laurent is chiefly remarkable for containing a monument of the celebrated Du Guesclin, whose entrails are buried here. Near the foot of St Michael's Rock stands an octagonal Romanesque building, long supposed to be a temple of Diana, but probably in reality a Christian baptistery. Le Puy has a good museum, especially rich in mineralogical and geological specimens, a public library, college, two hospitals, &c. Many of the women of the town are employed in making cotton lace. Woollen cloth, leather, nails, &c., are also manufactured; and an active trade is carried on here. Pop. (1856) 14,428.

PUY-DE-DOME, a department of France, lying between N. Lat. 45. 18. and 46. 16., E. Lon. 2. 27. and 3. 57., bounded on the N. by the department of Allier, E. by that of Loire, S. by those of Haute-Loire and Cantal, and W. by those of Corrèze and Creuse: length, from N.W. to S.E., 85 miles; average breadth, about 50; area, 3002 square miles. The surface is undulating, and has a general slope towards the north, a great part of the area being occupied by the valley of the Allier, which is known by the name of La Limagne. This valley extends from S. to N., and is bounded on either side by lofty branches of the Cevennes, from which smaller valleys descend, each watered by an affluent of the Allier. The western part of the department is mountainous, and contains two volcanic groups called the Monts Dômes and the Monts Dores. The former, which is also called the Chain of Puys, lies more to the north than the other, and reaches its culminating point in the Puy-de-Dôme, which gives its name to the department, and attains the height of 4805 feet above the sea. It has the form of a truncated cone, and has an uneven summit, with no trace of a crater. The whole mountain is covered with green and luxuriant vegetation; and the only traces of volcanic agency are the projecting blocks of lava here and there to be seen. The other summits of this group, about sixty in number, are of the same form and character, and in general have open craters. Of the Monts Dores the highest summit is the Puy de Sancy, 6196 feet above the sea. The slopes of all these mountains, as well as of those of Forez, which bound the Limagne on the E., are exceedingly fertile and beautiful; and the whole valley of the Allier, diversified with isolated hills and slopes, covered with corn-fields, vineyards, and meadows, and studded with towns and villages, presents a most picturesque appearance. The rivers of the department are the Allier, with its affluents, the chief of which are the Dore on the E., and the Sionte on the W. The Dordogne rises in this department, and forms part of its western boundary. The mineral riches of Puy-de-Dôme are very great; antimony, argentiferous lead, iron, coal, marble, granite, basalt, &c., being among its productions. The extent of arable land in the department is about 677,000 acres, of meadow land 165,000 acres, of vineyards 52,000 acres, of wood 151,000 acres, and of waste land 361,000 acres. Although agriculture is in a backward state, from the unwillingness of the people to depart from their old methods, yet the fertility of the soil prevents any deficiency in the quantity of the crops; corn, wine of good quality, potatoes, fruits, hemp, &c., are produced. Cattle are raised in large numbers, as well as horses of a small size, but much esteemed for riding. Silk-worms and bees are also reared. Puy-de-Dôme contains about 13,000 horses, 198,000 horned cattle, 528,000 sheep, 68,000 pigs, and 21,000 goats. Boars, deer, hares, rabbits, foxes, and other wild animals, are found here. Wolves, also, though much diminished in numbers, are still to be met with; and eagles, vultures, &c., haunt the mountainous districts. The forests produce large quantities of timber and firewood, especially pine, oak, and beech. The climate of the department is different in its different parts. In the Limagne the summers are very warm, and the winters short, though sometimes severe; but the higher regions are exposed to cold and inclement weather, often to violent storms. Besides farming, the industry of the people is chiefly employed in the working of mines and quarries. The manufactures of the department are not of much importance; cutlery, nails, paper, woollen cloth, hempen stuffs, &c., are the chief articles produced. A great number of the inhabitants of the mountainous districts leave their homes during the winter season, and travel through France in the pursuit of their several occupations. The principal articles of commerce are agricultural produce, cattle, hides, confectionary, paper, timber, &c. Numerous fairs and markets are held in the department. Puy-de-Dôme forms the diocese of Clermont, and has at that town a Protestant minister and a Jewish rabbin. There is an imperial court at Riom, five tribunals of the first instance, and other courts of law in the department. Its educational establishments include an academy, a lyceum, five colleges, and 508 primary schools. It is divided into five arrondissements as follows:—

	Cantons.	Commnnes.	Pop. (1856).
Claremont-Ferrand	14	108	177,834
Ambert	8	52	86,210
Issoire	9	116	97,670
Riom	13	128	152,323
Thiers	6	39	76,025
Total	50	443	590,062

PUYLAURENS, a town of France, in the department of Tarn, arrondissement and 13 miles S.E. of Lavaur. It has silk-mills, and a considerable trade in horses and mules. Pop. 6095.

PUZZUOLI, or POZZUOLI (anciently *Puteoli*), a town of Naples, in the province and 6 miles W.S.W. of Naples, on the E. side of the Gulf of Puzzuoli. It is slightly fortified, and contains a cathedral and several other churches and convents. It is chiefly interesting on account of the remains of the ancient town which it contains. The harbour is natural and well sheltered; and an active fishery is carried on here. The reddish volcanic gravel found in the vicinity is formed into a fine cement called *pozzolana*, after the name of the town. Pop. 10,000.

PWLLHELI, a sea-port town, municipal and parliamentary borough of Wales, in the county of Cærnarvon, on the N. side of Cardigan Bay, 21 miles S.S.W. of Caernarvon. Its situation is very fine, commanding a view of the whole of Cardigan Bay in one direction, and of Snowdon and other mountains in another. There is one principal street, which is lined with neat and well-built houses. The town contains places of worship belonging to the Church of England, Presbyterians, Independents, Baptists, and Methodists; national and other schools, a poor's-house, and a town-hall. A large number of the people are employed in ship-building; and there is a considerable coasting trade. The harbour is large enough to admit vessels of sixty tons burden. Excellent salmon is caught here; and also oysters, lobsters, crabs, and other shell-fish. Pwllheli unites with Caernarvon, Bangor, Conway, Crickcieth, and Nevin in returning one member to the House of Commons. Pop. (1851) 2331.

PYCNOSTYLE. See *Glossary* to ARCHITECTURE.

PYGMALION, a king of Cyprus, who, being disgusted at the dissolute lives of the women of his island, resolved to live in perpetual celibacy; and making a statue of ivory, he fell so passionately in love with it that he besought Venus to give it life. On his return, he embraced, as usual his ivory form, when he perceived that it became sensible by degrees, and was at last a living maid, who found herself in her lover's arms the moment she saw the light. Venus blessed their union; and he became by her the father of Paphus.

PYLADES, was a son of Strophius, King of Phocis, by one of the sisters of Agamemnon. He was educated together with his cousin Orestes, with whom he formed the most inviolable friendship, and whom he assisted to revenge the murder of Agamemnon, by assassinating Clytemnestra and Ægysthus. He also accompanied him into Taurica Chersonesus; and for his services Orestes rewarded him by giving him his sister Electra in marriage. Pylades had by her two sons, Medon and Strophius. The friendship of Orestes and Pylades became proverbial. (See ORESTES.)

PYLADES, a celebrated pantomimic dancer in the reign of Augustus Cæsar at Rome. (See BALLET.)

PYLUS (*Navarino*), an ancient town of Messina. Originally it seems to have stood at the foot of Mount Ægaleos. In that situation it was probably the "Sandy Pylos" so often mentioned in Homer as the city of Nestor.

Pym.

Thither the venerable patriarch returned after the siege of Troy, and there he was found several years afterwards by the wandering Telemachus, still enjoying a green old age amid a family of valiant and intelligent sons. When the Nestorian capital was destroyed, the name Pylus was transferred to a new city on the neighbouring promontory of Coryphasium. This town in its turn was left to fall into decay and ruin when its inhabitants, at the end of the second Messenian war, emigrated in a body. Pylus then remained desolate and unfrequented until, in 425 B.C., it became the scene of one of the severest checks which Sparta received in the Peloponnesian war. In that year a fort, built on the site of the ruined city, and garrisoned by a small Athenian force under Demosthenes, was unsuccessfully attacked by a body of Lacedæmonians. The assailants found themselves foiled on all hands. On attempting to land in front of the stronghold, they were repulsed. Equally vain was their endeavour to maintain a blockade by settling down on the wild and rugged island of Sphacteria to the south of the fort. In course of time an Athenian fleet arrived, and, taking up its position in the Bay of Pylus, between the island and the mainland, blockaded them in their turn. They were now completely at the mercy of their enemies. In vain did they sue for a truce. Much harder conditions were in store for them. In no long time they were surprised in their strong position by a body of troops under Cleon, and were forced to give up their arms. (See NAVARINO.)

PYM, JOHN, an English patriot and orator, was the son of a Somersetshire squire, and was born at Brymore in 1584. Having prepared for college, he entered Broadgate Hall (now Pembroke College), Oxford, where he equipped himself with all the resources and accomplishments of polite learning. On leaving the university he repaired to one of the inns of court, and stored his mind with the principles and details of common law. It was his good fortune to be appointed to an office in the Exchequer, where he could acquire business tact and financial skill. At length, in 1614, as member for the borough of Colne, he tested his political knowledge and oratorical powers on the great field of parliamentary debate. But it was not until 1620 that Pym began to take an active part in the resistance which the House of Commons was then making to the crooked and arrogant policy of James I. He placed himself by the side of those earnest men who were then forming themselves into a country party. The details of his deeds, it is true, have not been described; but at intervals his name becomes audible, and his form is seen amid the turmoil of the contest. At one time the monarch, balked by the Parliament in his schemes of kingcraft, is heard calling him "a very ill-tempered spirit." Shortly afterwards, he is found in the number of the twelve commissioners, or (as James in a mood of silly sarcasm designated them), "the twal kynges," who went to his majesty at Newmarket with a vindication of the privileges of Parliament. Then he is seen along with Coke, Philips, and Mallory, standing before the council-table, and receiving a sentence of imprisonment in the Tower for his incorrigible opposition to the court. The parliamentary activity of Pym increased after the accession of Charles I. in 1625. The cause of his country then became the task of his life. At all times, and in every place, his vigorous mind was still occupied with the one great object. He studied his speeches late into the night, at his house in Gray's Inn Lane. He explored, in search of precedents, every state-paper in the manuscript collections at Lambeth. He was found in the chair at every religious meeting which the serious-minded politicians of those troublous times convened. There was not an important discussion in the House in which his eloquent tongue was not heard vindicating the liberties of the people against the pusillanimous stratagems of the crown. At the bar of the Lords, too, he sometimes appeared to plead the cases which the Commons had taken up. It was there that he impeached Buckingham, the favourite of the king, for embezzling the public property; it was there that he arraigned Mainwaring, a creature of Laud, for employing all the persuasions and fulminations of the pulpit to advocate despotism. Nor when Charles brought affairs nearer to a crisis, by abandoning the custom of convoking Parliaments, and by governing by prerogative, did he bate one jot of his opposition. He opened a communication with the protesting covenanters of Scotland. He rode with Hampden through several of the counties, instigating the people to petition the coming Parliament. His weapons of eloquence also seem to have been diligently prepared; for on the meeting of the Short Parliament in 1640, he delivered a speech of the length of two hours, which immediately brought the court party to bay, and gave occasion for a speedy dissolution.

Pym.

It was, however, as a member of the Long Parliament that Pym rose to the height of his influence. The title of "King Pym," which was applied to him in ridicule, well describes the authority which he now began to wield. To lead was a duty for which his genius and multifarious acquirements well fitted him. The Parliament had not long commenced before he arraigned the Earl of Strafford at the bar of the House of Lords, on the charge of high treason. The legal evidence was not sufficient; but recourse was had to a bill of attainder. Concluding the impeachment on the 13th of April 1641, he triumphantly proved that the earl's government in Ireland had been subversive of "the fundamental laws" of the kingdom; and he demanded in works of terrific directness and emphasis that sentence of death should be passed upon the prisoner. "Nothing," said he, "can be more equal than that he should perish by the justice of that law which he would have subverted. Neither will this be a new way of blood. There are marks enough to trace this law to the very original of this kingdom; and if it hath not been put in execution, as he allegeth, these 240 years, it was not for want of law, but that all that time hath not bred a man bold enough to commit such crimes as these." Judgment was given in accordance with this demand; and the champion of the popular cause soon proceeded to assail other pliant servants of the king. He again appeared at the bar of the House of Lords to press the impeachment of Laud, on the charge of high treason. Not long afterwards he was the mover of the Grand Remonstrance to the monarch and the people, which, after enumerating a long list of grievances, concluded with the petition that the bishops should be deprived of their votes.

After the civil war had commenced, Pym continued to maintain his prominent position and influence. While the other chiefs of the Parliament were advocating their principles on the field of battle, he was in London ably conducting the executive. With masterly eloquence, he calmed the fears and conciliated the affections of the popular meetings in the Guildhall. With vigorous tact he defeated Waller's plot, and dragged the conspirators forth to punishment.

By this time, however, the continual toils and anxieties of Pym were fast bringing his career to a close. In November 1643 royalist horses were standing constantly saddled and bridled in the stables at London, ready to ride with the news of his death to the king at Oxford. On the 8th of December intelligence was brought to the Commons that their leader had just died at Derby House. They resolved to pay him the last honours with all the marks of esteem which lay in their power. On the 15th of the same month ten of the chief gentlemen among the Commons carried his bier on their shoulders; both Houses of Parliament walked before in mourning; and he was buried "with wonderful pomp and magnificence" in Westminster

Abbey. The nation erected a monument over his tomb, and appointed themselves the guardians of his family.

(See an able and erudite Life of John Pym, containing numerous interesting extracts from his speeches, in Forster's *British Statesmen*, published in Lardner's "Cabinet Cyclopædia.")

PYNAKER, ADAM, an eminent Dutch landscape-painter, was born in 1621 at Pynaker, the village whose name he afterwards assumed. His style was formed during a residence of three years in Italy. Accordingly, on his return to his native land, he painted landscapes very different in character from those of his fellow-countrymen. His favourite subject was a wild mountain scene enlivened by the sheen of a rushing cascade, and softened by silvery birches and other trees. Occasionally there were introduced ruined castles crowning the heights, and solitary herdsmen tending their cattle in the plain below. He was also fond of representing evening scenes on the Tiber. The golden glow of the sunken sun was still lingering on the tops of the trees; barges were sailing down the stream laden with goods and passengers; and flocks were grazing and peasants were sauntering among the luxuriant herbage on the banks. Pynaker had executed about seventy pictures at his death, which took place in 1673.

PYRAMIDS. See EGYPT, § iii.

PYRENEES, a mountain chain in the S.W. of Europe, separating France from Spain, and extending from Cape Creux on the Mediterranean, westwards to the neighbourhood of Fuenterrabia on the Bay of Biscay. It lies between N. Lat. 42. 26. and 43. 23., E. Long. 3. 10. and W. 0. 48. Its length is about 270 miles; and in the centre, where its width is greatest, it has a breadth of 60 miles. It does not consist of a single chain of heights, but of two parallel ranges about 20 miles distant, connected near the centre by a transverse ridge. It is near the middle of the range that the highest elevations occur; from this point it gradually slopes downwards to either extremity. From the central ridge numerous spurs project, both to the north and to the south; between which lie the principal valleys of the Pyrenees. These valleys do not extend, like those of the Alps, in the direction of the principal chain, but at right angles with it; and they terminate in what are called necks (*cols*) or gates (*portes*), where there are frequently passes over the mountains. The length of the valleys varies from 10 to 40 miles, and many of them terminate in vast circular basins called *cirques* or *oules*, surrounded on three sides by steep precipices. The slope of the mountains on the side of France is much more gradual than on the other side. On the former side there are gentle declivities and terraces, which lead down to smooth and verdant meadows; while on the Spanish side the scenery is wild and rugged, and the precipices steep. The principal summits and ridges of the Pyrenees are the following, beginning from the Mediterranean :—

	Height in feet.		Height in feet.
Le Canigon	9,051	Port Viel d'Estaube	8,323
Pic Pedroux	9,511	Port de Pinede	8,122
Col de Puymoren	6,240	Mont Perdu	10,891
Pic du Port de Siguier	9,523	Le Cylindre	10,796
Montcalm	10,663	Port de Gavarnie	7,582
Nethou	11,063	Passage de Tourmalet	7,075
Maladetta	10,764	Vignemale	10,718
Port d'Oo	9,756	Pic du Midi	9,350

The chain of the Pyrenees has very much the appearance of a huge wall between the two countries which it separates, as the ridge has almost everywhere a height little less than that of the lofty summits. The passes of the mountains are at a much greater height than many of those across the Alps, and they are in consequence much less accessible. Although there are as many as seventy or eighty passes in the whole range, many of them are both difficult and dangerous, and there are but few practicable for carriages, such as that of the Bidassoa near the Bay of Biscay, and that of the Col de Pertus along the shore of the Mediterranean. The snow-line of the Pyrenees has an elevation of about 9000 feet on the northern slope, and 8000 on the southern; being considerably below that of the Alps. There are numerous glaciers in these mountains, but they are in general of small size and widely removed from each other. They only occupy the higher slopes of the mountains, and not like those of the Alps the deep glens and valleys. The most important of the glaciers are those of Maladetta, Cabridoul, Mont Perdu, Vignemale, and Neouvielle. The most of the glaciers, as well as of the lakes, which are generally of a small size, lie on the French side of the mountains. Numerous streams take their rise in the Pyrenees, but the most of them are small and insignificant. Each of the valleys is traversed by a brook, called in French *Gave*, in Spanish *Gaba*, and these again unite to form larger rivers. Those on the north side form the Adour, the Ariège, and the Garonne, flowing into the Bay of Biscay; and the Aude, Gly, Tet, and Tech, into the Mediterranean. Those on the Spanish side, with the exception of the Bidassoa, which falls into the Atlantic, and a few small streams into the Mediterranean, join the Ebro on its left bank. There are many mineral springs, both cold and hot, especially on the French side of the mountains. The principal of these, which are much frequented by visitors, are Bagnères de Luchon, Bagnères de Bigorre, Barège, Cauterets, St Sauveur, Eaux Bonnes, and Eaux Chaudes. In geological formation, the nucleus of the mountains is granitic, and the highest summits of the chain are of this nature. Micaceous schist, limestone, sandstone, oolite, and calcareous strata also occur on the lower slopes; and trap, basalt, porphyry, &c., are scattered about in different places. Iron, copper, zinc, and lead are among the mineral riches of the Pyrenees; but iron is the only one of these that has been profitably worked. The climate of the mountains varies considerably in different parts: towards either extremity the lower elevation of the range, and the vicinity of the sea, renders it more mild than it is in the centre. Vegetation ascends to a higher altitude here than in the Alps; and the immense forests which cover the sides and sometimes the tops of the mountains, not only of firs, but of oaks and beeches, form one of the most characteristic and beautiful features of the Pyrenees. The timber has, however, suffered much from the carelessness and waste of the people of the country. These vast forests are filled with wild animals of many different kinds, the bear, the boar, the wolf, the lynx, and the fox, being among the number. The izard, an animal like the chamois, but of smaller size, and the wild goat, form a great attraction for the sportsman. The rivers abound in trout, and those that flow into the Atlantic in salmon. The inhabitants of the Pyrenees include several races that are remarkable for their antiquity or peculiarities of dress and manners. At the western extremity, partly in France and partly in Spain, dwell the Basques, the descendants of the ancient Cantabrians, who so stubbornly resisted the Roman arms, and have since kept their position in these mountain fastnesses against all invaders. Further east, on the French side, are the simple and primitive people of Béarn, from among whom Henri IV. sprung; and in the eastern part of the mountains the inhabitants of the French side have much resemblance to the Catalans of Spain. The people on the Spanish side of the Pyrenees are a bold hardy race, living by smuggling and the chase, with an invincible hatred to the French, and forming excellent guerilla soldiers, as has often been proved. The Pyrenees have been the scene of several important historical events. Hannibal crossed them by the Col de Pertus, just before his more celebrated passage of the Alps; and Cæsar afterwards did so at the same place. In 778, Charlemagne, advancing into Spain, crossed by the Pass of Roncesvalles, where he suffered a defeat and lost many of his peers at the hands of the Basque mountaineers. The same pass was again surmounted by an English army under the Black Prince, invading Navarre; and in 1813, after the victory of Vittoria, the British army under Wellington drove the French across the Pyrenees into their own country. It was on this occasion that the battle of Roncesvalles, the assault and capture of St Sebastian, the passage of the Bidassoa and of the Nivelle, and other actions, took place.

Pyrénées, *Basses*, a department of France, in the south-western corner of the country, lying between N. Lat. 42. 47. and 43. 35., E. Long. 0. 2. and W. 1. 45.; bounded on the N. by the department of Landes, E. by those of Gers and Hautes-Pyrénées, S. and S.W. by Spain, and N.W. by the Bay of Biscay: length, from E. to W., 88 miles; greatest breadth, 54; area, 2900 square miles. It lies in the lower slopes and at the foot of the Pyrenees, from which it derives its name; and a part of its surface is occupied by the offsets and valleys which extend northwards from these mountains. The department is watered by the streams which rise in the Pyrenees, and flow down these valleys; most of them, except the Nivelle, and the Bidassoa which rises in Spain, and forms the frontier between the two countries, flow into the Adour. This river, which only washes the department at its N.E. corner, and again at the N.W. near its mouth, receives, among other affluents from Basses-Pyrénées, the Gave de Pau, the Gave d'Oloron, and the Nive. Of these rivers, the Adour, Nive, and Nivelle, are navigable for some distance above their mouths; but all are employed for floating down timber and other articles almost from their very sources. Though the soil is in general not very remarkable for fertility, the lower valleys are richly productive, and the loftier slopes and mountains, besides their vast and valuable forests, afford excellent pasturage. The hillsides are covered with excellent vineyards, and with plantations of fruit trees. There are, however, some tracts of barren or marshy ground, especially in the N.W. and near the Adour. The climate of the lower regions is temperate and healthy, though very variable; but in the more elevated parts the *goître* is not unfrequent. The department is calculated to contain 386,072 acres of arable land, 321,671 acres of wood, 57,266 of vineyards, 163,720 of meadows, and 841,995 of heaths and waste land. Agriculture is in a very backward state, and the produce of corn is not at all adequate to supply the wants of the people. Besides maize, which forms a principal article of food here, wheat and flax are the chief crops raised; while rye, barley, and millet are also grown. The quantity of wine produced in the department is upwards of 6,500,000 gallons annually. Horses, mules, and cattle are raised here in considerable numbers, as well as sheep and pigs; the latter of which supply the much-esteemed hams of Pau and Bayonne. The mineral riches of the country are very great, including iron, salt, marble, alabaster, slate, limestone, and potter's clay, which are worked to some extent. Manufactures have made considerable progress in the country, especially those of linen and woollen stuffs; as well as leather, paper, pottery, hardware, chocolate, and brandy. Ship-building is carried on along the coast, the timber of the forests being excellent for that purpose. The commerce is very active; horses, cattle, hams, hides, wool, wines, brandy, timber, and other produce of the country are exported; while colonial wares, whale and seal oil, &c., are imported. A great deal of trade, chiefly contraband, is carried on with Spain. The department forms the diocese of Bayonne; and besides the places of worship of the established church, contains a Calvanistic church at Orthez, and several Jewish synagogues. There is at Pau a court of appeal for the three departments of Landes, Hautes, and Basses-Pyrénées; five tribunals of the first instance, and two of commerce, being the other courts of justice in the department. For educational purposes there are a normal school, a college, a lyceum, six superior communal schools, and 914 elementary schools. The capital is Pau, and there are five arrondissements as follows:—

	Cantons.	Communes.	Pop. (1856).
Pau	11	185	127,771
Oloron	8	80	73,675
Orthez	7	135	78,929
Bayonne	8	52	86,996
Mauléon	6	108	69,071
Total	40	560	436,442

Pyrénées, *Hautes*, a department of France, lying between N. Lat. 42. 39. and 43. 34., E. Long. 0. 30. and W. 0. 20.; bounded on the W. by the department of Basses-Pyrénées, N. by that of Gers, E. by that of Haute-Garonne, and S. by Spain: length, from N. to S., 48 miles; greatest breadth, 45; area, 1790 square miles. The surface is very mountainous, being almost entirely occupied with the Pyrenees and their branches. In many of the glens and valleys the scenery is of the most sublime and beautiful character. The country slopes gradually towards the north; and a chain of hills running in the same direction separates between the valley of the Adour on the W. and of the Garonne on the E. These rivers receive all the numerous brooks which flow down from the mountains; the chief affluents of Adour being the Gave de Pau, which waters the south-west of the department, and the Arros, which flows northward, and joins it from the E. The Garonne, rising in the valley of Arau, which belongs to Spain, receives from this department the Neste in the south-east, the Gers, and the Baise, which water its north-eastern portion. The principal plain in the Hautes-Pyrénées is that of Bigorre, which lies between two branches of the Pyrenees, and slopes gradually towards the north. With the exception of this plain, there is very little good soil, from the rugged and mountainous character of the country. The pasture grounds, however, are good, and the forests valuable. The extent of arable land is estimated at 235,000 acres; of meadow land, 123,000 acres; of vineyards, 37,000 acres; of wood, 200,000 acres; of waste land, not less than 395,000 acres. The principal crops are maize and wheat, but the quantity produced is insufficient for domestic consumption; of the wine grown, however, there is a surplus for exportation. The climate varies with the varying elevation of the country; but it is on the whole salubrious. On the plain of Bigorre it is mild; but in the higher regions changeable and inclement weather prevails. Besides agriculture, the peasantry are actively employed in pastoral pursuits. Large numbers of horses, which are much valued for cavalry, as well as horned cattle, mules for export into Spain, sheep and pigs, are raised here. Much attention is also paid to poultry, especially geese, and to bees. The mineral wealth of the department is great, including iron, copper, zinc, lead, &c.; but these are only worked to a small extent. Granite, marble, chalk, limestone, and slate, are quarried. Manufacturing industry is not very active here. It consists chiefly in the working of iron, and producing woollen and cotton fabrics, the stuffs called *barège* (from the town of that name), paper, and leather. There is a considerable trade in timber for ship-building, cattle, salt provisions, cheese, &c. Hautes-Pyrénées forms the diocese of Tarbes, and contains three courts of the first instance, 4 colleges, 4 upper schools, and 768 elementary schools. The capital is Tarbes; and there are three arrondissements as follows:—

	Cantons.	Communes.	Pop. (1856).
Tarbes	11	195	111,997
Argelès	5	91	41,682

PYRÉNÉES-ORIENTALES, a department of France, lying between 42. 20. and 42. 55. N. Lat., 1. 44. and 3. 10. E. Long., bounded on the W. and N. by the departments of Ariège and Aude, E. by the Mediterranean, and S. by Spain: length, from E. to W., 75 miles; greatest breadth, 35; area, 1585 square miles. Though the greater part of the surface is occupied by mountains, yet there is a wide plain stretching along the shore of the Mediterranean. In the interior there are two nearly parallel chains of hills which run from E. to W., and divide the country into three long valleys, watered by the Gly, the Tech, and the Tet respectively. These rivers, none of which is navigable, fall into the Mediterranean, and water the greater part of the country; while the Aude, which rises in the east of this department, flows northward through the department to which it gives its name, and it too falls into the Mediterranean. The natural fertility of the soil is by no means great, and a large portion of it is unfit for cultivation; but the plain along the sea-shore is so well watered by a system of irrigation from the rivers that traverse it as to produce a supply of corn more than enough to meet all domestic wants. In the western portion of the department, which is very hilly, vines thrive well on the high ground, while the valleys are little inferior to the eastern plain; and even along the southern frontier, rye, oats, maize, pulse, &c., may be grown, where neither wheat nor the vine could flourish. The department contains about 346,000 acres of arable land, and 395,000 of heaths and waste land, the rest being occupied with forests, vineyards, &c. The annual produce of wines is about 8,800,000 gallons, and more than a third of this quantity is exported. The wines of Collioure, Port-Vendres, Rivesaltes, &c., which come from this country, are very highly esteemed. The extent of the pasture-grounds enable the people to keep large numbers of live stock,—horses, mules, horned cattle, sheep, and goats. Like the other Pyrenean departments, this region contains many valuable minerals. There are numerous iron mines here, as well as smelting-houses and forges for the metal. Coal, marble, alabaster, granite, and sulphur are also worked. The manufactures of Pyrénées-Orientales include those of leather, broad cloth, hosiery, corks, brandy, pottery, and bricks, besides those connected with the production of wine and iron. The fisheries of tunny, anchovies, sardines, &c., along the coast are very productive; and there is an active coasting trade. The exports considerably exceed the imports in value; and consist of wine, brandy, cattle, salt provisions, linen and woollen stuffs, iron, and marble. The department forms the diocese of Perpignan, and contains three courts of the first instance and one of commerce. For the purposes of education it has a college, a normal school, a superior communal school, and 313 elementary schools. It is divided into three arrondissements as follows, and the capital is Perpignan:—

	Cantons.	Communes.	Pop. (1856).
Perpignan	7	85	90,099
Céret	4	42	42,181

PYRITES. See CHEMISTRY, §§ *Iron*, and *Copper*.

PYRITZ, a town of Prussia, in the province of Pomerania and government of Stettin, in a fertile plain 24 miles S.E. of Stettin. It is surrounded by walls, with five lofty towers, now the only remains of its ancient fortifications, and entered by three gates decorated with antique ornaments. There are here a town-hall, churches, schools, and hospitals, as well as manufactures of leather and cloth. Not far off is a fountain where the earliest converts to Christianity in Pomerania, 7000 in number, were baptized by Otto of Bamberg in 1124. A monument was erected here in 1824 to commemorate the event. Pop. 5807.

PYROMETER.

PYROMETER (from πῦρ, *fire*, and μέτρον, *a measure*), an instrument for estimating high degrees of temperature, such as the heat of furnaces and the fusing-points of many of the metals. The scale of a common thermometer is graduated on the supposition that equal increments of heat produce equal amounts of expansion; but this is only true within moderate ranges of temperature; for as we increase the heat, most fluids leap forward, as it were, to meet their boiling points, and cease to be trustworthy as measurers of temperature. Thus, according to Regnault, the total expansion of mercury for three progressive intervals of 180° Fahr. is as follows:—Between 32° and 212° it is 1 part in 55·08 parts; between 212° and 392° it is 1 in 54·61; and between 392° and 572° it is 1 in 54·01. Thus, at various times, instruments have been contrived for measuring temperatures above the boiling-point of mercury (662° Fahr.), the term *pyrometer* having been first used by Muschenbroek about the year 1730. His instrument consisted of a metallic bar, about six inches long, one end of which was fixed, while the other was free to move as the metal increased in length, from the effect of a number of spirit-lamps placed beneath it, and charged with a known quantity of highly-rectified spirits of wine. As the bar increased in length, it moved a pinion and wheel, and the latter moved an index over a graduated circle, each degree of which corresponded to a linear expansion of $\frac{1}{12500}$ths of an inch. The instrument was improved by Desaguliers, who substituted fine cords and friction rollers for the wheel and pinion. Pyrometers were also contrived by Ellicott, Graham, Smeaton, Ferguson, and others. These do not differ from Muschenbroek's instrument, in which the minute expansion of a bar of metal is multiplied by means of a succession of levers, or a system of wheels and pulleys, a method which must be very liable to error, in consequence of the bending of the parts, obliquity of action, and other causes. Besides this, the substance itself, if liable to be softened by heat, would undergo compression in moving the machinery, an objection which, to a certain extent, applies to the more refined apparatus employed by Lavoisier and Laplace, in which the expansion of the metal bar deflected a telescope from the position that it had at the beginning of the experiment, and the absolute expansion was deduced from the extent of this deflection, which was read off upon a graduated scale placed at a considerable distance in front of the telescope. In 1794 Troughton contrived an apparatus somewhat similar; only, instead of a telescope, he used a spirit-level, the deviations of which from the horizontal determined the expansion of the metal.

Pouillet's method may also be referred to for measuring directly the linear expansion of solids, and it has the advantage of being applicable to very high temperatures. It consists of a solid plate of metal, on which is placed a radius turning on a centre, and traversing a graduated arc, the divisions of which are read off by a microscope. The radius carries a telescope of short focus, fixed at right angles to its direction, while a similar telescope is fixed to the plate itself, allowing the radius to traverse under it. The bar which is the subject of experiment is placed in a copper trough furnished with parallel plates of glass, through which its ends can be seen. Now, if one extremity of the bar be kept opposite the fixed telescope, while the moveable telescope is directed to the other extremity at the commencement of the observation, any expansion of the bar caused by raising its temperature may be estimated by the arc through which the radius must be turned, in order to bring the moveable telescope to bear on the other extremity in its new position, the distance of the radius from the bar being accurately known. For very high temperatures, the bar may be placed in a furnace, and when raised to the required temperature, apertures may be opened in the furnace walls, so as to give a view of the ends of the bar, and allow its expansion to be measured as before. By means of this apparatus an expansion in the bar of $\frac{1}{1980}$th of a millimetre, or about $\frac{1}{50000}$th of an inch, can be appreciated.

In the measurement of the base-line for the great French survey, Borda used rods consisting of a rule of brass placed upon a somewhat longer rule of platinum, and attached at one extremity. The portion of the platinum rule not covered by the brass one was divided into millionths of the entire length of the rule, and further subdivided by means of a vernier and microscope adjusted to the extremity of the brass rule. The value of each of these divisions was first ascertained by surrounding the compound rule with melting ice, and afterwards with boiling water, when it was only required to observe the indications of the vernier to apply the requisite correction for reducing the length of the rod to the standard temperature. Ramsden's contrivance, used by General Roy in determining the expansion of the rods employed in measuring the base-line on Hounslow Heath was as follows:—The rod was immersed in water, and over each extremity was placed a microscope, to which a slow motion could be given in the direction of the length of the bar by means of a micrometer-screw. The lines of collimation of the microscopes having been adjusted so as to coincide with two points near the ends of the rod, the temperature of the water was gradually raised any required number of degrees, as indicated by a thermometer, when the elongation of the rod destroyed the coincidence of its extremities with the lines of collimation of the microscopes, which was re-established by turning the micrometer-screws, and noting the number of turns and fractions of a turn required for the purpose. In this way a direct measure of the expansion was obtained, free from the errors of levers, wheels, and pinions.

In the measurement of the base-line of Loch Foyle for the ordnance survey of Ireland, General Colby employed a compound bar of iron and brass, so arranged that their different powers of expansion and contraction should preserve exactly the same distance between two points at the extremities of the bars, instead of the usual method of allowing for the change in length according to the temperature at which each rod was laid. The two bars, one of iron, the other of brass, each ten feet long, were placed parallel to each other, and riveted together at their centres, and coated with a non-conducting substance, to equalize the susceptibility of the two metals to change of temperature. It was ascertained, by numerous experiments, that the iron and the brass bars expanded and contracted, in their transitions from cold to heat and from heat to cold, in the proportion of 3 to 5. Across each extremity, therefore, of these combined bars was fixed a tongue of iron, with a minute dot of platinum, so situated that under every degree of expansion and contraction of the rods the dots at each end always remained at the constant distance of 10 feet.

In the *Philosophical Transactions* for 1782, 1784, and 1786, is a description of Wedgwood's pyrometer. This was based upon the property possessed by clay to contract and harden by exposure to a high temperature, the clay, under such circumstances, losing a portion of its combined water, exactly proportioned, as it was thought, to the intensity of the heat. The clay was punched out into small cylinders, with one side flattened, and having been exposed to the temperature which it was desired to measure, the amount of the contraction was determined by sliding the cylinders along a metallic groove or gauge, the sides of which gradually converged until they arrived at a point beyond which they would not descend. The gauge was divided into 240 parts or degrees, each of which was calculated to be equal to 130° Fahr., while the zero of the scale, indicating a red heat, corresponded, according to Wedgwood's experiments, to 1077°. The difficulty of obtaining clay of uniform composition is one objection to this method of measuring high temperatures; different kinds of clay afford very different results, as does also the same kind of clay prepared with a little more or less of mechanical force; but the most fatal objection is, that clay will contract as much by the long continuance of a comparatively low heat as by the short continuance of a high one. This accounts for the enormous exaggeration of Wedgwood's degrees, and the disuse into which the instrument has fallen.

Achard contrived a pyrometer in the form of the common thermometer, consisting of a bulb and graduated tube of semi-transparent porcelain highly baked, and containing a fusible alloy of bismuth, lead, and tin, which liquefied at about 212°, and by its expansion noted higher temperatures, the semi-transparent material allowing the rise of the metal to be seen.

The method contrived by Messrs Dulong and Petit for measuring the absolute expansions of different substances deserves notice. By observing the difference in height at which mercury stood in the two limbs of a U tube, when of different temperatures, they obtained the absolute expansion of the mercury, and by comparing this with the apparent expansion of mercury in a glass tube, they deduced the absolute expansion of the glass. When the expansion of a metal was to be estimated, a cylinder of it was put into a glass tube, closed at one end, and drawn to a capillary opening at the other, while the rest of the tube was filled with mercury. On heating the tube, a portion of the mercury was expelled, equal to the excess of the absolute expansions of the mercury and the metal above that of the glass; and as the expansions of the mercury and of the glass had already been determined, the weight of the mercury expelled determined the expansion of the metal.

In 1803 M. Guyton de Morveau submitted to the National Institute a pyrometer, consisting of a bar of platinum, about 2 inches long, placed in a porcelain groove, one end resting against the solid end of the groove, while the other, pressed upon the short arm of a lever, the longer arm of which moved a vernier over a graduated circular arc. The indications of the vernier at the beginning and end of an experiment furnished the means for determining an expansion. This instrument, however, was not applied to the determining of higher temperatures than that of the melting point of antimony, in consequence of the softening which platinum undergoes at a red heat.

In the *Philosophical Transactions* for 1830 is a description of Professor Daniell's pyrometer, which deserves special notice, as being the first instrument constructed for determining high temperatures with anything like accuracy. It consists of two parts, the *register* and the *scale:* the register is a solid bar of black-lead earthenware highly baked; in this is drilled a hole, into which a bar of any metal 6 inches long may be dropped, so as to rest upon its solid end. A cylindrical piece of porcelain, called the *index*, is next placed on the top of the bar, and confined in its place by a ring or strap of platinum passing round the top of the register, which is partially cut away at the top for the reception of a wedge of porcelain. When this arrangement is exposed to a high temperature, the expansion of the metallic bar forces the index forwards to the amount of the excess of its expansion over that of the black lead, and on cooling, the index will be left at the point of greatest elongation. It is the function of the scale to measure the distance which the index has been thrust forward from its first position. The scale, which is independent of the register, consists of two rules of brass joined together at a right angle by their edges, and fitting square upon two sides of the black-lead bar. At one end of this double rule projects at a right angle a small plate of brass, which may be brought down upon the shoulder of the register, which is formed by the notch cut away for the reception of the index. Attached to this frame is a moveable arm turning near one end upon a centre, and carrying at its other end an arc of a circle, the radius of which is 5 inches, and divided into degrees and thirds of a degree. Upon this arc, at the centre of the circle, turns another lighter arm, to the further end of which is attached a vernier moving upon the face of the arc, and subdividing it into minutes of a degree: the other end passes beyond the centre, and terminates in a steel point turned inwards at a right angle.

The various parts of the instrument are represented in figs. 1 and 2. Fig. 1 represents the register, in which A is the bar of black lead, *aa'* the cavity for the reception of the metal bar, *cc'* is the porcelain index, *d* the platinum band, with its wedge *e*. Fig. 2 represents the scale by which the expansion is measured, *ff'* is the greater rule upon which the smaller one *g* is fixed square. The projecting arm *h* is also fitted square to the ledge under the platinum band *d*. D is the arm which carries the graduated arc attached to the rule *ff'*, moving on the centre *i*. C is the lighter bar moving on the centre *k*; H is the vernier, *m* the steel point. The rule *g* can be adjusted upon *ff'*, so that the arm *h* may be adjusted to the centre *i*, in order that at the commencement of an experiment the vernier may rest at the beginning of the scale.

Fig. 1.

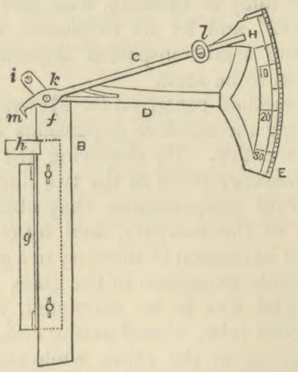

Fig. 2.

When an observation is to be made, the metallic bar is placed in the cavity of the register at the ordinary temperature; the porcelain index is pressed down upon it, and firmly fixed in its place by means of the platinum strap and the porcelain wedge. The scale is then applied by carefully adjusting the brass rule to the sides of the register, and fixing it by pressing the cross piece upon the shoulder, and placing the moveable arm so that the steel point of the radius may drop into a small cavity made for its reception, and coinciding with the axis of the metallic bar. The minute of the degree which the vernier indicates upon the arc must be noted; the scale is then removed, and the register exposed to the temperature which is to be measured. After it has been withdrawn and allowed to cool, the porcelain index retains the position corresponding to the maximum temperature of the rod; the scale being now again applied to the register in exactly the same position as before, the arc through which the radius must be moved to bring the point in the arm of the lever to bear against the index, measures the quantity by which the latter has been protruded. This quantity is the excess of the expansion of the metal rod over the black-lead envelope, or rather that excess diminished by the contraction of the index in cooling. The scale of this pyrometer is connected with that of the thermometer by observing the amount of expansion between two fixed points, such as the freezing of water and the boiling of mercury. The amount of expansion for a known number of degrees is thus determined, and the value of all other expansions may be considered as proportional. By means of this instrument, the melting-point of cast-iron has been ascertained to be 2786°, and the highest temperature of a good wind-furnace about 3300°, points which were estimated by Wedgwood at 20,577° and 32,277° respectively.[1]

M. Breguet has a pyrometer consisting of a compound ribbon of three metals, platinum, gold, and silver, rolled out into a very thin lamina, and coiled into a cylindrical spiral, to the lower extremity of which is attached an index, while the upper end of the spiral is fixed. The silver expands much more than the platinum, so that the coil twists and untwists as the temperature rises and falls. The degrees on this instrument are marked upon a horizontal circle, and their value is found by comparison with a standard thermometer.

In the *Philosophical Transactions* for 1828, Mr Prinsep describes a method of measuring high temperatures based upon the fixed value of the fusing-points of pure metals. The noble metals alone embrace a range from the low melting-point of silver to the very high one of platinum, and although there may be only three fixed points in the scale thus furnished, intermediate links may be supplied by alloying the three noble metals together in different proportions. When such a series has been prepared, the heat of a furnace may be expressed by the alloy of least fusibility which it is capable of melting. As the melting-points of silver and of gold are comparatively near to each other, ten intermediate gradations were assumed, the lowest of which corresponded to the fusing-point of pure silver, and the others to the fusing-points of silver alloyed with 10, 20, 30, &c., per cent. of gold. From the melting-point of gold to that of platinum 100 gradations were assumed, which were the melting-points of pure gold, and of gold alloyed with 1, 2, 3, &c., per cent. of platinum. The only apparatus required for this method is a small cupel, containing in separate cells 8 or 10 pyrometric alloys, each about as large as a pin's head, and when the specimens had been once used, they could be used again by simply flattening them under a hammer. The notation is equally simple, since two letters and the decimal of alloy would express the maximum heat; thus S . 3 G gives the temperature of the fusing-point of silver when alloyed with gold in the proportion of 7 to 3, and G . 23 P expresses the fusing point of gold when alloyed with platinum in the proportion of 77 to 23. Mr Prinsep endeavoured to connect the fusing-points of his alloys with the thermometric scale by employing the expansion of air on the principle of the differential thermometer, assuming that the increase of temperature is proportional to the expansion of the air, which, however, is not the case.

---

[1] An able article on pyrometers contained in the *Penny Cyclopædia* has a mathematical investigation of the correct formula to be used with Professor Daniell's instrument, and shows that the formula employed by him, "though probably sufficiently correct for all practical purposes, gives the expansions one per cent. too great without exception, and in many cases much more. . . . The error thus introduced is perhaps within the limits of the error to which the instrument itself is liable."

A trial of Mr Prinsep's method was made some years ago at Sèvres for the purpose of determining the temperatures of the ovens used for baking porcelain. It was found necessary to expel silver from the short list of available metals, on account of the peculiar property possessed by this metal of absorbing oxygen during its fusion, and *spitting* it out again during the cooling. The small tubes or globules of the melted metal, which are forcibly expelled by the escaping oxygen, are more fusible than the principal alloy, and disturb its fusing-point. The presence of 1 or 2 per cent. of copper might have neutralized this property if it did not interfere with the other results. The experiments were therefore limited to the alloys of platinum and gold in various proportions. It was found, however, to be very difficult to determine in a close furnace the exact moment when the alloys fused; moreover, it was found that similar alloys did not always melt at the same moment, although apparently placed under precisely the same circumstances. It was also found impossible to use the same bead of alloy more than once, the action of the fire effecting some molecular change which led to an alteration in the fusing-point; still, however, M. Laurent (whose results were subsequently confirmed by M. Salvétat) was able to determine that the highest temperature attained in the kiln at Sèvres was represented by the alloy $\left.\begin{matrix}P\ .\ 53\\ G\ .\ 47\end{matrix}\right\}100$, when a well-fused button was formed, while, with 54 parts platinum, there was only a softening perceived. M. Brongniart remarks on this result,—"When we succeed in being able to determine exactly and promptly the moment when complete fusion takes place in these alloys, we shall have comparable measures of high temperatures, but not a method fit to be employed habitually in industrial operations, in which it is not required to know the temperature in one single spot, or at the end of an operation, but in various places and at various times in order to manage the fire as equably as possible, and to arrest it at the proper moment.[1]

A good pyrometer is still a desideratum in the useful arts for regulating the heat of furnaces, &c. It should be easy of application in the hands of common workmen, prompt in its results, exact in its indications, so as not only to serve as a guide to the particular process in hand, but to give information to manufacturers in all places and at all times of the temperature required for the successful conducting of a particular process. The unalterable nature of platinum would seem to point out this metal as a desirable pyrometer, especially since it is more equable in its expansion than any of the other metals, but is not free from that increasing rate of expansion with increasing temperatures which belongs to most substances. The small amount of dilatation of platinum is an objection to its use, especially when that dilatation has to be communicated to a distance through rods of various kinds which act upon the measuring apparatus, all of which are liable to error. Herr Wurm has endeavoured to employ platinum in the form of a moderately strong wire stretched across a strong massive frame of iron, furnished with a handle; the wire is kept in a state of tension by a spring or otherwise, and when it becomes relaxed by expansion, an index in the handle connected with it shifts and marks the amount of extension. When it is required to ascertain the temperature of a furnace or oven, the whole frame is introduced into it, the wire instantly acquires the temperature of the furnace, but the massive frame does so slowly; relative expansion of the wire, therefore, takes place, and when this has attained its maximum, the index is read off.

As long since as the year 1805 M. Brongniart constructed a pyrometer for measuring the comparatively moderate heat of the gloss oven or muffle furnace (see Pottery and Porcelain) by means of the dilatation of a bar of silver. The advantages of this metal are stated to be its resistance to the highest temperature of the muffle furnace, the facility with which it may be obtained pure, so that the results of two instruments will be comparable; it resists an incandescent heat, and is more dilatable than any other metal possessing all these advantages. The only inconvenience accompanying its use is the impossibility of applying it to measure higher temperatures. The bar of silver is two decimetres in length; it is placed in the muffle in the midst of the articles which are being fired, and is inserted through one of the sight-holes used for watching the progress of the vitrification; its dilatation serves to note the rise of temperature and the point at which the heat ought to be arrested. In order to measure this dilatation, the bar is placed in a groove of hard porcelain, one end of which is turned up to serve as a fulcrum to the inserted end of the bar. The near end of the bar presses against a porcelain rod which gives motion to a needle over a graduated arc, so graduated as to multiply a hundred-fold the dilatation of the bar of silver. This arc is divided into 300 parts; from 27° to 30° of this arc are about equivalent to 100° of the centigrade thermometer. The firing of the colours upon porcelain varies from 200° to 280°C. Silver fuses between 300° and 325° of this pyrometer, so that the maximum heat for vitrifiable colours is not far short of the fusing-point of silver. M. Brongniart modestly remarks that this instrument is imperfect, since it does not register absolute measures of temperature, but only the difference between the dilatation of a bar of silver two decimetres long, and that of a bar of hard porcelain of the same length. The dilatation of the porcelain at this temperature is not known, except that it is very small; we have therefore only the difference between two quantities, of which one only has been ascertained.

In the year 1835 Mr Adie of Edinburgh read a paper before the Royal Society of Edinburgh (*Trans.* xiii.) on the expansion of different kinds of stone. His pyrometer consisted of a vertical metal cylinder about 2 inches in diameter, and about 27 or 28 inches long, for containing the stone rod which was to be measured. The cylinder was surrounded by a steam jacket, through which was passed a current of steam for the purpose of raising the temperature of the cylinder and the rod. The case contained windows of plate glass, through which both ends of the rod could be seen; the lower end rested on a support which could be adjusted in height by means of a screw passing through the bottom of the cylinder, and steadied against the sides by means of springs and friction-rollers. Two silver studs were fixed in each rod that was to be operated on, at the exact distance of 23 inches, at the ordinary temperature. The cylinder and case were attached to a vertical oaken beam, to which were fixed two microscopes, with their axes horizontally directed to the studs. The lower miscroscope kept the lower stud stationary in view, while the upper one measured the expansion of the bar by means of a micrometer. The oaken beam was screened from the radiation of the heat of the steam jacket, and the current of steam was maintained therein until the rod ceased to increase in length, when its expansion was measured. The rods were generally raised to about 207° or 208° Fahr., and about four hours were required to raise a rod from 50° to this temperature, the section of the rods varying from a square half-inch to an inch. From the amount of expansion for the observed changes of temperature, a table of expansions for 180° Fahr. was calculated. All the stones operated on contained moisture, the effect of which, in the case of greenstone and some marbles, was to increase the amount of expansion; in other instances no such effect was observed. In white Sicilian marble a permanent increase in length was produced every time its temperature was raised, the amount of increase diminishing each time.

---

[1] *Traité des Arts Céramiques*, i. 235.

In the Great Exhibition of 1851 Mr Ericsson exhibited in the United States department a pyrometer for measuring temperatures from the freezing-point of water to the melting-point of iron, as indicated by the tension of a permanent volume of air or of nitrogen gas, which is measured by the reading of a column of mercury under a vacuum. The instrument is intended for the regulation of processes in the useful arts in which great heat is required, and an evenly-regulated temperature is of importance. In the formation of the scale, 32° and 212° have been taken for the points of freezing and of boiling water. The instrument consists of a chamber containing mercury, with a flexible bottom composed of a steel spring, or of india-rubber held between steel plates, and capable of being raised or lowered by means of a screw. Into this chamber a glass tube filled with mercury is plunged to within $\frac{1}{16}$th of an inch of the base. Into the mercurial cistern is inserted a short glass tube connected with a platinum bulb by a small passage, the base of which is nearly filled by a silver wire and a stop-cock. A coupling-joint is affixed to the bulb, so that it may be removed at pleasure. The top and sides of the mercurial chamber are surrounded by a cistern for the reception of pounded ice; the whole being encircled by double plates of iron to be filled with clay or some other badly-conducting substance, for the purpose of shielding and supporting the instrument. The screen itself is supported upon a base-plate. Two scales are graduated for reading off the height of the mercury in the tube, as determined by the temperature of the medium in the platinum bulb. The graduation of the smaller of these scales extends only to 700°, but that of the larger includes the melting-point of iron. There is also a spirit-level for placing the instrument in a vertical position. The graduation of the scale is independent of any imperfection in the bore of the tube, and is not affected by the expansion of the bore from heat, the volume for measuring which, being permanent and not expanding, affords greater accuracy in the readings at high temperatures. The pyrometer comes into action when the thermometer ceases to be effective; the air or nitrogen in the bulb of the former allowing it to remain unchanged under extreme variations of temperature, whilst the latter explodes on being thrust into an ordinary flue or vessel of over-heated lead. The Jury Report from which this description is abstracted, offers no opinion as to the value of the instrument, nor does it appear that the jury tested its value by experiment. (C. T.)

PYROTECHNY

PYROTECHNY (from πυρ, *fire*, and τέχνη, *art*). The usual modern meaning of the word is the art of making fireworks, and of disposing them to the best advantage when exhibited on occasions of rejoicing, or in theatres, gardens, and other places. A moment's consideration will show how very comprehensive a term *pyrotechny* may become if extended to all operations in which the skilful management of fire is required. It was anciently confined chiefly to alchemy, or incipient chemistry.[1]

Under the term of pyrotechny we may properly enough include the making of the different sorts of gunpowder, and the preparation of all those combustible or detonating materials and projectiles used in war; but then it should be distinguished by the adjunct *military*. Military pyrotechny will then serve only to indicate a portion of one of the most deplorable arts ever invented,—that is, the art of war. The miserable necessity of this art is, however, a matter of daily experience in the present state of human nature and unsocial relations; also the unhappy and slavish condition of all nations which are not able, by skill in this diabolical art, to resist effectually the aggressions of their invaders.[2]

We do not mean to give an account of the various substances, mixtures, and manipulations necessary in the construction of different fireworks; but, for the reader's amusement and instruction, we shall mention a few things which are not generally known, and then conclude with the titles of a few works upon pyrotechny.

The combinations of the different substances employed in the pyrotechny connected with fireworks ought to be guided by a chemical knowledge of these substances. The want of this knowledge causes most of our fireworkers to compound ineffective mixtures, and to follow old and absurd recipes. Great skill in pyrotechny, in its more general sense, was possessed by the Chinese long before the art was known in Europe. The invention of gunpowder seems to be due to them, and perhaps also the invention of fireworks. All those persons we ever conversed with who had been in China concurred in assuring us that the Chinese fire-works are at this day quite unrivalled in variety, splendour, and beauty. In the account of Lord Macartney's embassy to China there is an amusing passage describing the contempt of the Chinese for the best English fireworks that were exhibited to them, and the astonishment of the embassy on witnessing the superb display of fireworks given by the Chinese in return. The most imposing exhibitions of European fireworks used to be those that took place annually at Rome, during certain holidays, on the ramparts of the Castle of St Angelo.

We shall now give a very few notices of practical pyrotechny.

Lightning.—The fine seeds of the *Lycopodium clavatum*, or common club-moss, are extremely inflammable, and are used in theatres to imitate a vivid flash of lightning, by blowing them from a tube, &c., through the flame of a lamp, &c. These seeds are also used in the composition of some fire-works.

Red Fire.—The nitrate of strontia is the chief ingredient in the composition. A beautiful purplish flame is produced by a composition containing chlorate of strontia. To aid in reddening the flame of the former composition, a little lamp-black of the finest quality is generally used; for a red jet of fire from a paper case formed like that of a serpent, or of a Roman candle, &c., fifteen parts of pulverized gunpowder and four parts of dry nitrate of strontia; a slow and bright red fire, forty parts of nitrate of strontia, thirteen of pulverized sulphur, five of chlorate of potash, and four of sulphuret of antimony. In this last mixture, to avoid the danger of premature combustion, the chlorate of potash must not be ground in a mortar with the other ingredients, but ground separately, and afterwards mixed with them by shaking and stirring upon a sheet of paper.

Green Fire..—Seventy-seven parts of nitrate of barytes, thirteen of pulverized sulphur, five of chlorate of potash, three of charcoal in powder, and two of pure arsenic. The same precautions to be taken as before with regard to the chlorate of potash. The effect of this composition, when burned on the stage of a theatre, is to give a cadaverous and unearthly aspect to the aetors. It occurred to us many years ago that an extension of some of the effects of De Loutherbourg's *Eidophusikon* might be easily and effectively adapted to the stage. Where the foot-lights are, or else above the proscenium or front of the stage, an apparatus might be contrived to throw variously-coloured lights upon the actors and the scenery in the representation of magical incantations supernatural appearances, &c. The disposition and reflection of these variously-coloured lights might be diversified in such a manner as to produce the most singular contrasts and unexpected effects.

Brilliant and sparkling Jets of Fire.—These are produced from compositions rammed into paper cases of various sizes. One of these compositions may consist of eighteen parts of pulverized gunpowder, five of bright steel-filings, and two of saltpetre; another of sixteen parts of pulverized gunpowder, seven of steel-filings, one of saltpetre, and one of sulphur.

Sparks.—The composition for these is mixed with pure alcohol. Small pellets of cotton are steeped in this mixture, and dried, after rolling them in pulverized gunpowder.

Stars.—Very brilliant stars, such as we see issue from sky-rockets, Roman candles, &c., may be made from a composition of one part of antimony in powder, two of pounded crystal, two of pulverized gunpowder, fifteen of saltpetre, six of sulphur, and two of zinc-filings. The composition for these and other stars is made into a stiff paste with gum-water or glue, and then cut into small cylindrical or square pieces, which are rolled in pulverized gunpowder and dried in the shade.

Brilliant Chinese Fire.—Four parts of charcoal, five of pounded cast-iron, eight of pulverized gunpowder, six of saltpetre, six of sulphur; or three parts of pounded cast-iron, eight of pulverized gunpowder, two of saltpetre, and one of sulphur; all rammed into paper cases or other cases.

Jasmine Flowers.—This beautiful fire is generally seen in the vertical fire-wheels, &c. When the composition is well made, the sparks drop down somewhat like burning flowers of the jasmine. Its excellence depends chiefly on the use, in the composition, of bright filings or raspings from the steel-springs of clocks or watches, carefully deprived of all the finer dust that may be amongst them. The minute shavings of steel, procured from turners in metal, may also be used. Compositions for this kind of fire, six parts of steel-filings or shavings, sixteen of pulverized gunpowder, one of saltpetre, one of sulphur; or five parts of same filings, &c., sixteen of pulverized gunpowder, one of saltpetre, one of sulphur; or four parts of filings, twenty of pulverized gunpowder, one of saltpetre, one of sulphur, and four of zinc-filings or raspings, or pounded zinc, rendered pulverized by being heated to about 205 of the centigrade scale. The compositions for the Chinese fire and the jasmine flowers are to be mixed up in the same manner. The sulphur, the pounded cast-iron, or the steel-filings, are mixed with the addition of a little pure alcohol, and then the other ingredients are added. It must be observed that the size of the particles of pounded cast-iron or of steel-filings should be proportioned to the size of the cases that are to be filled with the composition; the smallest filings, &c., being used for the smallest cases.

Bengal Lights.—The common ones are made of one part of antimony, five of saltpetre, and two of sulphur; the sparkling ones, of one part of antimony, two of fulminating composition (of fulminating mercury and gunpowder), four of saltpetre, and four of sulphur; or one, two, five, two parts of the same ingredients in their order; or one, two, six, one part of the same in their order. Vases are filled with these compositions, a light gunpowder dust sprinkled over the top, and the whole closed up by a piece of paper pierced with some holes from which pieces of quick-match project. These lights may be made of any size. They sometimes weigh upwards of 200 pounds.

It is necessary to warn the reader that fulminating mercury requires great caution in handling it; and, as it is so apt to explode, it had better be left out of the composition for these lights, or any other fire-works. Indeed the pyrotechnist has need to exercise the greatest possible caution in all his operations. For instance, it may, in ignorance, be imagined that no harm can happen from pounding gunpowder in a mortar along with iron or steel-filings, &c., and yet the most serious accidents may result from manipulations of this kind incautiously conducted.

One of the most formidable pyrotechnical inventions is the Congreve rocket. We have conversed with some officers who served in the war against the Burmese, and they described the effect of these rockets as appalling, not only to the Burmese, but even to the stout-hearted Britons who fired them off.

Without entering into any very minute description of the process of making such popular fire-works as the common sky-rocket, the Roman candle, &c., we shall content ourselves with a brief account of the general construction of these two. The common sky-rocket consists of a strong paper or thin pasteboard case, the lower end of which, where the cotton quick-match is inserted, is drawn so close by means of a cord as to leave only a circular opening of about one-third of the interior diameter of the case. This is technically called *choking* the case. The case, when dried after pasting, is placed in a hollow cylinder of wood, into which it fits. This mould is furnished with a moveable bottom having a central nipple and a tapering spike of iron, which last, entering the aperture at the lower end of the case, rises within it nearly to the top. The space left round this spike is filled gradually, and by repeated blows from a mallet upon a hollow rammer, with a composition of pulverized gunpowder, saltpetre, and charcoal, or of sixteen parts of saltpetre, twelve of elm charcoal, and four of purified flour of sulphur. The rammer, which fits the inner diameter of the case, and to which the mallet is applied, has in its centre a deep hollow adapted to the iron spike before mentioned. The composition which forms the charge of the case must be put in by small quantities at a time, and driven down compactly by regulated blows of the mallet upon the rammer. The filling of the case in this manner requires skill and experience, because if the charge is not uniformly compacted in the case the rocket will not rise evenly and regularly. When the charge has been driven a little higher than the top of the spike, a round piece of doubled paper is put in; and upon this one-half of the inner paper of the remainder of the case is folded down and rammed firmly, so as to close the case. This plug is then pierced with a few holes, and above it are placed, along with some of the composition, or with some gunpowder, the stars, sparks, &c., that are intended to appear when the rocket has reached its highest ascent. The top of the case is then covered in, and fitted with a paper cone. In signal-rockets, that are intended to end with a report without stars, &c., the round piece of double paper before mentioned is pierced with a hole in the centre, and a little gunpowder is pressed firmly in above it, but without crushing the grains. The top of the case is then choked *close*, and the paper cone fitted on. In some other rockets that contain what are called *decorations*,—that is, stars, sparks, serpents, crackers, &c.,—these are placed with meal-powder in a wider cylindrical case, which is fitted to the top of the case containing the charge. These rockets are also terminated by a conical cap. We may remark, that in our common rockets the conical cap is not sufficiently stiff to maintain its form invariably, and so to aid in the regular ascent of the rocket. The balance-stick has next to be fastened to the rocket. The length, thickness, and weight of this stick, require calculation to suit it to the dimensions and weight of the case. On the Continent, rockets have been made to ascend without sticks by means of a triangle of pasteboard passing round the case, or by means of three pasteboard wings glued to the case. Each of these wings forms an isosceles triangle, in height six interior diameters of the rocket-case, and a little more than two of these diameters at the base. Each of these wings must be glued on quite parallel to the axis of the case, otherwise the flight of the rocket will be irregular. A short stick with similar wings has also been employed for rocket-cases. It is stated that all these winged rockets rose beautifully, even in a violent wind and bad weather; but some allowance must surely be made for the lateral action upon them of a strong wind.

The Roman candle consists of a strong case of paper or of thin pasteboard, which is completely closed at the lower end. It is generally charged with the same composition as sky-rocket cases, alternating with gunpowder and stars, as follows:—First a small quantity of composition is placed at the bottom of the case, and rammed down compactly by a rammer and mallet; next a small quantity of gunpowder, and above that a star without any ramming, but a gentle push to secure the contact of the star with the gunpowder; then a quantity of the composition, which is rammed down as before; next a little more gunpowder and a star, and then more composition rammed down; and so on till the case is filled. The case is then closed by a piece of paper-match pasted round the outside, and twisted to a point at the top. The charges of Roman candles might be diversified by variously-coloured fires and stars, &c.

D. Vergnaud, Paris, 1828; and *Pyrotechny*, by G. W. Mortimer, London, 1853. (G. F. G.)

PYRRHICA (Πυῤῥίχη), a celebrated dance among the Greeks, which, according to Plato (*Leg.* vii., p. 815), was the representative of all war-dances. It is usual to assign its origin to Crete or Sparta, and to the mythical age. Pyrrichos is said to be the inventor of it; and it is undoubtedly Doric in its origin. It has been also referred to Pyrrhus or Neoptolemus, the son of Achilles, by many who were probably misled by the name. This Byron does when he says—

> "You have the *Pyrrhic dance* as yet;
> Where is the Pyrrhic phalanx gone?"

It was danced to the sound of the flute or other musical instrument, with very quick and light time, as the Pyrrhic foot (⏑⏑), which is connected with this pastime, still testifies. Plato, in the passage above quoted, describes it as representing, by rapid movements of the body, the way in which missiles and blows from weapons were avoided, and also the mode in which the enemy were attacked. In the non-Doric states it was probably performed only as a mimetic dance; for we read of its being performed by women to entertain a company. It was performed at Athens at the greater and lesser Panathenæa; and Julius Cæsar introduced it into the public games at Rome. It was much admired by the Romans, and was exhibited by Caligula, Nero, and Hadrian.

PYRRHO, the founder of a sceptical school of philosophy, was the son of Pleistarchus, a native of Elis, and flourished B.C. 336, in the time of Philip the Great. He was originally a painter, but subsequently devoted himself to the study of philosophy, having been the pupil of Anaxarchus, whom he attended to India. There he became acquainted with the magi of Persia and the gymnosophists of India. On his return to Greece he acquired great renown, and was presented by the Athenians with the freedom of their city. He lived to the age of ninety. Pyrrho was the chief advocate of the sceptical school of philosophy; and from him all those who adhered to such doctrines were called Pyrrhonists. Quite groundless is the statement of the Abderite Ascanius, that he denied that it could be proved that there was any thing in itself just or unjust, honourable or dishonourable. The principle of his philosophy was, that there existed no motive for belief to which one cannot oppose a doubt of equal weight. Thus he affirmed nothing, and denied nothing. Amongst his disciples were Timon of Phlius, and Nausiphanes, who taught Epicurus. The Life of Pyrrho has been written by Sextus Empiricus, and by Diogenes Laertius.

PYRRHUS, King of Epirus, was the son of Æacides, and a descendant, according to the ordinary account, from Pyrrhus, the son of Achilles, and was born about 318 B.C. The early part of his life was involved in misfortune. Scarcely was he two years old when his father was deposed by rebel subjects, and a general massacre took place among the royal family and their adherents. The infant himself was snatched from the very hands of the assassins, and carried away with difficulty to the court of Glaucias, king of the Taulantians. It is true that the decline of Cassander's power in Greece opened up a way for him to his father's throne; but he had only reigned five years when the adverse party among his subjects suddenly gained the ascendancy, and drove him to take refuge with his brother-in-law Demetrius. So hard, indeed, did misfortune press upon him, that he was at last glad to go into Egypt as a hostage for the prince just mentioned. At this point, however, the tide of events began to turn in Pyrrhus' favour. Admiring his great abilities, and his pleasing and virtuous bearing, Berenice, the wife of King Ptolemy, took the charge of his fortunes. The hand of her daughter Antigone was given to him in preference to many princely rivals. Money and men were then placed at his disposal, to enable him to take possession of his hereditary kingdom. Nor did success fail to accompany him to Epirus. His subjects received him with acclamation; he was appointed colleague to Neoptolemus, the sovereign who then occupied the throne; and his power grew so great that, in 295 B.C., he ventured to make away with his rival, and to wield the sceptre alone.

In 294 B.C. Pyrrhus began his aggressive policy by acquiring an ascendancy over Alexander of Macedonia. The overthrow of that impotent prince soon afterwards by Demetrius did not long retard his ambitious designs. His admirable qualities proved too strong for his former friend and brother-in-law. In a battle fought in Ætolia in 289 B.C. against Pantauchus, the brave general of his enemy, he won from the Macedonian troops not only victory, but generous admiration. They went home lauding his wonderful achievements in the fight, comparing him to that favourite monarch, the dead Alexander, and desiring an opportunity to transfer to him their allegiance and their services. No sooner, therefore, did they see his lofty plume and his crest of goat's horns before the city of Berœa in 287 B.C., than they went over to him in a body. It is true that, changing sides once more, they soon deserted him for their old general Lysimachus, and left him no alternative but to abandon Macedonia. Yet his exploits in this campaign had gained for him a reputation which extended to other countries, and which, in course of time, was the means of opening up before him a new path to victory and glory.

It was in 281 B.C. that the Tarentines, attracted by the military renown of Pyrrhus, implored him to assist them against the aggressive tyranny of Rome. Too impatient to wait until the rude winter was past, he embarked early in 280 B.C., and after being nearly engulphed by the boisterous waves of the Ionian, he landed on the coast of Italy, and commenced his measures. He first applied a rigorous system of reform to the pleasure-seeking city of Tarentum. The theatres were closed; all revels were proscribed; and the lounging citizens were subjected to military drill. Then taking the field, he made a vigorous attack upon a Roman army under the consul Lævinus, as it was crossing the River Siris. The hardy legionaries, indeed, like men accustomed to conquer, were loath to yield. During a whole spring day did they stubbornly grapple with him for the prize of victory. But he routed them with great slaughter, and began to take measures to improve his victory. By the orator Cineas he offered terms of peace to the Roman Senate. When these were disdainfully rejected, he advanced by forced marches to within 24 miles of the enemy's capital. The intelligence, that the army of Etruria had just arrived in Rome, induced him to retreat to winter quarters in Tarentum; but did not make him slacken in his efforts to accomplish the object of his enterprise. He continued to ply the Senate with proposals of peace until the spring arrived. He then took the field, and defeated the enemy in a hard-fought battle at Asculum in Apulia. Nor was it until he discovered how fast his army was wasting away, and how difficult it was to obtain any reinforcements from home, that he desisted from the attempt to bend the Romans either by negotiation or by force.

From this period may be dated the decline of the power and reputation of Pyrrhus. Invited over to Sicily in 278 B.C. to aid the natives against the Carthaginians, he entered upon his first course of disaster. It is true that, for some time after his landing, his arms were victorious. The enemy was everywhere put to the rout before him; the strong town of Eryx was taken by a brilliant *coup de main;* and the Punic invaders were driven to sue in vain for peace. But the failure of his attack on Lilybæum turned the tide of fortune. So completely did he lose the good-will of the Sicilians that he was glad, in 276 B.C., to depart ingloriously for Italy. Nor was misfortune left on the shore behind him. As he was crossing the strait, the Carthaginian fleet, attacking him, destroyed seventy of his ships. When he landed, the warlike Mamertines, who had hastened from Sicily to intercept him, harassed his march towards Tarentum. The Romans also, two years afterwards, gained the complete mastery over him. His forces were cut to pieces at Beneventum by the consul Curius; and there was no alternative left for him but to return to Epirus, beggared in resources, and with a mere handful of soldiers. A short interval of prosperity intervened in the life of Pyrrhus after his arrival in his own kingdom. Invading the territories of Antigonus, King of Macedonia, and coming to an engagement with the troops of that prince, he routed the Gauls which formed the rear of the hostile army, brought the Macedonian soldiers over to him by holding out his hand invitingly, and thus gained a kingdom by one magnificent stroke of combined force and persuasion. But this success only tempted him to rush into new calamities. Consenting in 272 B.C. to interfere in the quarrels of Cleonymus, the ex-king of Lacedæmon, he hazarded a rash attack upon Sparta. The attack roused the deathless Spartan valour, and he was soon forced to desist. Still more unfortunate was the attempt which he then made to co-operate with Aristeas, the leader of one of the factions in Argos. Admitted by Aristeas during the night into the distracted city, he was immediately detected. The alarm was raised, those of the opposite party seized the strongest positions in the town; and he and his men were soon hemmed in on all sides. Day dawned, and found him fighting his way back amid a weltering sea of enemies. He had cut his passage as far as a narrow street, and was dealing blows of death upon all around him, when an old woman, looking down from a roof immediately above, and seeing him in the act of overpowering her son, seized a large tile with both her hands, and let it fall upon his head. The blow struck him senseless from his horse; and one of his antagonists, dragging him into a porch, despatched him with an Illyrian blade. (See Plutarch's *Lives.*)

PYTHAGORAS, a celebrated ancient philosopher, and, according to a well-known story related by Cicero (*Tusc. Quæst.* v. 3), the first who adopted that title, was a native of the island of Samos. Of the personal history of this man, to whom perhaps the most remarkable school of Greek philosophy owed its origin, and who, himself one of the earliest speculators in his country, plainly exercised no small influence over his successors, little can be known for certain, nor are his philosophical tenets free from much doubt and obscurity. From a time shortly subsequent to his own age the most improbable legends seem to have been connected with the name of Pythagoras, arising probably in a great part from the extravagant esteem and reverence in which he was held by his disciples. Even the period in which he lived cannot be determined with anything like accuracy; the different accounts, all of them long posterior to the time in question, exhibiting a variation of about forty years. The testimony of all these accounts, however, furnishes us with two historical landmarks by which we may date the principal event in his life, and thus, approximately, the time when he flourished. All our authorities agree in representing him as leaving Samos during the reign of Polycrates as tyrant there (B.C. 532–22); and settling in Italy while Tarquinius Superbus was king of Rome (B.C. 532–508). Thus, as these events could not have been far removed in point of time, we may assume as probable that they took place sometime between 530 and 520 B.C. If we credit the statements of Aristoxenus and Iamblichus, we shall place the birth of Pythagoras about 570 B.C.; but if, on the other hand, we incline to the views of Eratosthenes and Antilochus, we must carry back the date nearly to 609 B.C. Perhaps none of the authorities is worthy of implicit credit, but the former account certainly appears in itself to be more probable; for it is unlikely, as we must on the other alternative suppose, that Pythagoras did not begin the great work of his life till he was considerably above seventy. The date given by Ritter, on the authority of Clemens Alex. (Ol. 49, B.C. 584–80), does not materially differ from the former of the two above mentioned. His father's name was Mnesarchus (Herod. iv. 95), and his family is said to have sprung from the Tyrrhenian Pelasgians, who were largely intermixed with the Greek settlers in Samos.

Of the early life of Pythagoras our knowledge may be said to be absolutely nothing. The island where he probably spent the first years of his life was then in arts and commerce one of the most flourishing communities in the world. It lay, too, in the very region where the earliest of the Greek philosophers were then conducting their magnificent speculations, with which the young philosopher was no doubt familiar; and we can form some idea of the influences that prompted him, with high hopes and daring enterprise, to follow their footsteps into the new field, not then, as now, strewed with the ruins of theories and systems. Tradition has ascribed to Pythagoras, as instructors in philosophy, various of the early sages, and especially Pherecydes of Syros; but as far as opinions are concerned, he does not appear to be indebted to any of them. As little is there any ground for supposing that the philosophy of Pythagoras was of foreign origin, though he seems undoubtedly to have been an extensive traveller in foreign countries. His scientific attainments must have been great for that age; and in all probability he soon acquired a great reputation for wisdom and ability. The mathematical sciences were those that chiefly attracted his attention, and he is reputed to be the author of several discoveries in geometry, music, and astronomy. The travels of the philosopher are said to have extended to Egypt and the East; countries which were then regarded by the Greeks as the repositories of all the highest wisdom. They would naturally, therefore, attract the attention of a searcher after truth: while at Samos he would have the utmost facilities for acquiring geographical knowledge, and penetrating into the most distant regions. It is vain to conjecture what effect these travels might have on him, or what were the peculiar influences with which he was brought in contact. From the priests in Egypt or the Magi in Persia he may have acquired a knowledge of their hidden lore; but it is equally probable that he was not thus initiated, and it is not necessary to have recourse to any such sources for his opinions, so far as we know them.

On his return to Samos after his travels, Pythagoras seems to have fully formed his great project which he afterwards carried out. This project was more of a religious and political than of a philosophical nature. It was to establish a society on a religious foundation, and with an ethical end, for the moral improvement of its members, who were to be instructed in a peculiar mode of life. (See Plato, *Rep.* x. 600 B.) He probably found that such a scheme was impracticable under the government of Polycrates, and for that reason, rather than any personal dislike to him, left his native island and migrated to Crotona. We do not know what induced him to select this place in particular as the scene of his new experiment. It was one of the colonies which the Greeks had at this time sent out in such numbers to Southern Italy as to obtain for that part of the country the name of Magna Græcia. It was not unnatural that Pythagoras should look in this direction for a place to settle in. These colonies were comparatively young communities, many of them rapidly rising in importance, opening up to Grecian enterprise new and unexplored regions; and he might reasonably hope to find fewer obstructions to his plans there than among the intricate political relations of the eastern world.

Crotona itself stood in the country of the Bruttii, one of the most savage of the native Italian tribes. It was an Achæan colony, founded in 710 B.C., on a projecting headland nearly half-way between Sybaris on the N. and Locri on the S., while behind it stretched the primæval forests and mountain pastures of Sila. The government of the colony was at that time aristocratic, but the power of the nobility, though superior to any other, was not unquestioned; and the arrival of the philosopher added strength to the dominant party, whose cause he embraced; for he came with no small pretensions, and already many marvellous stories were in circulation about him. He was said to have received many of his doctrines from Empedoclea, the priestess of Delphi; to have been initiated into the mysteries of the Idœan cave in Crete; to have shown at Olympia a golden thigh rivalling the mythical shoulder of Pelops; to have received from Hermes the gift of recollecting all the stages of his previous existence; and to have given many other proofs of a supernatural intercourse with the unseen and celestial powers. These honours were undoubtedly claimed for him, either by himself or by his followers, and their effect is said to have been such, that he was reverenced by the Crotoniats as the Hyperborean Apollo. The accounts which we have of the wonderful change effected at Crotona after his arrival may be dismissed as belonging to the same class with those which narrate his superhuman dignity and exploits. We cannot doubt, however, that here Pythagoras so far succeeded in his designs as to form a secret society, partly religious and partly political, which exercised a great influence in the city, and spread the doctrines of its founder over the other cities of Magna Græcia, where branches of the original society were probably established.

The sudden and violent catastrophe which soon after befell these societies was the occasion of a wider dissemination throughout Greece of the opinions they maintained. The constitution of Crotona had become, since the arrival of Pythagoras, more decidedly aristocratic than ever: the Pythagoreans are said to have even entertained a project for abolishing altogether the popular assembly. Meanwhile the neighbouring city of Sybaris had undergone a revolution; the popular party gained the upper hand there; and one of their leaders named Telys established himself as tyrant. Five hundred of the opposite party left the city and took refuge in Crotona; and when Telys sent to demand them to be given up, the Crotoniats, at the instigation of the Pythagoreans, refused to do so. A war between the two cities was the result, in which the army of Crotona, under Milo, a Pythagorean, defeated a much superior force of Sybarites, and took and destroyed the city. A dispute then arose among the victors about the distribution of the spoil and conquered territories. The Senate, supported by the Pythagoreans, proposed to retain the whole as public property; but the people, indignant at this, rose in a body, and directing their rage mainly against the Pythagoreans, set fire to the house of Milo, where they were assembled, put many of them to death, and dispersed the rest. A general persecution of the sect throughout Magna Græcia ensued, and the disorder and bloodshed was only ended by the interference of the Achæans in Greece, who established in Crotona and the other cities, a democratic government. Whether or not Pythagoras was personally involved in the outbreak at Crotona, which happened in 504 B.C., is not certain; he is generally supposed to have retired to Metapontum, where he died, and where the exact spot of his death was still pointed out in the time of Cicero. (*De Finibus*, v. 2.) The date of his death, and the age to which he lived, are as variously reported as that of his birth. The earliest date given for his death is 510, the latest 472; while, according to another account, it took place in 500. According to Iamblichus, who takes the latest date for his death, Pythagoras presided in his school thirty-nine years; while his whole life is generally said to have been ninety years, though some make it only eighty, and others as much as one hundred and four.

Of the philosophy of Pythagoras, as a whole, it is not difficult to ascertain the general character and principles; but when we descend to the minute details, the notices that we possess are so obscure and unconnected, that it only requires a little ingenuity to find in the Pythagorean doctrines any preconceived system that the critic may prefer. This indeed has been attempted more than once in the interest of different schools. The Neo-Platonic philosophers saw their own peculiar tenets in the philosophy of Pythagoras; and some learned Christians have found there the doctrine of the Trinity, and have identified the celebrated *Tetractys* of the Samian with the *Tetragrammaton*, or incommunicable name of the Supreme Being among the Jews. The truth is, that we have not the materials to enable us to re-construct the system of Pythagoras, or to state very minutely any of its particular doctrines. It is all but certain that the founder of the school committed none of his speculations to writing; and our knowledge of his opinions is derived from the fragments that remain of the later Pythagoreans, and from the notices of other philosophers, especially of Aristotle. He indeed is by far our safest authority on the subject; for we cannot take the representations of later writers, especially those of the Neo-Platonic school, without making allowance for their remoteness in point of time, and for their own peculiar philosophical opinions.

The peculiar form assumed by the Pythagorean philosophy seems to have been derived from those mathematical studies in which its founder was proficient. The principles of mathematics were supposed to be the principles of all real existences; and as numbers are the primary constituents of mathematical quantities, and at the same time present many analogies to various realities, it was further inferred that the elements of numbers were the elements of realities. Now the elements of numbers were considered to be the odd and the even; the former of which was regarded as limited, and the latter as unlimited. (Arist. *Metaph.* i. 5.) Unity, again, seems to have been viewed in a twofold light: on the one hand as identical with the odd or the limited; and on the other as partaking of the nature both of the odd and of the even, and being the source of both. Thus all things depend on numbers; numbers themselves on the two principles odd and even; and these, again, on the primary unit. The doctrine was further illustrated by an arrangement of the principles of things in ten pairs, not as twenty distinct and separate principles, but as ten several ways of expressing the two great principles. The first three of these pairs are the most important, and they are—the limited and the unlimited,—the odd and the even,—the one and the many; while the peculiar character of the principles are brought out by the names which occur lower down in the list—light and darkness, good and evil. The latter member of each antithesis was regarded as inferior to the former (Arist. *Eth. Nic.* i. 6), and as being in fact somehow a mere negation of it. Thus the one, the odd, the limited, was in reality the only cause of all; the many, the even, the unlimited, being a mere nonentity, till called into existence by union with the other. We see then, under what to us appears a fanciful and cumbrous symbolism, a system of pantheism. As numbers are evolved from unity, so from the primary unit all the universe is evolved; or in other words, as we are told by Cicero (*De Nat. Deor.* i. 11), Pythagoras held that the Deity was the soul of the world, diffused throughout all its parts. The origin of evil was by this system referred not so much to the primary unit as to the second negative principle, without which it was impossible for the world to exist.

Such were the fundamental principles of the Pythagorean philosophy; and so far as they are concerned there is little doubt. But the theory of numbers was carried to a much greater length, and with much more minuteness of detail, for besides the unit, a special meaning was attached to each separate number up to ten. Here it is safest at once to confess our ignorance, for we leave the region of well-ascertained facts, and enter one where plausible conjecture is the best that we can put in their place. The view of Alexander Aphrodisiensis, followed by Ritter, that the monads being points, and the unlimited, void space; the duad is the line, composed of two such monads, with the intervening space; the triad, the surface, of three monads; and the tetrad, the solid, of four such; was probably held by some of the Pythagoreans, though it has been doubted whether Pythagoras himself taught it. We must suppose that his theory of the material world resembled it in this, that it was idealistic in its character, resolving matter into mere negative or immaterial principles. The pantheism of Pythagoras was certainly more akin to the idealistic than to the materialistic form of that theory. The way in which the principle of numbers was carried out by Pythagoras in natural philosophy is illustrated by his astronomical speculations. He assumed that the number of the heavenly spheres could be neither more nor less than the perfect number ten, which played an important part in his symbolism; and in order to make up this number, supposed the existence of another body, the counter-earth (ἀντίχθων), on the other side of this earth. Thus the ten spheres revolving round the central fire, which had the form of a cube, and was called the watch-tower of Zeus, were those of the counter-earth, the earth, the moon, the sun, the five planets in order, and the fixed stars,—the whole universe thus forming a sphere. The perfection and harmony of the whole was reconciled with the too obvious evils prevalent in this mundane sphere, by supposing that the earth was the principal seat of the imperfection in the world, being the second in number, and thus associated with the principle of evil in the Pythagorean system—the even, the many, the unlimited. Further, as the intervals between the several spheres and the velocities of their motions were regularly proportioned according to the musical scale, hence arose the doctrine of the music of the spheres (Cic. *De Nat. Deor.* iii. 11), which is inaudible to us, either from the effects of custom, or from being too powerful for our faculties. The doctrine of numbers, when thus carried into physical science, seems to have been regarded by the Pythagoreans rather as deriving illustration than scientific proof from the phenomena, for they considered objects to be an imitation of the numbers (*μίμησις τῶν ἀριθμῶν*. Arist. *Metaph.* i. 6).

The psychological opinions of Pythagoras were not less memorable or characteristic than the other parts of his system. In accordance with his theory, the soul was termed a number or a harmony, and was regarded as homogeneous with the divine soul of the world, from whence it sprung. An immaterial principle was thus asserted, capable of existing apart from the body; and indeed the pre-existence of the soul, before entering its present body, was with Pythagoras, as with Plato afterwards, a conspicuous article of belief. After its departure from the body at death the soul may, according to the celebrated doctrine of metempsychosis, pass into another body, and that not necessarily a human body, but often that of one of the lower animals. Pythagoras himself professed to have once animated the body of Euphorbus, the son of Panthus; and, as Horace says,—

> "Clypeo Trojana refixo
> Tempora testatus; nihil ultra
> Nervos atque cutem morti concesserat atræ." (*Od.* i. 28.)

There must indeed always be some sort of fitness or adaptation of the soul to the body it assumes, and it is as a punishment that it is compelled at all to assume a corporeal nature, in which it is, as it were, buried. Thus, while the wicked have their final place of abode in Tartarus (Arist. *Anal. Post.* ii. 11), the good on the other hand are raised to the highest position. The Pythagorean psychology, according to one account, recognised two, and, according to another, three parts in the soul. According to Cicero (*Tusc. Quæst.* iv. 5) it was divided into a rational and irrational part; the former peculiar to man, and the latter common to the brutes; but the account given by Diogenes Laertius, from its peculiar phraseology, is more likely to represent the views of Pythagoras. That part of the soul which is peculiar to man is there called φρένες, and located in the brain, the νοῦς, also placed in that organ, and the θυμός, which had its seat in the heart, were possessed also by the lower animals.

The science of ethics owed much to the Pythagorean school; for, according to Aristotle, they were the first who attempted anything in this field. It is impossible to ascertain with any certainty or distinctness, what were their peculiar opinions on this subject. The same peculiar phraseology was kept up here also, and they attempted to express, by means of numbers, such ideas as virtue, justice, marriage, and opportunity. (Arist. *Metaph.* i. 5; xii. 4.) The whole doctrines of the sect were probably made in some degree, like those of Platonism, subservient to ethical purposes, and the precepts that were inculcated seem to have been intended for the production in the soul of that order and harmony which characterize the external world. They partake very much of an ascetic character, recommending the controlling of the passions and desires, the endurance of bodily hardships of all kinds, and the observance of the duties of friendship, for which some of the sect became very celebrated. On political subjects the opinions of Pythagoras were, as we have already seen, inclined towards aristocratical institutions, in which he would probably see more of that order and harmony which constitutes excellence on his view, than in the more popular forms of government.

It now only remains to state briefly the chief facts known about the peculiar external observances of the Pythagorean societies. They possessed much of the character of the ancient mysteries or secret societies wherein peculiar doctrines were taught that were hidden from the vulgar eye. Candidates for admission were not initiated until they had passed through a lengthened course of probation, one part of which consisted in the injunction of silence for a period. The members admitted were divided into several classes, according as they were more or less intimately acquainted with the peculiarly sacred and mysterious doctrines of the sect; though, from the diverse statements of ancient authors, it is impossible to say for certain what was the number or names of these classes. They lived together, taking their meals at a common table, and engaged in common in those exercises, especially of gymnastics and music, which were held to be conducive to their bodily and mental wellbeing. Implicit faith in the founder of the system was inculcated; so that their formula of asseveration, "ἀυτὸς ἔφα," became proverbial. There were, besides, various symbolical observances enforced, such as abstinence from animal food, from fish, and from beans; but considerable doubt and obscurity hang over these injunctions, though they are noticed by several of the classical writers. Perhaps we will acquire the most correct views of the Pythagorean mysteries or orgies if we adopt the opinion of Herodotus (ii. 81), who identifies them with those of Orpheus and Bacchus, a view which seems to be confirmed by general similarity of the Pythagorean to what we know of the Orphic doctrines. Orpheus seems to have taught a system of pantheism; and it is remarkable that Virgil, in his description of the lower world, where he seems partially to adopt Pythagorean principles (*Æn.* vi. 724–752), introduces as an important personage the long-robed Thracian priest. On this view we may suppose that much of what Pythagoras embodied in his system formed part of a previously existing religion, and was made by him a vehicle for conveying his peculiar doctrines with more authority to his disciples. Thus perhaps the theory of metempsychosis was but a peculiar form into which the doctrine of immortality and a future retribution was cast. A very similar theory to that of the philosopher is certainly adopted by Pindar (Ol. ii.), within a time apparently too short for a totally new doctrine to have gained acceptance. All that belongs to the theory of number must evidently be ascribed to Pythagoras himself; but it is not improbable that many of his minor doctrines and peculiar precepts were borrowed from previously existing notions and observances. Even the scantiness of our knowledge of Pythagoras cannot conceal from us the fact that he must have been one of the most remarkable men that have ever lived. As to his philosophy, perhaps the highest praise we can give it is, that it contributed greatly to give rise to the lofty speculations of Plato, of whom he was the precursor; and as to his institutions, they long survived to perpetuate the memory and fame of their founder. (See Ritter's *History of Ancient Philosophy;* Smith's *Dictionary of Greek and Roman Biography;* Archer Butler's *Lectures on the History of Ancient Philosophy*, &c.)

PYTHEAS, an ancient navigator, was a native of Marseilles, and is supposed to have lived some time about the age of Alexander the Great, 330 B.C. We have no information respecting the private circumstances of his life, but we know that he explored the northern seas of Europe, though the ancient geographers appear to have placed little dependence on the statements which he made. Both Polybius and Strabo treat him with great severity, and ridicule his accounts as absurd and incredible. Modern writers are inclined to set more value upon the narrative of Pytheas. It would appear that he sailed through the English Channel, and, after leaving Britain, a voyage of six days to the north brought him to an island which he calls Thule, where he says that the sun never descends below the horizon for a certain period at the summer solstice. This statement would apply to Iceland, but then it seems unlikely that he could reach that island within six days. He next sailed to the N.E., and entering the Baltic, reached a river which he calls Tanaïs, and is thought by Ukert to be the Elbe. Here he found a people who made use of amber instead of wood; and as that substance is still found in large quantities in Prussia, there is little doubt that he must have visited this part of Europe. He gave an account of his voyages in two works which he published. The one was a *Description of the Ocean*, and contained his voyage from Gades to Thule; the other work was entitled *Periplus.* He appears to have been the first to determine the latitude of a place from the sun's shadow. It is said that Pytheas was the first who suspected that the tides were influenced by the moon. (See *Eclaircissements sur la Vie et sur les Voyages de Pythéas*, by Bougainville, in the *Récueil de l'Académie des Inscriptions*, xix. 46; also the discussions of D'Anville, of Ukert, of Arvedson, of Fuhr, and of Straszewick.)

PYTHIA. See Delphi, and Oracles.

PYTHIAN GAMES, one of the four great national festivals of the Greeks, was held near Delphi, anciently called *Pytho*, in honour it is said of Apollo, who slew Python, a monstrous serpent, near that place. The Crissæan plain, where those games were celebrated, contained a hippodromus, or race-course, a stadium of 1000 feet in length, and a theatre where were held the musical contests, the most important part of the Pythia. According to most legends, these games were instituted by Apollo himself. Previous to Ol. 48 they had been celebrated at the end of every eighth year; but afterwards, like the Olympia, they were held at the end of every fourth year. According to Böck, they were celebrated in the spring, in the month of Bucatius, which must have corresponded with the Attic Munychion. During the first Pythiad the victors received χρήματα as their reward, but in the second the reward was a laurel chaplet. The Pythian games were most probably held as long as the Olympic, that is, down to A.D. 394. (Krause, *Die Pythien, Nemeen, und Isthmien.*)

PYX, Trial of the. See Coinage.

Q.

Q, the seventeenth letter and thirteenth consonant of our alphabet, but one not to be found either in the Greek, old Latin, or Saxon alphabets; and indeed some would entirely exclude it, seeing that *k* fully supplies its place. The *q* is never sounded alone, but in conjunction with *u*, as in *quality*, *question*, *quite*, *quote*, and the like, and never ends any English word. As a numeral, Q stands for 500; and with a dash over it, thus, $\bar{Q}$, for 500,000. Used as an abbreviation, *q* signifies *quantity* or *quantum*. Thus, amongst physicians, *q. pl.* is *quantum placet*, as much as you please; and *q. s.* is *quantum sufficit*, as much as is necessary. Q. E. D. amongst mathematicians, is *quod erat demonstrandum*, which was to be demonstrated; and Q. E. F. is *quod erat faciendum*, which was to be done. Q. D. amongst grammarians is *quasi dictum*, as if it were said, or, as who should say. In the notes of the ancients, Q stands for *Quintus* or *Quintius*; Q. B. V. for *quod bene vertat*; Q. S. S. S. for *quæ supra scripta sunt*; Q. M. for *Quintus Mutius*, or *quomodo*; Quint. for *Quintilius*; and Quæs. for *quæstor*. (See ABBREVIATIONS.) For the changes to which this letter is liable, see C and K.

QUADI, a warlike German tribe, whose territories were situated between the Danube, the Bohemian mountains, and the River Marus. They make their first appearance in history in the first century as formidable foes of the Romans. Their bodies were covered with mail, consisting of plates of horn; their weapons were long spears; and each man had three swift horses for his use in battle. Thus equipped, they commenced the practice of making rapid and sweeping raids into Pannonia, Mœsia, and other neighbouring provinces. Sometimes they routed the imperial forces which tried to check their inroads. At all times they returned home with their predatory spirit unbroken. No reverses, in fact, however frequent, could daunt those wild border troopers of the Danube. The emperors Marcus Aurelius, Probus, Carus, and Valentinian I., defeated them without subduing or crushing them. The last glimpse that we get of them in history shows them in company with other barbaric hordes, in 407, overrunning Gaul, and revelling in boundless havoc and slaughter.

QUADRANGLE, or quadrilateral, a figure consisting of four sides and four angles situated in the same plane.

QUADRANT (*Quadrans*), in geometry, the arch of a circle containing ninety degrees, or the fourth part of the entire periphery. The name is also applied to a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars, as also for taking angles in surveying. This instrument is variously contrived, and furnished with different apparatus, according to the various uses for which it is intended; but they all have this in common, that they consist of a quarter of a circle, the limb of which is divided into ninety degrees. Some have a plummet suspended from the centre, and are furnished with sights to look through. The principal and most useful quadrants are the common surveying quadrant, the astronomical quadrant, Adams's quadrant, Cole's quadrant, Gunter's quadrant, Hadley's quadrant, horodictical quadrant, Sutton's or Collins's quadrant, and the sinical quadrant. The quadrant is now entirely superseded for astronomical purposes by the mural circle. (See MURAL CIRCLE, and SEXTANT.)

QUADRANTAL, the principal Roman measure of capacity for fluids. All the Roman measures were originally founded on weight. It was at first denominated *amphora*, and afterwards quadrantal, from its form, which was square every way, like a die. In capacity, it contained eighty *libræ* or pounds of wine, which made forty-eight *sextarii*, two *urnæ*, or eight *congii*.

QUADRATIC EQUATIONS. See ALGEBRA.

QUADRATURE, in geometry, denotes the reducing a figure to a square. Thus, the finding of a square which shall contain just as much surface or area as a circle, an ellipsis, or a triangle, is the quadrature of a circle, an ellipsis, or a triangle. The quadrature, especially amongst the ancient mathematicians, was a great postulatum. The quadrature of curvilinear spaces is of difficult investigation; and in this respect extremely little was done by the ancients, except the finding the quadrature of the parabola by Archimedes. In the year 1657, Sir Paul Neil, Lord Brouncker, and Sir Christopher Wren geometrically demonstrated the equality of some curvilinear figures to rectilinear spaces; and soon afterwards the same thing was proved both at home and abroad of other curves, and which were brought under an analytical calculus. The first specimen of this was given to the public in 1688 by Mercator, in a demonstration of Lord Brouncker's quadrature of the hyperbola by Dr Wallis's reduction of a fraction into an infinite series by division. Sir Isaac Newton, however, had before discovered a method of attaining the quantity of all quadruple curves analytically by his fluxionary calculus. It was disputed between Sir Christopher Wren and Mr Huygens which of them had first discovered the quadrature of any determinate cycloidal space. Leibnitz afterwards found that of another space; and in 1669 Bernoulli discovered the quadrature of an infinity of cycloidal spaces, both segments and sectors. (For the history of the quadrature of the circle, see the third supplement to the fourth volume of Montucla's *Mathematical Recreations.*)

QUADRATURE, in astronomy, that aspect of the moon when she is ninety degrees distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters.

QUADRIGA (*quatuor*, four, and *jugum*, a yoke), in antiquity, a car or chariot drawn by four horses harnessed all abreast. On the reverses of medals we frequently see Victory in a quadriga, holding the reins; and hence these coins are called *nummi quadrigati* and *victoriati*.

QUADRIO, FRANCESCO XAVERIO, a learned Italian writer, was born in the province of Valtellina in 1695, and entered the order of the Jesuits at the age of twenty. His uneasy disposition drove him about from one pursuit to another, before it fixed its attention on any particular subject. He first taught humanity at Padua. Then he studied and taught theology at Bologna. His next vocation was that of a preacher at Venice and Modena. At length he was found once more at Padua engaged in literary labours. It was there that Quadrio undertook the arduous project of writing a History of Poetry under all its different forms in every age and country. At first the execution of the plan went on prosperously. Pope Benedict XIV., and the eminent writer Cordara, cheered him on in his toils. He was indefatigable in rummaging the libraries of Venice, Milan, and Bologna, and in collecting materials from all quarters, He stated his facts and opinions with as much fulness and exactness as could be expected in a work of such a general character. The only part of the subject in which he glaringly failed was that which related to modern foreign languages. In course of time, however, his success began to be seriously impaired. Want of money gave rise to melancholy, and melancholy deranged both mind and body. Nothing but change would solace him. He wandered restlessly from one European city to another. He threw off the garb of the Jesuits, and appeared as a plain secular priest. His book itself was for a time laid aside. Even after it was resumed, he did not show his former untiring energy. When the work was at length completed, under the title of *Storia e Ragione d'Ogni Poesia*, 7 vols. 4to, Bologna and Milan, 1741–52, it appeared that some portions of the later volumes were mere compilations. Quadrio died at Milan in 1756.

QUADRUPLE, fourfold, or something taken four times, or multiplied by four, on which account it is the converse of quadripartition, or division by four.

QUÆSTOR (*quæro*, I seek), a name given to two distinct classes of Roman officers. Varro defines both as: Quæstores a quærendo, qui conquirerent publicas pecunias et maleficia—"Quæstors (from their *seeking*), who collect the public monies and investigate crimes." The one class, the *quæstores classici*, therefore, had to collect and keep the public revenues; the other, called the *quæstores parricidii*, were public accusers who convicted those guilty of any capital offence, and carried the sentence into execution.

QUAIL. See ORNITHOLOGY.

QUAINI, LUIGI, an Italian painter, was born at Bologna in 1643, and studied his art under Guercino, Carlo Cignani, and his father Francesco. A lively and versatile disposition soon made him a man of accomplishment. He became an adept in history, architecture, and music. In painting especially he manifested his easy dexterity. Although employed for a great part of his life in working on the same canvas with his brother-in-law Franceschini, he always succeeded in giving a distinct embodiment to his happy and graceful conceptions. His beautiful landscapes and exquisite perspectives were interesting and important features in the pictures which the two painted at Bologna, Modena, Piacenza, Genoa, and Rome. Quaini died in 1717.

QUAKERS.

Ideas commonly entertained of Quakers and Quakerism.

QUAKERS, a body of Protestant Dissenters, so named by the public at large, but styled by themselves, "The Society of Friends." This society was founded by George Fox in the year 1647. The Friends are remarkable for differing from the community in religious doctrines, mode of worship, and social customs, more than any other body of Christians; and it may safely be asserted that their character has been less understood, and more seriously misrepresented, than that of almost any other religious association of modern times. Mosheim, Neale, Formey, Voltaire, and Hume have given us descriptions of the Society of Friends, of which it would be difficult to say which abounds most in ignorant mistakes or wilful distortions. Of late years a fairer estimate of these people has manifested itself in the public mind. Men of deep thinking and eminent genius have been led to examine their history and writings, and have pronounced decisions upon them very different from those of the authors just mentioned. Coleridge, in his *Biographia Literaria*, says, "One assertion I will venture to make, as suggested by my own experience, that there exist folios on the human understanding, and the nature of man, which would have a far juster claim to their high rank and celebrity, if in the whole huge volume there could be found as much fulness of heart and intellect as bursts forth in many a simple page of George Fox." Thomas Carlyle, in his *Sartor Resartus*, pronounces George Fox "the greatest of modern reformers;" and Charles Lamb, in the *Essays of Elia*, declares, that "Sewel's *History of the Quakers* is worth all other ecclesiastical history put together."

We shall now proceed to give such an account of the rise, progress, and opinions of this society as an intimate acquaintance with it and the writings of its members enables us to furnish, and as will be found amply borne out by a careful reference to the most authentic records, and to its existing condition.

It has commonly been stated that this society was, at its commencement, termed the *Family of Love*, or *Seekers*. But this is a mistake The *Seekers* were a people of prior origin, and of very different notions. From their peculiar extravagance, they acquired the name of *Ranters*, and seem to have been the very people that Butler had in his eye when writing his *Hudibras*. They held that

> Saints may do the same things by
> The spirit in sincerity
> Which other men are tempted to,
> And at the devil's instance do,
> And yet the actions be contrary,
> Just as the saints and sinners vary.[1]

Origin of the term Quaker.

The attempt to confound the Quakers with this sect was one of the first acts employed by the enemies of Quakerism to stamp it with opprobrium. Fox occasionally fell in with them in his travels, and sharply reproved them for their errors. The Friends, for some time after they had been gathered into a distinct body, were known only by the name of "the Professors of the Light," or "Children of the Light," from "their fundamental principle, which," to use the words of William Penn, "is as the corner-stone of their fabric; and, indeed, to speak eminently and properly, their characteristic or main distinguishing point or principle, viz., the light of Christ within, as God's gift for man's salvation; the root of the goodly tree of doctrine that grew and branched out of it."[2] They were known by no other name till 1650, three years after the commencement of their society, when George Fox being brought before the magistrates of Derby for preaching there, and telling them to "quake at the name of the Lord," one of them, Gervase Bennett, an Independent, caught up the word, and called him and his friends *Quakers*. That was the real origin of the term Quaker; "a term which," says Sewel, their historian, "so caught the public fancy, and especially that of the priests, that they sounded it gladly abroad, never after that time giving any other name to the professors of the Light, so that it soon ran all over England, and making no stand there, it quickly reached the neighbouring countries; and that English name sounding very oddly in the ears of foreigners, hath given occasion to many silly stories."[3]

Real character of George Fox.

Perhaps to no great reformer has so little justice been done as to George Fox. Beyond the pale of his own society his character has in fact never been understood. By some grave and even eminent writers he has been denounced as a silly enthusiast; by others as a blasphemer; and others, again, have denied that he was the founder of Quakerism at all. No statements can be more at variance with the truth. For three or four years after his first setting out he was the sole preacher of the society.[4] It was he, as may be abundantly seen in the histories of the society, and the writings of his most celebrated disciples, who gave its character and constitution to this religious association. They are his opinions, his feelings, his tone of mind, which stamped it with its peculiar form and spirit. That in the fervour of his enthusiasm, and the elation of brilliant success, he ran into some fanatical extravagances, and even absurdities, is what is perhaps inseparable from the career of a sanguine advocate of great moral and social changes; and we shall soon point to some of these, in tracing his exertions for the organization of his infant society. There have indeed been one or two documents, a letter to Cromwell, and a letter to himself from the wife and daughters of Judge Fell, raked up out of a vast mass of manuscripts left behind him, and eagerly and repeatedly pushed before the public by his enemies, and recently again by some seceders from the Quakers themselves, in order to stamp him as a blasphemer, and a man open to the silliest adulation. It is not by such a mode, however, that the genuine character of any man is to be decided, but by a careful examination and candid judgment of his whole life and works. Did we apply so one-sided and unphilosophical a test to that of any great reformer, what should we now think of Luther, Jerome of Prague, Calvin, Knox, Wesley, or many others? If we shut our eyes to the nobler points of their characters, and opened them only to their defects; if we estimated Jerome of Prague by his recantation, Luther by his notions of combats with the devil, Calvin by the burning of Servetus, Knox by his zeal in the demolition of cathedrals, or Wesley by his belief in omens and apparitions, what an absurd verdict should we pass upon these great men! Such, however, has generally been the mode of judging of George Fox; whilst his labours, and religious and moral doctrines recorded by himself and the historians of the society, mark him as one of the most extraordinary men of his age. We shall soon have to observe upon how many important points of morals and manners he called in question the received opinions of his time; for whatever his sagacious mind had once embraced as truth, he had the integrity and boldness to proclaim everywhere. He advanced into the presence of princes, and proclaimed it there in the same fulness, and with the same ease and freedom, as he did amongst his own peers. Yet with this daring and determined spirit, his contemporary disciples are unanimous in attesting his gentleness and unassuming modesty amongst them. The testimony of his eminent friend William Penn, who had seen much of society in all its gradations, is that of all those who knew him best. "He was a man that God endued with a clear and wonderful depth; a discerner of others' spirits, and very much master of his own. . . . He was of an innocent life, no busy-body nor self-seeker; neither touchy nor critical. . . . So meek, contented, modest, easy, steady, tender, it was a pleasure to be in his company. He exercised no authority but over evil, and that everywhere and in all; but with love, compassion, and long-suffering. A most merciful man, as ready to forgive as unapt to take or give an offence. Thousands can truly say he was of an excellent spirit and savour amongst them, and because thereof the most excellent spirits loved him with an unfeigned and unfading love."[1]

Formation of the Society of Friends.

George Fox was born of humble parents at Drayton in Leicestershire. In the quaint language of Sewel, "his father was Christopher Fox, a weaver by trade, an honest man, and of such a virtuous life that his neighbours used to call him righteous Christer. His mother was Mary Lago, an upright woman, and of the stock of the martyrs."[2] George was put apprentice to "a shoemaker that dealt also in wool and in cattle;" but he became most attached to the agricultural part of his master's business. His humble origin and education have often been adverted to, as implying a stigma upon Quakerism; but it is unquestionably to this circumstance that Quakerism owes its most distinguishing features, and probably the greatest amount of good that it has done, or may yet do, in the world. As Fox grew up, pursuing his solitary occupations in the fields, his strong mind soon began to employ itself on the subject of the utmost moment to a mortal creature, the grounds of his hopes of a future existence, and the true understanding of the Scriptures. That which, at a first view, seemed to be a disadvantage to Fox, his want of learning and his obscurity of station, have, through the native vigour of his intellect, become eminently advantageous. His mind was neither trammelled by creeds, nor directed by classical or other knowledge, nor misled by the glimmerings of school philosophy. He was thrown, by his absolute want of a higher education, on his Bible. The whole strength and earnestness of his understanding were concentrated on the inquiry into the doctrines it contained; and he seems, with a wonderful clearness and singleness of eye, to have at once comprehended the pure and simple system of the Christian faith. He embraced it heartily and for ever. No bias of selfishness, no hopes of honour or of gain, ever appeared to weigh with him for a moment; it was to Christianity for itself alone that he attached himself, and he set out to proclaim it in the face of the world, with that boldness which always distinguished him. At first his travels were principally through the midland counties, where he convinced great numbers of his principles. For four years he appears, as already stated, to have been the only preacher of those principles; and, what is singular, the second preacher of Quakerism was a woman named Elizabeth Horton. In the fifth year of Quakerism there were, however, according to Sewel, no less than twenty-five preachers, and in the seventh year upwards of sixty. These, traversing the kingdom in all directions, excited an extraordinary commotion. But in order fully to understand the uproar which the preaching of Quakerism created, it is necessary to call to mind the features of that age, and to see what the doctrines of Fox really were.

The age of George Fox.

George Fox made his appearance just as the struggle between the crown and the people was drawing to a close. Charles I. was already in the hands of the Parliament. The monarchy had been destroyed, and the public mind was full of new schemes of liberty and legislation. Then came the struggle between the Parliament and the military power. Not only the monarchy and the Parliament, but the church establishment itself, fell. Men soon began to grow weary of alternate tyranny and lawlessness both in ecclesiastical and in political matters. They were disgusted, too, with the greediness of priests of different denominations, struggling shamelessly for power and wealth. The diffusion of the Scriptures during the respective reigns of Henry VIII., Edward VI., and Elizabeth had now made them pretty common in the hands of the people. Thousands and tens of thousands were scattered throughout the country, who were become dissatisfied with the old institutions, and anxious to ally themselves with some body, the doctrines and practice of which were more consonant to their newly-awakened ideas. But they were not merely on the watch; they were in a state of high excitement. The novelty and animating nature of the doctrines of the gospel, and perhaps still more the splendour of eastern metaphor exhibited in the prophetical writings, had thrown them everywhere into a sort of spiritual intoxication. When, therefore, George Fox made his progress through the country, his voice was like a trumpet to collect around him hosts of inquirers. Priests, notwithstanding the opposition of their order, left their pulpits; officers in the army, judges, gentlemen, mechanics, and husbandmen; all classes, indeed, flocked round him, and found in his system of a free gospel, and renouncement of the vanities of the times, that which they had hitherto sought for in vain.

Doctrines of the Friends.

The doctrines which Fox taught, and which have been received and are still held as the true faith by the Society of Friends, are principally the following:—

1*st.* The great foundation and corner-stone of Quakerism, as William Penn justly terms it, is the doctrine of the Inward Light, founded on various passages of Scripture, but especially on the words of the gospel according to St. John, that "Christ is the true Light which lighteth every man that cometh into the world." They believe in the words of a document, issued by themselves, that "every man coming into the world is endued with a measure of this light, grace, and spirit of Christ, by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his nature; and that without the spirit inwardly revealed, man can do nothing to the glory of God, or to effect his own salvation."

2*d.* The spirituality of Christianity is a doctrine which flows directly from this root, and hence they believe in the non-essentiality of religious ceremonies. "We think," say they, "this influence (the influence of the Spirit of Christ) especially necessary to the performance of the highest act of which the human soul is capable, even the worship of the Father of lights and spirits, in spirit and in truth; therefore we consider as obstructions to pure worship all forms which divert the attention of the mind from the secret influence of this unction from the Holy One. (1 John ii. 20–27.) They cannot, therefore, admit of any fixed liturgy, any stated forms of prayer, or any regular preaching. "Yet, although true worship is not confined to time and place, we think it incumbent on Christians to meet often together (Heb. x. 25), in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength; nevertheless, in the performance of worship, we dare not depend for our acceptance with him on a formal repetition of the words and experiences of others; but we believe it to be our duty to cease from the activity of the imagination, and to wait in silence to have a true sight of our condition bestowed upon us." On this ground the sole outward act of worship amongst the Friends consists in meeting together and sitting down in silence, without any singing, or stated prayers or sermon.

3*d.* From the same great fundamental tenet of the society it directly flows, that as this influence is absolutely necessary to the performance of individual worship, it is more especially so in the exercise of the ministry. There can be no preaching unless the preacher immediately feel himself moved to speak; therefore there can be no electing of particular individuals by the church, or education of them for the office of the ministry. It implies a ministry entirely of divine ordination, and without the participation of any human authority. According to this faith, there is and can be no paid priesthood. The gospel is a free gift to be freely exercised.

4*th.* The Friends do not hold the doctrine of the Trinity according to the common acceptation of the word. They think it safest on this mysterious subject to confine themselves to the terms of Scripture; and these are the words of their confession on this subject:—"We agree with other professors of the Christian name in the belief in One Eternal God, the Creator and Preserver of the universe; and in Jesus Christ his Son, the Messiah and Mediator of the New Covenant (Heb. xii. 24)."

5*th.* The belief in the entire spirituality of the gospel system has led the Friends to consider some rites received and practised by other bodies of Christians as non-essential. "There are two ceremonies in use amongst most professors of the Christian name,—water baptism, and what is termed the Lord's Supper. The first of these is generally considered as the essential means of initiation into the church of Christ, and the latter of maintaining communion with him. But as we have been convinced that nothing short of his redeeming power, inwardly revealed, can set the soul free from the thraldom of sin, by this power alone we believe salvation to be effected. We hold, that as there is one Lord and one faith (Eph. iv. 5), so his baptism is one in nature and operation; that nothing short of it can make us living members of his mystical body; and that the baptism of water, administered by his forerunner John, belonged, as the latter confessed, to an inferior and decreasing dispensation (John iii. 30). With respect to the other rite, we believe that communion between Christ and his church is not maintained by that nor by any other external performance, but only by a real participation in his divine nature (2 Pet. i. 4) through faith; that is the supper alluded to in the Revelations (Rev. iii. 20), 'Behold I stand at the door and knock; if any man hear my voice, and open the door, I will come in to him, and sup with him, and he with me;' and that where the substance is attained, it is unnecessary to attend to the shadow, which doth not confer grace, and concerning which opinions so different, and animosities so violent, have arisen."

6*th.* Their great doctrine of the inward light necessarily implies the doctrine of repentance and a new life; in the words of Penn, "Repentance from dead works to serve the living God, which comprehends three operations:—*First*, a sight of sin; *secondly*, a sense and godly sorrow for sin; *thirdly*, an amendment for the time to come. This was the repentance they (the first Quakers) preached and pressed, and a natural result of the principle they turned all people unto."[1]

7*th.* "From hence sprung another doctrine which they were led to declare. Perfection from sin, according to the Scriptures of truth, which testify it to be the end of Christ's coming, and the nature of his kingdom, and for which his Spirit was and is given,—viz., to be perfect as our heavenly Father is perfect, and holy because God is holy. . . . . But they never held a perfection of wisdom and glory in this life, or from natural infirmities, or death, as some have, with a weak and ill mind imagined and insinuated against them."[2]

Such are the great and strictly religious doctrines of the Society of Friends. There are others which they hold in common with other Christians, and which need not be enumerated here; but there are others, again, constituting a great system of philosophy, of morals, and manners, which distinguished the faith of George Fox from that of his predecessors and contemporaries, and which, if permitted to operate freely throughout society, would unquestionably produce the most amazing and beneficent changes. In the gospel declarations, that "God made of one blood all the nations of the earth," and that "he is no respecter of persons," he perceived nothing less than a charter of the most perfect freedom and equality of right to the whole human race. He carried out this idea so liberally, that he extended it to the female part of the community. He declared the equality of the sexes; that there is no sex in souls, but all are one in Christ Jesus; and on this ground he gave the female Friends a participation in the civil economy of the society. He extended this doctrine to all nations and colours; one right and one law for all men, whether white or black. In the declaration of Christ the heathen lorded it over one another, but it should not be so amongst his disciples, where he saw the law of brotherhood, and not of subjection. This law once recognised, he could no longer recognise the contrary law of bloodshed and revenge; he was bound to pronounce the anti-Christianity of war. He pronounced the anti-Christianity of all oaths, on the clear and unequivocal command of Christ, "Swear not at all."

[2] Ibid., p. 19.

Peculiar customs and practices.

He regarded Christianity as a heavenly dispensation, sent down to draw us from the follies and vanities of the world, and the very essence of which consisted in a renewed vitality of mind. This led him to resist, despise, and expose those assumptions of absurd titles, those demands of servile obeisance and empty flatteries by mere wealth and factitious rank, which degrade both givers and receivers, and fill the world with so much misery and heart-burnings, so much meanness and pride. On this principle, he adopted the utmost simplicity of dress and manners. He resumed the original use of *thee* and *thou* to a single person, the more so as *you* was then used to a rich person, and *thou* to a poor one. He abandoned the practice of what he called "hat-homage," taking off the hat, and bowing, as marks of obeisance to superiors. He refused to address persons of rank by the titles of your Majesty, your Excellency, your Grace, &c., looking upon it as the basest flattery, where there happened to be neither majesty, excellency, nor grace. Believing in the authenticity of no ministry but such as depended alone upon the teaching of the Holy Ghost, he denied the right to tithes, church-rates, or any compulsory payments to the support of a priesthood. As he regarded the ceremony of marriage as requiring for its celebration no interference of a minister of the gospel, he refused the mode adopted at the altars of the Established Church, and introduced a simple form of marriage in the meetings of his own society. He rejected the common customs of mourning and burial, as not being in accordance with the simplicity of the gospel. Regarding the names of the months and days of the week as originating in mythological idolatry, he substituted a mere numerical nomenclature. Various practices and social indulgences, as singing, dancing, music, the frequenting of theatres and other places of public amusement, playing at games of chance for money, drinking of healths, horse-racing, and field-sports, were renounced and discouraged by him, as incurring waste of time, or as inconsistent with the serious hopes and duties of Christians. These innovations were all adopted by the Society of Friends, and became fixed rules of practice.

The first preachers among the Friends.

It is obvious that a system like this could not be promulgated without setting in array against it an innumerable host of enemies. There was scarcely a custom of society, or a profession in it, at which it did not aim a severe blow. The church, the army, the law, each felt that it was menaced with decay or change. Royalty saw that if this doctrine succeeded, it would lop off the right arm of arbitrary power, for it could not flatter the divine right of kings. The clergy saw that it did not object to this or that dogma, this or that ceremony, like the Puritans, but it assailed, root and branch, state religion itself. If Quakerism succeeded, where would be the soldier and the marine; where the gainful trade of litigation? It was a system which aimed a death-blow at the flatteries of the world, and the self-gratulation and self-indulgent spirit of human nature; and it was accordingly speedily saluted with one general and furious tempest of hatred and vengeance. But, before turning to the persecutions of the Quakers, we must first notice the singular zeal, and as singular enterprises, of their first ministers. It has been stated that in the seventh year of Quakerism these ministers amounted to upwards of sixty. These numbers continued for some years to increase rapidly; and they were animated with a surprising spirit of proselytism. Of these, Francis Howgill, John Audland, Samuel Fisher, had been clergymen; George Bishop, Richard Hubberthorn, William Ames, officers in the army; Anthony Pearson, John Crook, justices of peace. Of the rest, Edward Burrough, Robert Farnsworth, James Nayler, William Dewsbury, John Camm, Thomas Lowe, William Caton, and James Parnel, were amongst the most eminent. William Penn and Robert Barclay, two of their most celebrated members, did not join the society till about twenty years after its formation. There was also a considerable number of women-preachers, who displayed a spirit as bold and zealous as the men.

Firmly persuaded that they were actuated by the immediate influence and revelation of the Divine Spirit, and ordained to restore the primitive form and simplicity of the Christian faith, the Quaker preachers traversed every quarter of the United Kingdom, entering the churches of the establishment, denouncing their ceremonies and doctrines, telling the people that they were come to call them off from such things, from "the beggarly elements" of outward observances and outward teachers, to the great Inward Teacher; that the ground on which these churches stood was no more holy than any other ground;[1] and that sprinkling with water, putting on of surplices, and repeating ready-made prayers, were but relics of Popery. As these clergy and churches were maintained by the nation, they conceived that they had the clearest right to call upon the nation to look into them. They did not stop here; they believed it their duty to address solemn warnings to magistrates, to Parliament, to the protector or the king as it might be, and what they regarded as their duty to the public. George Fox, Edward Burrough, Samuel Fisher, George Whitehead, and others of the Friends, had repeated interviews with Cromwell, Charles II., and other monarchs; and William Penn was a regular visitor at court during the short reign of James II.[2] Many of the preachers extended their travels to France, Germany, Holland, and America. George Fox himself visited Holland, America, and the West Indies. Penn and Barclay visited Holland and Germany, and were received with the most cordial sympathy by Elizabeth, the princess of the palatinate, who entered into a religious correspondence with them.

Their zeal and singular actions.

Their success, and perhaps the very heat and opposition of the times, so stimulated their zeal and confirmed their opinions, that they now declared that they moved in the same spirit and power as the apostles. George Fox declared them little better than imposters who did not possess and act in that power and spirit. He believed that by the Inward Light, not only the Scriptures, but both the intellectual and physical world, were opened to him. "He knew not only a renewing of the heart, and a restoration of the mind, but the *virtues of the creatures were also opened to him;* so that he began to deliberate whether he should practise physic for the good of mankind. . . . . The three great professions in the world, physic, divinity and law, were opened to him," &c.[3] He worked miracles, according to his own testimony and that of his friends. He cured a woman of a distracted mind, by merely telling her, in the name of the Lord, to be quiet.[4] He commanded a man at Arn-side to stretch out his withered arm, and it was restored.[5] But he believed himself not only endowed with the apostolic, but with the prophetic power. He foretold to Judge Fell, a fortnight before anybody else dreamed of such a thing, the dissolution of the Parliament by force.[1] He had a vision of an angel with a fiery sword, prophetic of the great fire in London.[2] Meeting Cromwell riding in Hampton Court Park, as he drew near, "he perceived a waft of death go forth from him." Cromwell invited him to come to the palace, but on going the next day he found him already on his death-bed.[3] He exercised the same gift on many other occasions, foretelling judgments on his persecutors. His coadjutors laid claim to the same revelations. They were zealous to the last to address warnings to magistrates and to governments; as Francis Howgill to Cromwell;[4] Samuel Fisher to the Parliament;[5] Edward Burrough to Cromwell and his council, &c.[6] They foretold events. Thomas Aldam foretold the fall of Cromwell;[7] George Bishop, the great plague in London;[8] Thomas Ibbitt, Humphry Smith, George Fox the younger, and Thomas Briggs, the great fire of London;[9] Edward Burrough, the death of Cromwell, his own death, and various other events.[10] They exhibited signs, like the ancient prophets. A woman went into the Parliament in 1658, with a pitcher in her hand, and breaking it, told them, so should they be broken to pieces.[11] Thomas Aldam took off his cap before the Protector, and tearing it to pieces, said, "so shall the government be rent from thee and thy house."[12] In 1660 Robert Huntingdon went into the church at Brough, near Carlisle, wrapped in a white sheet, and with a halter about his neck, to show the Independents and Presbyterians that the surplice would be introduced again, and that some of them would be hanged.[13] A woman appeared in a Protestant church at Dieppe, in sackcloth and ashes.[14] Thomas Ibbitt, two days before the fire of London, dismounted from his horse with his clothes hanging loosely about him, as though he had come in great haste, and went about the city denouncing judgment.[15] Solomon Eccles went into a Catholic chapel at Galway in Ireland, and when the people were on their knees, appeared naked above his waist, with a chafing-dish of coals and burning brimstone on his head, and, crying "Woe to these idolatrous worshippers," declared that God had sent him to show them their portion, unless they repented. The same man went into a church in Aldermanbury in 1659, and seating himself on the pulpit-cushion, in the face of the audience, began to sew.[16] In 1662 Daniel Baker, being in a ship becalmed opposite to Gibraltar, went ashore on Maunday Thursday, proceeded to the mass-house, and amid the people at high mass he rent his clothes, discovering sackcloth on his body; then taking his hat from his head, he threw it on the ground and stamped on it, and calling on them to repent, so passed away.[17]

Zeal of the first Quakers.

But the zeal of the first Quakers could not expend itself even in these extraordinary demonstrations; many of them set out to the very ends of the earth, with what they believed to be commissions from on high. One young woman, Mary Fisher, proceeded to Adrianople (although once stopped at Venice, and sent back by the British consul) to convert the Grand Turk, who received her in the most courteous manner.[18] Two others, Catharine Evans and Sarah Cheevers, went to Malta to reclaim the Catholic inhabitants, but did not meet with so handsome a reception as their sister had done from the Sultan. They were clapped into the prison of the Inquisition, and only liberated after a four years' imprisonment, through the interference of Lord D'Aubigny.[19] John Love, John Perrot, Samuel Fisher, and John Stubbs went to Rome, to testify, in the presence of the Pope and cardinals, against their superstitions. Love died in the Inquisition, but the others escaped.[20] George Robinson travelled to Jerusalem to denounce the trade which the friars made of the holy sepulchre, and to convert the Mohammedans, and also returned safe.[21] Others crossed to New England, where we shall have occasion to speak of them immediately.[22]

Persecutions suffered by the Friends

The persecutions which the Friends suffered forms another remarkable chapter in their history, and one in which they appear to great advantage. We have seen what were their doctrines, and that their promulgation was sure to plunge them into a sea of suffering. This was soon verified. Wherever they appeared, the clergy, who justly looked upon them as the most daring and determined enemies that ever appeared against them (for they everywhere declared to the people that their system was anti-Christian, and rotten to the very core), on all hands roused the civil and military powers against them. Wherever they preached they were hauled before the magistrates, fined or imprisoned; but though the persecution waxed hotter and fiercer every day, they never for a moment flinched, or remitted their activity in travelling and preaching all over the country. No persecution in modern times fell more heavily or savagely upon any people; and it must be said, to the honour of the society, that no people ever stood up more firmly for the rights of conscience and the liberty of the subject. The trials of the Friends, and especially that of John Crook in 1662,[23] and that of William Penn and William Mead in 1670,[24] at the Old Bailey, will for ever remain as noble monuments of their resistance to the arbitrary proceedings of the courts of judicature at that time, and their violent infringement of the privilege of jury. In the latter case there happened to be a noble jury, who, insensible to the most atrocious attempts made by the court to force a verdict, were shut up without "meat, drink, fire, or tobacco," for two nights and a day, and, still remaining immoveable, were conveyed with the prisoners to Newgate.

The enemies of the Quakers were furnished with abundant means of oppression, in the various acts which had been passed since the days of Henry VIII. till then, against the Popish recusants, and otherwise, to compel conformity to the Established Church. There was the 27th of Henry VIII.; the 1st of Elizabeth, for twelvepence a day; the 5th of Eliz. *De Excommunicato capiendo;* the 35th of Elizabeth, for abjuring the realm, on pain of death; the 3d of James I. for præmunire, imprisonment for life, and confiscation of estate; the 13th and 14th of Charles II. for transporting Quakers; the 17th of Charles II. against Nonconformists; the 22d of Charles II. against seditious conventicles. They were so surrounded with snares that there existed not a chance of escape if there were the slightest desire to punish them. If all charges against them failed on any occasion, there was the oath of allegiance and supremacy always ready to present to them; and the Quakers could not take any oath whatever. But by the last act against conventicles, passed in 1670, they were completely given up as a prey to the informers. Any five persons convicted of being present in one house, over and above the ordinary family, were to be fined five shillings for the first offence, ten for a second, twenty pounds for preaching, forty for a second offence, and twenty pounds for the building in which the meeting was held, the whole to be levied by distress; and if any one person could not pay his fine, it was to be levied on any one or more who could, the informer receiving one-third of the amount. Under such temptations to low cupidity, loss of their property and imprisonment of their persons spread throughout the whole country. Cromwell and Charles II. both professed a desire to stay this persecution, but they took few measures to effect this object; on the contrary, during the whole reign of Charles persecution raged more and more vehemently. Their sufferings lasted thirty years, and the simple matter-of-fact relation of them fills two large folio volumes of more than one thousand four hundred closely-printed pages. The prisons were full of them, and these prisons were pestilential dungeons, of which we can now hardly credit the description. In them there were at one time 4200 Quakers. The prisons of London had suffocating crowds in them, and the celebrated HOLE in Newgate was the death of numbers. Ellwood, the friend of Milton, and who had the honour to suggest the composition of *Paradise Regained*, was in Newgate amongst these numbers, and has left us, in his Life, some curious sketches of those scenes. The majority of the first preachers of Quakerism died in prison. In 1662 twenty Friends died in the London jails; in 1664 twenty-five more; in 1665 fifty-two others, besides seven who died after liberation, in consequence of their treatment during confinement. According to Besse, the historian of their sufferings, the total number of Friends who perished in prison during this period was 369. In Bristol at one time every adult was in prison. In London in 1670 Charles issued an order, signed by the Archbishop of Canterbury and thirteen others, commanding Mr Christopher Wren to pull down their meeting-houses at Ratcliffe and Horsleydown, which was done, and the materials sold. Peel meeting-house was ransacked, and stripped of doors and windows. Their other meeting-houses were nailed up; and the Friends, who met on the ruins, or in the street, were driven away by soldiers, mercilessly beaten with the butt-ends of their muskets, and some of them killed. Throughout the severe winter of 1683, these steadfast people collected in the streets to worship, in spite of all pains and penalties, and suffered incredible hardships and insults. The dead were disinterred from their graves; women and children were dragged by the hair along the streets; some were pricked with needles and bodkins, and others were sold to the sugar plantations. Meantime their property was at the mercy of constables and informers, who wrenched open their doors with sledge-hammers and screws, and carried off everything, to the very children's food, often leaving not a tool to work with, or a horse to plough the land. In many instances these fellows, where the men were in prison, carried the keys of their houses in their pockets, went in and out as they pleased, declaring that they would "eat of the best and drink of the sweetest, and these rogues of Quakers should pay for all." There was levied at one time on the Friends at Bristol, for fines, L.16,400; and, from a careful examination of the records of the society, it clearly appears that property was taken or destroyed at that period to the amount of upwards of one million sterling.

[24] *State Trials*, vi. 951; Sewel, ii. 259; Gough, ii. 328.

This sketch of their persecutions would not be perfect if we omitted their treatment in New England. There, the colony of Independents, whose history is so well known from the circumstance of their having fled from persecution at home, and immediately become persecutors themselves, and whose cruelties to the Indians and to one another form so gloomy a passage in history, no sooner heard that two Quaker women were arrived in the harbour, than they seized on them before they could land, put them in prison, stripped them naked, and barbarously treated them. They ordered three other Quaker women to be stripped to the waist, and flogged through eleven towns, a distance of eighty miles, in all the severity of frost and snow. They then hanged three men and one woman, before a mandate from the king could arrest their bloody course.

The extent of persecution was much diminished by William Penn opening an asylum for his friends in his new state of Pennsylvania, whither great numbers emigrated; and a final stop was put to them by James II. He permitted the Friends to substitute an affirmation instead of an oath; then came the Toleration Act of William II., recognising more fully the rights of conscience; and subsequent acts legalized their marriages, and placed them at ease amongst their fellow-citizens. They still continued their conscientious refusal to pay tithes and church-rates, and these are taken by distraint, to the average annual amount of about L.11,000.

It would give an unfair view of the Society of Friends, if, after exhibiting the vehemence of their early zeal, we did not remind the reader of the peculiar spirit and circumstances of that age. Then all the elements of political and religious unrest were in a state of chaotic turbulence, and the whole style of language and of action amongst all denominations was such as would now be pronounced violent and fanatical. The Quakers, in this respect, only partook of the spirit of the age; and to understand them more truly, we must see them in their patient steadfastness under their dreadful misusage, in which they gave the highest evidence of the influence and support of the Divine Spirit. It is to their everlasting honour that they never showed the least symptom of retaliation. Though often urged, when circumstances were in their favour, to denounce their enemies, they had on all such occasions but one answer, "We leave them to the Lord." They not only went on steadily, preaching and convincing thousands, but they set about and organized a system of discipline or church-government, distinguished in a remarkable degree for its order and decorum. In the first place, they established a standing committee in London, called "The Meeting for Sufferings," for receiving the earliest accounts of the persecutions of their friends from all parts of the kingdom, and for taking the promptest measures for their mitigation. It was in this committee that George Fox was to be constantly found to the latest day of his life, whenever in London, anxiously engaged in endeavouring to alleviate the sufferings of the society. The system of discipline then organized, and which continues, in the main, as it was left by the first Quakers, we have now to describe.

Discipline of the society.

Wherever the Friends have a meeting-house, they hold, once a month, after the meeting for worship is over, a meeting for discipline; or, in other words, for all the civil and ecclesiastical affairs of the body. Though they do not pay their ministers, they deem it right to defray their expenses when they travel in the ministry. They hold it a Christian duty to support their own poor, and to educate their children. For these purposes they raise the necessary funds by voluntary contribution at these meetings, which are called Preparative Meetings; that is, meetings preparatory to the monthly meetings, which include several preparative meetings. Each preparative meeting appoints representatives to attend the monthly meeting.

The monthly meeting receives the funds for the poor, and appropriates to each meeting what is necessary. It also receives the funds for the public schools, and for what is called "the National Stock;" that is, a fund placed at the disposal of the society at large for general charges; and hands them in by its representatives to the quarterly meeting. In these monthly meetings is chiefly vested the real property of the society, as its meeting-houses, lands, &c. They judge of the fitness of persons applying for membership, excite to due attention to religious and moral duties; and deal with disorderly members. They grant certificates of membership and conduct to those removing into other monthly meetings, without which they could not be received as members. They appoint two or more persons in each particular meeting, called overseers, to watch over the general conduct of the members, maintain the decorum of the meeting, and see the discipline enforced. They appoint also two or more persons, of high religious standing, as elders, to watch over the ministry, to judge of the fitness of such as offer themselves as preachers, and to sympathize with those already acknowledged. It is contrary to the rules of the society for any of its members to go to law with each other; all differences are to be settled by arbitration; and it is the duty of the monthly meetings to deal with such as violate this rule. Parties wishing to marry appear at these meetings and declare their intention; persons are appointed to inquire whether the parties are free from other engagements, and whether they have the consent of parents or guardians. These inquiries being answered in the affirmative, and the parties signifying to the following monthly meeting their continuance in the same mind, are permitted by it to proceed.

Several of these monthly meetings compose a quarterly meeting. A quarterly meeting, indeed, generally embraces one or two counties. At the quarterly meetings are produced, from the monthly meetings, written answers to certain standing queries respecting the conduct of the members, and the meetings' care over them. These accounts are digested into one, and sent on by representatives to the yearly meeting. The money contributions for the national stock, &c., are not forwarded by the representatives from the quarterly meetings to the yearly meeting directly, but by appointed correspondents in each quarterly meeting to the Meeting for Sufferings, which is the fiscal and executive organ of the yearly meeting. Ministers wishing to travel in the ministry in Great Britain must obtain a certificate from their own monthly meeting; and if they extend their views to Ireland, they must take one from the quarterly meeting. The quarterly meetings assist their monthly meetings in difficult cases, and hear any appeals from their judgment.

From the quarterly meetings in spring, representatives are sent to the yearly meeting in London; thus the affairs of the society coming into operation in every meeting in the kingdom, gradually concentrating themselves into one focus, concerns of a local nature being dropped in their own proper sphere, and the monthly or quarterly meetings, and those of a more general interest being carried on to the great annual assembly. To understand, however, the mechanism of the society, it must be explained that these meetings of discipline, monthly, quarterly, and yearly, are not restricted to the representatives only. All members may, and great numbers do, attend them; for not only has every member a right to give an opinion on all public questions, but these meetings offer points of pleasant reunion and acquaintanceship. It must, too, be understood that the women, simultaneously with the men, but in a separate apartment, hold their own monthly, quarterly, and yearly meetings of discipline, in which they watch over the interests, the moral conduct, and the religious consistency of the female portion of the community. There is also, previous to any meeting of discipline, a meeting of ministers and elders, to strengthen each others' hands. To their meeting in London, more commonly called "the Morning Meeting," is intrusted the revision of manuscripts which concern the principles of the society, and the granting of certificates to ministers wishing to travel abroad during the intervals of the yearly meeting. These ministers and elders afterwards take their places in the general meetings of discipline. The ministers are also members of the Meeting for Sufferings, which, as already stated, is the standing committee of the society.

These subordinate and preliminary meetings, then, having been held, the yearly meeting comes on in London in the month of May. There is but one yearly meeting for these united kingdoms, to which come representatives from Scotland and Ireland. But in America, where the great body of the Quakers is now to be found, there are eight yearly meetings, which correspond with the English yearly meeting, and with one another; besides five yearly meetings of what are called Liberal or Hicksite Quakers, with whom neither the English nor the other American Quakers hold any communication. The discipline in all is pretty much the same, and therefore the description of that in London may represent the rest. It elects a clerk, who officiates at once as chairman and secretary, and an assistant-clerk, to relieve him by reading long documents, &c. The meeting is held by adjournment from day to day, and generally continues about ten days. It receives epistles from Friends in Ireland, and the orthodox yearly meetings in America, and appoints committees to draw up answers. It receives and considers the answers to the standing queries on the moral and religious condition of the society, from all the quarterly meetings. Accounts are laid before it by the Meeting for Sufferings of all the seizures for tithes, church-rates, &c. It has committees sitting on the state of the public schools, on the subject of slavery, and on other questions, in which the Friends take great interest, and on which they frequently feel bound to address the crown, petition Parliament, or call upon the public for its attention. It has a committee to receive all appeals against the decision of the quarterly meetings. It alone has power to alter any of the established rules of the society, or to make new ones. It sometimes appoints committees to visit such quarterly meetings as appear in need of help; and it always addresses a general epistle to the society, which is read in every meeting in the kingdom; the women Friends issuing an epistle from their meeting, addressed to the female community exclusively.[1]

Peculiar mode of worship.

In their mode of worship the Friends differ from all other Christians. Believing all worship to depend upon the immediate operation of the Holy Spirit, and having therefore no paid ministers, no stated prayers, no singing even, they walk into their meeting-house, the men with their hats on, and sit down in silence. They keep on their hats because they do not believe that place to be holier than any other, or that worship is more acceptable at one time than another, but that it is enjoined on us and is good for us, to assemble ourselves together before God. They have no separate pews, but all the men sit together on one row of benches, and all the women on another. They have no pulpit, because they have no fixed preacher; but as they may have several voluntary ones, they have a long raised gallery in front of the congregation, where the ministers sit, the men facing the men, and the women facing the women of the audience. The elders sit with them or with the overseers, in a lower gallery, still facing the meeting. As the ministry is independent of human appointment, so is it of human choice in its distribution. There may be, and often are, half a dozen ministers or more resident, as in large towns, and there may be a succession of sermons and prayers, whilst in great numbers of other meetings there is no minister, nor a word spoken for years together, except it be by travelling ministers, who occasionally visit, not only their meetings, but each family belonging to them.

---

[1] For all that relates to the civil and religious economy of the society, see its statute-book, *The Book of the Rules of Discipline*, &c.

Great change in the character of the society.

Such were the early Quakers, and such are the forms of polity and worship which they have left behind them. Those who now see the Friends as they are would scarcely believe them to be descended from so fiery and innovating a race. The old Quakers were vehement in the promulgation of their principles, and aggressive in their attacks on the principles of others. The present Friends neither assail the religious doctrines of others, nor seem anxious to diffuse their own. The virtue of the first Quakers was active, that of the present is passive to a miracle. They cling tenaciously to the outward forms of their system, and to their peculiarities of dress, speech, and renunciation of popular amusements; but the ancient fire which once lit up their body seems to have gone out. They profess to hold their great principles as sacred as their ancestors did, but they show little anxiety to make them known. Much of this remarkable change is plainly attributable to natural causes. The violence of a religious paroxysm determines the length of its duration. When persecution ceased, the Friends found themselves thrown, by their abandonment of the ordinary amusements and tastes of the world, on trade for occupation, and led home for relaxation. They became busy, domestic, and of consequence wealthy. These causes will explain much, but there is another cause which will explain more of the present circumstances of the society; their great tenet, and corner-stone of their faith, the Inward Light. Carrying this doctrine to the extent which they do, that it is the all-sufficient guide; that its guidance is to be sought and waited for; that we must put down before it our own imaginations and reason, and without its impulse we must make no religious movement, it has had this effect; it has acted as a blight upon the ministry. Those who might feel disposed to address their meetings from a simple feeling of love, and desire for the salvation of their fellows, and from a belief that every good motive must come from the source of all good, and would be blessed by Him; these, perhaps the most able members of the body, have yet shrunk from the task, because they felt that they should be restrained by the elders, as persons running in their own strength, and in their own natural reason. Those who have not been so sensitive, and have been adopted as ministers, have entered upon a process of putting down every motion and faculty of their own minds, and of waiting for a direct and palpable revelation from heaven. The consequence need not be stated. It is a fact, that since the first days of Quakerism they have had few preachers of extraordinary eloquence or originality of mind. The ministry is now confessedly low, and the sermons heard in their meetings are most frequently commonplace and rambling. The experiment of an unpaid ministry in their hands has been by no means a splendid one. No spread or prevalence of their doctrines has followed, at all answerable to the ground of inspiration assumed. With the exception of two preachers who have lately paid a visit to Australia and the South Sea Islands, they have sent out no missionaries, nor contributed to the funds of those societies which did, because they were not moved to it; as if the evidence of success were not sufficient warrant. In their meetings of discipline the same principle has produced the same effects. Though all profess to live under the influence of the spiritual guide, some are supposed to live under it more habitually. These have acquired the name of Weighty Friends, that is, Friends of weight of character and consequent influence. Instead, therefore, of deciding all questions in these meetings by the ordinary mode of voting, or by a show of hands, a mode, one would have imagined, particularly consonant to their views of natural right, they have adopted the singular one of deciding by weight; that is, by the dicta of the Weighty Friends, who for the most part are men of weighty purses too. These Friends have only to say, "I am of this or that opinion," without assigning any reason, and this is taken as the sense of the meeting, and decides the question. Thus is the government of the society thrown into the hands of an oligarchy of the most dangerous kind; for none can be more dangerous than that of an assumed sanctity; and thus are the advantages of their otherwise popular system curiously neutralized.

The same principle has operated still further. It has damped religious inquiry and discussion. In the common affairs of life and trade, where the Friends have used their understandings, they have shown themselves shrewd and successful; in matters of religion they thought it right to renounce their natural faculties, and wait. When the young have expressed to ministers, or any of their elder Friends, their doubts or uneasiness on any religious point, they have replied, "they did not feel free to discuss such matters;" they advised them to "centre down into their own minds, to turn inward to the infallible guide." The consequence became apparent in a dearth of religious intelligence. There was not the same inquiry into and clear recognition of religious doctrines amongst them as amongst other communities of Christians; and when the spirit of research burst upon them from without they were startled. Many felt themselves like mere children in theology, and were scattered different ways.

Modern schisms among the Friends.

These divisions first showed themselves in America in 1827. They originated in objections to the doctrines of a very popular and aged minister, Elias Hicks; but at the yearly meeting in Philadelphia that year, it was found that great numbers were of his opinions, and the parties came to an open rupture. The schism soon spread to New York, and the feud raged for some years with great violence, ending eventually in the total disruption of the society in America. It is difficult to state the numbers of the society, because there has always been a reluctance to take a regular census of the body. In the year 1659, from the number of females who signed petitions to Parliament, it was calculated that the number altogether in England was about 30,000. At present, from calculations made by private individuals, there does not appear to be quite 20,000; but in America they have been variously estimated at from 100,000 to 160,000, and may be very safely rated at more than 100,000. The section of the American Quakers calling themselves orthodox state the numbers who avowed the opinions of Elias Hicks at 30,000; the Hicksites themselves claim 60,000. It may therefore be fairly taken for granted that the body there is pretty equally rent in two. The English Quakers renounced the Hicksite Quakers, though these people protested that they held, and had always held, the doctrines of the first Friends in their integrity. Scarcely was this schism effected when the Quakers in England found themselves assailed on the opposite side by a party which had been most urgent with them to disown the Hicksites. This attack appeared in the shape of a publication called *A Beacon to the Society of Friends*, warning them against the errors of Hicks, and advocating water-baptism, the taking of the Lord's Supper, and other opinions which the Quakers from the first had abandoned. The heats and contentions incident to religious disputes have, on this ground, distracted the society here; some few have withdrawn from the body, and several individuals have been dismissed for adopting ceremonies which Quakerism rejects; but the body itself has hitherto remained entire. It is not necessary here to enter into the points in dispute. It may suffice to say, that the Hicksites are charged with setting the Inward Light above the Scriptures, and the Beaconites with setting the Scriptures above the Inward Light; the Hicksites with running too far into mysticism, and the Beaconites into the "beggarly elements" of outward form. Both parties appeal to Scripture against each other, and the English Friends appeal to it against them both. The circumstance to be regretted is, that this society, which has boasted that it "has no creed," and which says, "We require no formal subscription to any articles, either as to the condition of membership, or to qualify for the services of the church; we prefer judging of men by their fruits;" should thus rend itself to pieces about "articles of faith," and the very stuff of which "creeds" are made.

Their high philanthropic character.

If, however, the Society of Friends, having an "infallible guide," has not avoided wandering different ways; if, being "a Society of Friends," they have not avoided bickerings and divisions; they have the honour of being amongst the noblest and most unwearied philanthropists which the world has ever seen. In this character they have proudly maintained their testimonies. If George Fox was not untouched with the extravagances of his age, he outstripped that age two hundred years in his clear perception of the highest requirements of Christianity. He was amongst the first, if not the first, to call public attention to the dreadful state of our prisons, to the injustice of capital punishments for mere stealing, and to the atrocious system of confining fresh prisoners with the most thoroughly debased.[1] He declared the anti-christianity of war, oaths, and slavery. In the maintenance of all these great truths, to the recognition of which the world is now but tardily coming, his followers have nobly emulated him. William Penn, by his just treatment of the Indians, and the full liberty of conscience granted in his new state of Pennsylvania, showed the noble lessons he had learned in this school. It was amongst the Friends that the great crusade against Negro slavery commenced in the person of John Woolman, an American minister.[2] From that time to the present the Quakers have never ceased their efforts in that cause. They were the first in England to form an association for the abolition of the slave-trade. Thomas Clarkson, on setting out on his career, found them everywhere ready to co-operate with him, and to the last day of the struggle their purses and personal exertions were never spared. They have not been less zealous in spreading their opinions of the crime and impolicy of war; and in prison discipline Elizabeth Pryor, a name not enough known or honoured, and her more known but not more deserving coadjutor Elizabeth Fry, have merited largely of the public. It is in this point of view, in thus early and steadily, theoretically and practically, exhibiting Christianity in its highest and most beneficent form, "peace on earth and good-will towards men," that the Friends have conferred on society the greatest good of which men can be made the instruments, and deserve from it the most grateful esteem.

Since the first publication of this article, a great change has been going on in the Society of Friends in regard to some of the things to which George Fox and the early Friends objected, and also as regarded certain "testimonies," as they were called, which had originated with the first Friends, or had gradually developed themselves in supposed accordance with the principles of the society. There are certain arts and practices which have nothing evil in themselves, but, on the contrary, are highly esteemed by mankind in general, as having a refining and elevating tendency, which George Fox discouraged the practice of, on the plea that they led to gross abuses, to undesirable associations, or were consumptive of time which might be better employed. Under the host of things to be avoided on such grounds were the fine arts, painting, sculpture, music, singing, and dancing. The fine arts were objected to both because they were, in Fox's time, too frequently employed on meretricious subjects, and to flatter the worst tastes and habits of society. They were made to flatter grossly the mere worldly great, and to perpetuate characters which were better buried in oblivion. Fox thought the only mode of protecting his followers against the pernicious influence of arts so employed was to forbid them altogether. Friends were neither allowed to practise these abused and degraded arts, nor to embellish their houses with specimens even of their better kind, as leading only to a love of the merely ornamental, and to a costly display which fostered ostentation. To adorn their houses with paintings and sculpture was inconsistent with that simplicity of life, and that religious tone of mind, which the Friends were called upon to cultivate in opposition to the spirit of the world.

The objection to painting and sculpture, on account of their abuse, applied still more strongly to music, singing, and dancing. These at that time were too redolent of the sensuous, the frivolous, the false, and the dissipated, to be admitted into the houses of Friends. They led, moreover, directly to worldly acquaintanceships, worldly pleasures, and a worldly tone; to assemblies, theatres, operas, concerts, and parties where mere amusement, at the cost of seriousness and propriety, was the prevalent feature. The Friends regarded, moreover, the years of youth which are requisite to acquire proficiency in painting, music, and the merely elegant accomplishments, as a serious absorption of a period when more solid acquirements demanded almost the whole attention; besides, it was not a singing and piping age to the Friends, but an age of contempt, persecutions, prisons, and tribulations.

Such, then, were the principles and circumstances which shaped and coloured the life of Quakerism, and left their results fixed till a recent period; but during this recent period the members of the society have gradually emerged more familiarly into the intercourse of life at large. They were become wealthy, well-educated, and esteemed for their high moral character. They were come in contact with, in the prosecution of great aims, Bible societies, anti-slavery societies, societies for promoting education and other similar objects; and when, by the acceptance of their affirmation instead of on oath, they were admissible to the magistracy and to Parliament, their intercourse with the best society became more extended.

Under these influences, and under the influence of a very marked and progressive improvement in the public taste as it regarded the fine arts, and consequently from the high moral qualities required as works of art, Friends began to see that the rejection of a good thing on account of its popular abuse was by no means a sound practice; that it became good, intelligent, and independent people to support the moral and religious progress of the arts by adding their own moral momentum, the purifying force of the countenance of the virtuous, to the patronage of what was eminently good in itself. They came, therefore, more and more to recognise what was ameliorating and beneficial to human life in the fine arts; and of late years every one must have remarked the numbers of Friends, especially at the time of the yearly meetings, who have crowded our galleries of painting and sculpture. A considerable number of them became purchasers of good pictures having a high moral purpose. You find such works beginning to embellish their walls, and their children have been carefully educated in drawing, and a taste for it. Though we are not aware of any distinguished painter who is a member of the society, they have distinguished engravers and photographers; and their admiration of fine works of art is now become general. Music is cultivated in a great number of Friends' families: they have an amateur singing society, and it is by no means an uncommon sight to see in the houses of grave Friends young people engaged in the dance.

[1] Sewel, i. 67; Fox's *Journal*, i. 143.

[2] *Journal of John Woolman*; also Woolman's *Considerations on the Keeping of Negroes*, Philadelphia, 1754; Dublin, 1776.

Coincident with these social phenomena have appeared, from the same cause, the growth of more liberal ideas in the society, amalgamating with the more moral sentiment of the age in general, other relaxations of the ancient rigour of Quakerism. This rigour had been especially maintained in regard to marriage. They regarded the marriage of one of their members to a person belonging to the world at large, or to another religious body, as leading to many and serious evils,—those of a divided household, divided on the most momentous question, that of religious faith. This unequal yoking they beheld with peculiar repugnance, from its necessary effect on the minds of the children of such marriages, who must grow up under the distracting effects of a diversity of faith in the parents, and in being pulled two ways in attendance on different forms of worship. To discourage such marriages, they did not allow any one to be married at their meetings to one of their members who was not himself or herself a member, although this person might attend their meetings and hold their religious opinions; nor could such a couple be married by a priest, because the Friends had a decided testimony against a "hireling ministry;" and for a Friend to be married by such a minister would constitute a breach of the fundamental principles of the society. All such offenders, unless they took the precaution previously to resign their membership, were disowned,—that is, expelled from membership,—by the society. By this rigour the Friends actually branded a law of nature as an unchristian offence; nor did they relax this rigour when the parties, instead of going to a "hireling minister," could go to a magistrate.

But the quarterly meeting of Yorkshire, taking the start in a more rational view of things, brought a proposition to the yearly meeting in May 1856, suggesting that these rules respecting marriage should be abolished, and marriages allowed betwixt a member of the society, and one not in the society, but professing with it; or even betwixt two persons neither of whom should be a member, but both of whom should attend the meetings of the society and profess its principles; and that these marriages should be solemnized in the manner and in the meetings of Friends.

This bold proposition naturally took the more advanced in age and orthodoxy by surprise. The proposition was warmly debated at that and the succeeding yearly meetings of 1857 and 1858, and by the last was referred for decision to a conference of three hundred members, which met in London on the 2d of November 1858, and by which the proposition was fully acceded to.

But before this conference was brought another question, also marking a great change in the opinion of the society, not in any religious tenet, but in its view of certain social practices. Though neither George Fox nor the early Friends established any particular costume, as is commonly imagined they did, but merely adhered to the fashion of their own day, discarding all sorts of finery from it, the practice of the society in adhering to the fashion of their day, in spite of the perpetual changes of fashion, had, in fact, established a costume of Quakerism in marked contrast to the costume of the present age. The world had gone on changing; the Quakers had endeavoured to stand still. They had not, indeed, been able to stand perfectly still. Spite of themselves, changes and modifications of dress, both in men and women, had gradually stolen in; so that the costume of modern Friends was neither that of the age of Fox and Penn nor of any other age. In the main, it was singularly formal, stiff, bald, and ungraceful.

But in other particulars the first Friends had introduced remarkable changes into their language and customs, in direct opposition to the spirit and practice of the world. As it was the invidious practice of their time to address rich men as "you," and poor men as "thou," they condemned the custom as unchristian and corrupt, and determined to address every one alike in the singular number, as most consonant with the rules of grammar. As the days of the week and the months were for the most part named in honour of heathen gods and heroes, they discarded these names, and designated them only by numerals, as First Day, Second Day; First Month, Second Month, &c. All these reforms, which appear to us now trivial and far-fetched, were, however, founded in the practice of the early Quakers in that noble resistance to everything corrupt, adulatory, invidious, and unjust, which ran through their whole spirit and system.

But the Friends of late saw that the odious practice of saying "thou" to a poor man, and "you" to a rich, had ceased; that the practice of saying "Mr," "Mrs," "Sir," or "Madam" in address was no longer a piece of flattery, but of simple courtesy, and of much greater truth than calling any one friend who really was no friend at all. To this conference meeting in November 1858 was referred the question, whether there ought not to be a modification of the fourth of a set of queries which had to be answered once a quarter from every district of the society, the latter part of which query demanded whether Friends were faithful in maintaining "plainness of speech, behaviour, and apparel." It was contended that these words had, through time, acquired a false value; that they must bind Friends to a particular costume which the first Friends never intended, and to a language which only testified against an obsolete custom; that the words in the minds of the first Friends applied only to the practice of simplicity in dress, address, and language, but that they had now obtained another meaning, and went to perpetuate forms which were only sectarian, were not necessarily Christian, and had therefore better be omitted; and the conference also adopted this conclusion. The fiat of the conference has yet to receive the sanction of the yearly meeting; but as it is not likely to stultify its own reference, Friends feel themselves practically released from everything sectarian in regard to speech, behaviour, and apparel; to abandon all that in the world's eye stood as the visible form of Quakerism, and to adopt every one for himself what he deems consonant with the great principles of simplicity and Christian propriety.

Many of the public journals have professed to see in this great change the dissolution of the principles of Quakerism itself; but this arises from an ignorance of what Quakerism really is. Quakerism consists of a body of great Christian principles, which are already detailed in this article. The outward forms, as they became sectarian, only disguised and hid from public view these great principles. Quakerism does not depend, has never depended in the slightest degree, on the forms of caps or coats, or on any forms of speech, but on the high and independent assertion of the great doctrines of Christianity. As is the nature of all artificial props, "the peculiarities" of Quakerism have only tended to cause the Friends to lean on them instead of on their great and real principles, and to deceive the world by an idea of Quakerism as a religion of forms and oddities, whereas it is one of the noblest truths and the most solemn protests against whatever is unjust, oppressive, hollow, degrading, or demoralizing in the principles and practices of the world; and we may feel assured that all these false props being thrown down, and Quakerism left to depend for distinction only on its genuine and undisguised principles, will make those principles more prominent than ever.

For a full account of the schism amongst the American Friends, we must refer to *The Friend*, and *The Herald of Truth*, journals published by the opposite parties; *The Beacon*, and *Christian Enquirer;* all published in America.

In *The Christian Reformer*, a London journal, a narrative may also be found, vols. xiii. xiv. xv. xvii. and xviii., old series. The English discussion has occasioned a host of pamphlets, but the chief facts regarding it are contained in *The Beacon*, by Isaac Crewdson; *Truth Vindicated; The Crisis of the Quaker Controversy; Quakerism Examined*, by John Wilkinson; *An Examination of the Principles and Practices of the Quakers*, by Elisha Bates; Luke Howard's *Yorkshireman;* Reports of the proceedings in the Yearly Meetings of 1835 and 1836, in the *Christian Advocate* and *Patriot* newspapers; and defensive pamphlets by S. Tuke, Dr Hancocke, and others.

The history and doctrines of the early Friends will be found in George Fox's *Journal;* Barclay's *Apology for the True Christian Divinity; The Histories of the Society*, by Sewel and Gough; *The History of the Sufferings of the Quakers*, by Besse; *The History of the Friends in Ireland*, by Rutty; Ellwood's *Life*, written by himself; and the works of William Penn, Richard Claridge, and others. (W. H—T.)

QUANG-SI, or KUANG-SI, an inland province of China, lying between N. Lat. 22. and 26., E. Long. 105. and 112. 30.; bounded on the W. by the province of Yunnan, N. by those of Kwi-choo and Hoonan, E. by that of Quantong, and S. by Quan-tong and the country of Tonquin; area, 78,377 square miles. A great part of the surface is mountainous and densely wooded; cultivation is carried on only along the banks of the Choo-kiang, which traverses the province from W. to E. Wheat, rice, wild cinnamon, &c., grow here; and among the minerals of the province are gold, silver, lead, and cinnabar. The capital is Kwelin-foo, a fortified town on the Hei-kiang, but Wu-chau-foo is the principal commercial town in the province. Pop. (1812) 7,313,895; (1843) 7,500,000.

QUANG-TONG, or KUANG-TUNG, a province of China, lying between N. Lat. 20. and 25. 30., E. Long. 108. and 117., bounded on the N.W., N., and N.E. by the provinces of Quang-si, Hoonan, Kiang-si, and Fokien; S.E. and S. by the China Sea and Gulf of Tonquin; area 70,018 square miles. The surface is of various characters in different parts, being mountainous towards the N. of the province; and the soil is in general fertile. The Choo-kiang, or Canton River, and other streams of smaller size, water the country. Gold, quicksilver, and marble are among the mineral productions. Rice, sugar, indigo, tobacco, cotton, and silk, are also raised; and the forests produce oak, rosewood, and other kinds of timber. Many manufactures are carried on here, and the trade is extensive. The capital of the province is Canton. Pop. (1812) 19,174,030; (1843) 20,000,000.

QUANTITY, in prosody, is the distribution of long, short, and doubtful syllables, and constitutes what is called *number*.

QUARANTINE (It. *quaranto*, forty), is a trial which ships must undergo when suspected of pestilential infection. It may be ordered by her Majesty, with advice of the Privy Council, at such times and under such regulations as she judges proper. Ships ordered on quarantine must repair to the place appointed, and continue there during the time prescribed; and they must carry a yellow flag at the main, and have no intercourse with the shore except for necessary provisions, which are conveyed with every possible precaution. When the time is expired, and the goods have been opened and exposed to the air as directed, if there be no appearance of infection, they are admitted to port. This check to infection was first used by the Venetians. (See PLAGUE; also M'Culloch's *Comm. Dictionary.*)

QUARLES, FRANCIS, a poet and miscellaneous writer of some note, was born in the spring of 1592 at Stewards, in Romford Town Ward, in the county of Essex. He received his early education at a country school, where he is said to have surpassed all his equals." He subsequently entered Christ's College, Cambridge, and was a resident member of that university in 1608. Passing from the university, he entered Lincoln's Inn, where he spent some time in the study of law, and was afterwards promoted to the office of cup-bearer to the Queen of Bohemia. In the spring of 1621 he seems to have left her majesty's service, for we find him in Dublin at that period, from which place he dates his *History of Argalus and Parthenia.* This was not his first effort, however. He had before written *The Feast of Worms, or the History of Jonah*, a somewhat singular poem, in which strength, coarseness, and breadth of colouring are all equally visible. On visiting Ireland, he became secretary to the learned Usher, recently elevated to the see of Meath. Quarles wrote, about this period, his *Quintessence of Meditation* and his *History of Queen Esther*. His next work consisted of a paraphrase upon Job, interspersed with original meditations. In 1625 Quarles lost one of his most esteemed friends by the plague, in Dr Aylmer, archdeacon of London, and son of Bishop Aylmer. The poet wrote an *Alphabet of Elegies* in honour of his memory, in which there are some of the most precious tributes of sincere affection to be found in our language. He printed during the same year *Zion's Elegies*, a paraphrase upon the songs of mourning "wept by Jeremie the prophet." In 1631 was published his *History of Sampson*, and in 1635 the first issue of his *Emblems*, suggested by the *Pia Desideria* of Herman Hugo. He occasionally strikes out in these *Emblems*, as indeed in all his poetry, images of very great sublimity. In one of these he represents the sword of justice swinging through the universe with ever-increasing power. His next eccentricity was his *Hieroglyphics*, "an Egyptian dish, drest in the English fashion." Prefixed to one of these he represents a lighted taper, with the winds of eternity fanning the flame.

On Quarles' return to England, which must have been before February 4, 1639, he was appointed "Chronologer" to the city of London, with a salary of L.33, 6s. 8d. The *Enchiridion*, a collection of brief essays and aphorisms, appeared in 1641; a piece, according to Mr Headly, which had it "been written at Athens or Rome, its author would have been classed with the wise men of his country." But the vigour, eloquence, and piety of the sentiments do not atone for the frequent use of antithesis, often of the most perverse and self-willed description. They possess a novelty at first, which leads the reader forward, but he will infallibly break down long before reaching the end. The calamities which befell his "king and country" involved Quarles, whose love to both, says his widow, caused him many "prayers and tears." His *Thoughts upon Peace and War*, full of mild wisdom as they were, did not prevent him from being plundered of his "books and some rare manuscripts." A petition "full of unjust aspersions," says his widow, was preferred against him, from which he did not recover. He died on the 8th of September 1644.

After his death were published *Solomon's Recantation; A Paraphrase on Ecclesiastes;* the *Virgin Widow*, a comedy, "an innocent production;" and the *Shepherd's Oracles*. Quarles's *School of the Heart* and *Hieroglyphics* were published in London in 1858, and his *Emblems* in 1859, with illustrations. A copy of the *Enchiridion* of Francis Quarles has recently been published by Russell Smith in the "Library of Old Authors." The most complete biography of the poet is that by Robert Aris Willmott, in his *Lives of Sacred Poets*, London, 1835.

Of Quarles' very numerous family, John is alone remembered, whose compositions seem to have been very numerous. He was by some "esteemed a good poet," though falling considerably short of his father, both in power and originality. He was carried off by the plague in 1665.

QUARRY, an excavation, from which are extracted marble, freestone, slate, limestone, or other building materials.

Quarry, amongst hunters, is sometimes used for a part of the entrails of the beast taken, which is given by way of reward to the hounds.

Quarry, in falconry, is the game which the hawk is in pursuit of, or has killed.

QUART, a measure of capacity, being the fourth part of some other measure. The English quart is the fourth part of the gallon, and contains two pints.

QUARTATION, in metallurgy, is an operation by which the quantity of one metal is made equal to a fourth part of the quantity of another. Thus when gold alloyed with silver is to be parted, we are obliged to facilitate the action of the aquafortis by reducing the quantity of the former of these metals to one-fourth part of the whole mass, which is done by increasing the quantity of the silver as far as necessary.

QUARTER, the fourth part of anything, the fractional expression for which is $\frac{1}{4}$.

Quarter is generally used to signify the fourth part of an hundredweight avoirdupois, or twenty-eight pounds. Quarter, used as the name of a dry measure, is the fourth part of a ton in weight, or eight bushels.

Quarters of a horse is employed in various senses. Thus the shoulders and fore-legs are called the *fore-quarters*, and the hips and hinder-legs the *hind-quarters*. The quarters of a horse's foot are the sides of the coffin, comprehended between the toe and the heel; the *inner* quarters are those opposite to one another, facing from one foot to the other, and these are always weaker than the *outside* quarters, which lie on the external sides of the coffin. *False-quarters* are a cleft in the horn of a horse's hoof, extending from the coronet to the shoe. A horse is said to be a *quarter-cast* when, for any disorder in the coffin, we are obliged to cut one of the quarters of the hoof.

Quarter, in astronomy, the fourth part of the moon's period. Thus from the new moon to the quadrature is the first quarter; from this to full moon, the second quarter; and so on.

Quarter. See Heraldry.

Quarter of a Ship, that part of a ship's side which lies towards the stern, or which is comprehended between the aftmost end of the main chains and the sides of the stern, where it is terminated by the quarter-pieces.

Quarter-Master, an officer whose principal business it is to look after the quarters of the soldiers, their clothing, bread, ammunition, firing, and the like.

Quarter-Master-General is an important officer in the army, whose duty it is to mark out to the quarter-masters the marches and encampments of the soldiers. (See Army.)

QUARTERING. See Heraldry.

QUARTETTO, *Quartet*, in music, a composition for four voices, or four instruments, in which the parts are all *obbligati*; that is, in which no one of the parts can be omitted without injuring the proper effect of the composition. To understand the structure of instrumental quartettos of this kind, those of Haydn, Mozart, Beethoven, Spohr, Onslow, and a very few others, must be examined. Vocal quartettos are generally accompanied by instruments, to sustain the voices. A mere interchange of melody between one part and another, where the parts alternately become principal and subordinate, without any interweaving of them by means of imitations, double counterpoint, &c., does not constitute a regular quartetto. Neither is a regular quartetto found in a composition that consists of one principal part, accompanied from beginning to end by three other parts, which are merely harmonic supports to the principal part. (See Music, and Principal.) (G. F. G.)

QUATRE-BRAS, a village of Belgium, in the province of South Brabant, 26 miles S.S.E. of Brussels. It is only notable on account of the indecisive battle that was fought here, June 16, 1815, two days before that of Waterloo. The British troops then occupied this position, while the Prussians under Blucher were at the village of St Arnaud and Ligny. Napoleon attacked the latter in person; and after meeting with a desperate resistance, forced them to retire to Wavre. Meanwhile Ney, with 40,000 men, advanced against the British, but they stood firm, and thus foiled the attempt of Ney to turn Blucher's right, and place himself between the Prussians and the British. The loss of the British at Quatre-Bras was 350 killed and 2380 wounded; that of the French above 4000.

QUATREMÈRE-DE-QUINCY, Antoine Chrysostome, a distinguished French archæologist, was born at Paris in 1758. He was just beginning to be known as a writer on art, when he became involved in the political broils of the French revolution. Entering the Legislative Assembly in 1791, he took his stand for constitutional monarchy. His unswerving adherence to that cause brought him into trouble and danger at several of the momentous stages of the struggle. During the Reign of Terror he lay for thirteen months in prison. After the insurrection of the 13th Vendémiaire he was sentenced to death, and was obliged to skulk in concealment for nearly a year. In 1797 also, the year in which he sat in the council of the Five Hundred, he would have been banished to Cayenne, had he not consulted his safety by a temporary absence from the capital. The rest of Quatremère-de-Quincy's long life was spent in peaceful activity. There were several offices in connection with learning to which he was called at different times. In 1814 Louis XVIII. made him censor-royal, and intendant of arts and public monuments. In 1815 he was named member of the Council of Public Instruction. In the following year the Institute elected him a member, and the Academy of the Fine Arts appointed him their perpetual honorary secretary. Nor were his literary faculties meanwhile unemployed. He wrote numerous works on the history and theory of art. He composed funeral orations on many of his fellow-academicians. It was not until a few years before his death, in 1849, that his pen was laid aside. The following are some of Quatremère-de-Quincy's principal works:—

Le Jupiter Olympien, 1814; *Lettres Addressées à M. Canova sur les Marbres d'Elgin*, 8vo, Rome, 1818; *De la Nature, du But, et des Moyens de l'Imitation dans les Beaux Arts*, 8vo, 1823; *Histoire de la Vie et des Ouvrages de Raphael*, 1824; *Monumens et Ouvrages d'Art Antiques restitués*, 4to, Paris, 1826–1829; and *Essai sur l'Idéal*, 1837.

QUATUORVIR, formerly written IIII. Vir, a Roman magistrate, who had three colleagues joined with him in the same administration, and had the care of conducting and settling the colonies sent into the provinces. There were also quatuorviri appointed to inspect and take care of repairs.

QUAVER, in music, a measure of time equal to half a crotchet, or an eighth part of a semibreve.

QUEBEC, a town of East Canada, the chief seaport and strongest military position in British North America, on a rocky promontory at the confluence of the rivers St Lawrence and St Charles, 170 miles below Montreal, and 556 N. by E. of New York. The country in which it stands is much admired for the boldness and sublimity of its scenery; the left bank of the St Lawrence is lined for some distance above the town with an elevated strip of table land, on the extremity of which the town is built. The citadel, which occupies the highest point, has an elevation of 350 feet above the river,—the declivity being steep on the S.E. side, but more gradual towards the N. and W., where the ground slopes towards the St Charles. It is on the latter side that Quebec is built,—the upper town on an elevated slope, about 100 feet below the citadel, and terminating in steep cliffs 200 feet high; while the lower town occupies the narrow strip of land between these cliffs and the river. To the west there are two large suburbs,—that of St Roche occupying the lower plain, which here expands to a greater width; and that of St John, on the same level as the upper town. To the S.W. of the latter are the plains of Abraham. The citadel, which covers an area of 40 acres, is considered almost impregnable, being defended for the most of its circuit by steep precipices; and in other places by strong and skilfully-constructed fortifications, consisting of a moat, covered way, and glacis. There are in the citadel barracks, magazines, and a large armoury. The upper town is encircled by a wall, which is mounted with heavy ordnance, and entered by five gates. The approach to the upper from the lower town is commanded by well-placed cannons in the citadel. On the plains of Abraham, outside of the suburb of St John, there are four Martello towers, extending across the ridge, which defend the city from attack in this direction. The houses in Quebec are in general two or three storeys in height, built of stone or brick, and roofed with shingles or tin plates, so as to present a singular and antique appearance. The lower town, owing to the confined and uneven ground on which it is built, is very irregular, with short, narrow, and crooked streets; but in the upper town, and especially in the suburbs, there is more regularity,—the streets are broad, straight, well paved, and clean. There are many public buildings, some of which are large and handsome. The Parliament buildings, formerly the episcopal palace, is a large edifice in the Ionic style, surmounted by a dome. The Roman Catholic cathedral of Notre Dame is an irregular building of great size, with a tower and spire, and it contains many fine old paintings. There is also a Protestant cathedral, a plain edifice in the Roman style. The Roman Catholic Church has six other places of worship; the Church of England, five; the Established and the Free Church of Scotland, the French Protestants, the Congregationalists, Wesleyans, and Baptists, one each. The public buildings in general are more remarkable for their substantial character than for any great elegance. Among the ornaments of the town, the most interesting are those which commemorate the celebrated victory by which Quebec came into the possession of the British. A monument to General Wolfe, consisting of a column 40 feet high, stands on the plains of Abraham; a smaller pillar marks the place where he fell; and inside the town there is an obelisk, 65 feet in height, in honour of Wolfe and his adversary Montcalm, who both died in the battle, and lie buried on the field. Laval university derives its name from the first Roman Catholic bishop of Canada, who founded in 1663 an institution, called the Quebec Seminary, for the education of priests. When the British gained possession of Canada this was made a general college; and having risen considerably in importance, was in 1852 erected by royal charter into a university. The buildings are only partially finished, and none but the faculties of law and medicine are yet in operation. The university has 12 professors, 36 students, and a library of 3200 volumes. The collegiate department comprises the institution as it was before being made a university, and includes the grand seminary for the study of theology, and the minor seminary for literature and philosophy. Quebec has also a normal school, and several literary and scientific institutions. The benevolent institutions include the Hotel Dieu, a nunnery and hospital; a lunatic asylum; military, marine, general, and orphan hospitals, &c. Though not very remarkable as a manufacturing town, various branches of industry are carried on at Quebec: soap, candles, tobacco, beer, and brandy are made here; but ship-building is the employment that occupies the greater number of operatives in the town. The number of vessels annually built and equipped is from 30 to 40, and the tonnage 1000 or 2000. The harbour of Quebec is very good. It is protected towards the N.E. by the island of Orleans, on either side of which there is an approach. Vessels of the largest size can lie in the middle of the stream, where there is excellent anchorage; and smaller ones come alongside the wharves which line the water's edge. The water here is fresh, but yet the tide has 18 feet at springs. The chief article of export from Quebec is timber, which is floated down the river from the basin of the Ottawa and the north shore of Lake Ontario, and is laid up in coves extending along the river for 6 miles above the town. From these coves the timber is floated out to the ships in the harbour. Quebec is the principal emporium of the export trade between Canada and Great Britain; while the imports, on the other hand, are generally conveyed directly up to Montreal, which in that respect is much superior. The number, tonnage, and crews of the vessels entered and cleared at Quebec for several years is as follows:—

Year.	Entered.			Cleared.		
	No.	Tons.	Crews.	No.	Tons.	Crews.
1845......	1489	576,541	20,912	1499	484,540	...
1848......	1188	452,436	16,423	1194	457,430	...
1851......	1305	533,821	17,753	1394	586,093	...
1854......	1416	618,926	20,301	1558	693,588	22,166
1856......	990	462,083	14,783	1068	495,867	15,651

The quantity of timber conveyed to the town and exported in 1854, was as follows:—

	Supply.	*Export.*
	Feet.	Feet.
Oak	2,176,071	1,335,920
Elm	1,927,865	1,463,600
Ash	221,446	106,160
Birch	45,052	51,160
Temarac	2,649,759	78,560
White pine..........................	19,648,006	19,612,320
Red pine	3,756,848	2,699,080
Total	30,425,047	25,346,800

The total value of exports in 1856 was L.2,048,299, of imports L.071,598, and of import duty received L.92,477.

Quebec has been several times devastated by terrible fires, the last of which occurred in 1845; but it is now guarded against this danger by a copious supply of water from Lake St Charles, which can be thrown by its own pressure over the highest edifices. The city is governed by a mayor and twenty-four councillors, and returns three members to the legislative assembly. It was founded by the French in 1608, and fortified in 1690. It remained in their hands till 1759, when, in consequence of the victory of Wolfe, it was surrendered to the British, and finally confirmed to them by the treaty of Paris in 1763. It was attacked by the American republicans in 1775, but the siege was raised in the following year. Since then its capture has not been again attempted. Pop. (1851) of the city, 42,052; of the county, 61,566; (1857) of the city, about 60,000, chiefly of French origin.

QUEDAH, or KEDAH, a native state in the Malay peninsula, dependent on the empire of Siam, lying between N. Lat. 5. and 7., E. Long. (of the capital) 100. 30, bounded on the N. by Siam proper; E. by the dependent states of Patani, Kalantan, and Tringanu; S. by the independent state of Perak; and W. by the British province

Wellesley and the ocean. It is about 140 miles in length by 50 in average breadth. The coast is skirted with many small islands, and is difficult of access on account of the shallowness of the water. The country consists for the most part of a plain, but slightly elevated above the level of the sea, and traversed by a chain of hills from N. to S. about 20 miles inland. The soil is fertile, though little cultivated, and covered in many places with vast forests. Rice, cocoa-nuts, plantains, and betel-nuts, are among the vegetable productions of Quedah; and gold, iron, and tin are its chief mineral riches. The subjection of Quedah to Siam is little more than nominal. The rajah of Quedah receives a pension from the British government in return for the cession of Prince of Wales Island and Province Wellesley. The capital of the state is Quedah, at the mouth of the river of the same name; and an active trade is carried on with Prince of Wales Island in the produce of the country, especially in tin. Pop. of the state, 65,000; of the town, 8000.

QUEDLINBURG, a town of Prussia, in the province of Saxony and circle of Magdeburg, on the Bode, 35 miles S.W. of Magdeburg. It is well built, and encircled by walls flanked with towers, and entered by ten gates. Its most conspicuous edifice is the castle, which rises on a sandstone rock above the rest of the town. It was the residence of the abbesses of Quedlinburg, who, as princesses of the empire, had a vote in the Diet, and a Seat in the bench of bishops. The church, which was partly built in the eleventh, and partly in the fourteenth century, contains the graves of the Emperor Henry I. and his wife Matilda; of Aurora Maria, Countess of Konigsmark, and mother of Marshal Saxe; and of several abbesses of Quedlinburg. The castle is now used as a seminary for young ladies of rank. The town-hall of Quedlinburg contains numerous specimens of ancient armour, plate, and portraits, as well as a manuscript of the ancient code of law called the *Sachsenspiegel.* Here is also shown a large and strong chest in which Albert Count of Reinstein was confined for 20 months by the citizens of Quedlinburg. The town contains a gymnasium and several hospitals, including one for orphans and another for the deaf-and-dumb. Woollen cloth, beet-root sugar, and brandy are manufactured here; and a trade in corn is carried on. The poet Klopstock was born here in 1724. Pop. (1852) 14,258.

QUEEN (Saxon *cwaen*), was employed to denote *femina, mulier, conjux*, as well as the most noted of women and wives, to whom now it is only appropriated. The use of *queen* as a sovereign princess who reigns in her own right, and possesses all the powers which are the prerogative of a male who is endowed with kingly authority, is an application of the word which was not originally contemplated. The king's consort has been regarded in all countries as a person of eminent dignity, and who has possessed privileges granted to no other woman, whether married or single. A queen-consort, in England, is regarded in all legal proceedings as a single and not as a married woman. She is competent to purchase and convey lands, to grant leases, and to do other acts of ownership, without the king's intervention. She may have a separate property in goods, and may dispose of them by will. She pays no toll, and is free from amercement by any court. She is, however, to all intents the king's subject, and is generally upon the same footing with other subjects. Her majesty has separate courts and officers distinct from the king's, not only in matters of ceremony, but by ancient usage of law; and her attorney and solicitor-general are entitled to a place within the bar in the king's courts. Her personal expenses are defrayed from the king's privy purse. A queen-dowager enjoys most of the privileges which belonged to her as Queen-Consort.

A queen regnant differs in no respect from a king as to the political rights vested in the dignity.

The Hungarians have an aversion to the name of *queen*, and when a female ascends the throne, she reigns with the title of *king*. (See MARIA THERESA.)

QUEEN ANNE'S BOUNTY, the name applied to a perpetual fund of first-fruits and tenths which was granted and confirmed by Queen Anne (statute 2 and 3 Anne, c. 11) in 1704 for the augmentation of the livings of the poorer clergy. These first-fruits and tenths formed originally part of the papal exactions from the clergy. The former consist of the first whole year's profit of all spiritual preferments, and the latter of one-tenth of their annual profits. The poorer livings are now exempted from the tax. On the abolition of the papal authority, the income thus derived was annexed to the revenues of the crown (26 Henry VIII.), and so continued till the reign of Queen Anne. The governors consist of the archbishops and bishops, some of the principal officers of the government, and the chief legal authorities. They hold four courts yearly. About 4700 livings are charged with the payment of first-fruits, and about 5000 charged with the payment of yearly tenths. The average income from these sources is L.14,000 yearly. To the end of the year 1852, the capital appropriated to small livings, including L.1,000,000 from parliamentary grants, and L.1,530,400 from benefactions, was L.5,027,200. The governors have received from Parliament, to whom they present an annual account, between 1809 and 1820, the sum of L.1,100,000, being the product of eleven sums distributed during that time for augmenting the incomes of the clergy. By 1 and 2 Vict., c. 20, the offices are consolidated in the treasurer of the Queen Anne's Bounty. The treasurer and secretary, offices now held jointly with a salary of L.1000 a year, are appointed by the Queen during her pleasure by patent under the great seal. (See *The Official Handbook.*)

QUEEN CHARLOTTE ISLANDS, a group of islands in Australasia, lying between S. Lat. 10. and 12., E. Long. 165. and 168., consisting of five or six islands of considerable size, and a great number of smaller ones. The largest is Santa Cruz, or, in the native language, *Nitandi*, about 20 miles in length by half a mile in breadth. They are all of volcanic origin; and in one, called Volcano, this agency is not yet extinct. The larger islands, and some of the others, are lofty; and they are all well wooded, producing the cocoa-nut tree, the bread-fruit tree, and other vegetables similar to those of the Friendly Islands. The inhabitants are numerous in proportion to the area, and they belong to the race of Australian Negroes. Queen Charlotte Islands were discovered by Mandana in 1595, and it is at Mallicollo, or Recherche, one of this group, that the unfortunate La Pèrouse is believed to have been lost with his crew.

QUEEN'S COLLEGES. (See UNIVERSITIES.)

QUEEN'S COUNTY, an inland county in the province of Leinster, in Ireland, bounded on the north by the King's County, east by Kildare and Carlow, south by Carlow and Kilkenny, and west by Tipperary and the King's County. It extends over a surface of 664 square miles, or 424,854 acres, of which 342,422 are arable, 69,289 uncultivated, 11,630 in plantations, 1117 in towns, and 396 under water. Of the uncultivated ground about 18,000 acres, consisting partly of pasture land on the eastern declivity of the Slieve-Bloom Mountains, but chiefly of bog and boggy pasture, are capable of being drained and cultivated advantageously; 26,000 acres may be improved by draining for pasture; and the remaining 25,000 acres are unimproveable.

No notice of the inhabitants of this part of Ireland is to be found in Ptolemy's account of the island; but Whitaker supposes it to have been peopled, together with all the other interior parts, by the Scots. It was afterwards known by the names of *Ossory* and *Leix;* the former consisting of the north-western districts, the latter of the remainder of the county, and the Barrow constituting the boundary between them. Ossory, of which the Macgillypatricks or Fitzpatricks were the toparchs, ranked as a subordinate kingdom at the landing of the English, and for some time afterwards. Leix was made a county palatine, which fell into the possession of Roger Mortimer through the female line, and afterwards was seized on by the O'Mores, who retained possession of it, and proved persevering and troublesome enemies to the English government, until the reign of Philip and Mary, when the territory was made shire-ground, under the name of the Queen's County, in honour of the sovereign; and the place chosen for the county town was named Maryborough, for the same reason. This county, when brought under British law, was gradually peopled by English settlers. During the subsequent reigns several of these families became extinct in the male line; many were expelled or extinguished by the confiscations arising out of the civil wars in 1641 and 1689; whilst the descendants of others, the principal of whom are the Veseys, Cootes, Parnells, Dawsons, and Burrowes, still retain the whole or some portion of their ancestral possessions. The Queen's County is now divided into the baronies of Ballyadams, Clandonagh, Clarmallagh, Cullinagh, Maryborough East, Maryborough West, Partnahinch, Slievemarigue, Stradbally, Tinnehinch, and Upperwoods. These are subdivided into thirty-eight parishes, and six parts of parishes, the remaining parts of which are in the adjoining counties. According to the ecclesiastical arrangements of the country, the county contains fifty-three parishes, of which thirty-five are in the dioceses of Leighlin and Kildare, and fifteen in Ossary, the remainder forming part of the dioceses of Killaloe and Dublin.

The general face of the country is level, but it rises into heights of considerable elevation in the Slieve-Bloom Mountains, which, taking a direction nearly north and south along the western verge of the county, rise to a considerable height, their most elevated point being 1689 feet above the level of the sea, and with an acclivity so abrupt that the only practicable road across them is through the pass of Glandine. In the southern extremity the Slievemarigue Hills, of considerably inferior elevation, separate the county from that of Kilkenny. The monotony of a generally level surface is somewhat relieved by a range of low hills, which traverse it in a direction from north to south, the most remarkable of which are the Rock of Dunamaise and the Dun of Clopoke; as also by eskars, a singular species of low hills, or rather slight elevations of the surface, formed of rounded pebbles, apparently forced together by the operation of contending currents of water. The most remarkable of these is the Ridge of Maryborough, which, entering from the King's County, proceeds for a considerable distance by Maryborough, and, after having been deranged and broken, resumes again the form of a continuous ridge, branching out in the southern part of the county in two divisions. The Slieve-Bloom Mountains give rise to some of the great rivers of Ireland. The Barrow rises at their northern extremity, and, after passing through the north of the county, forms its north-eastern boundary; then, turning southwards, it forms its boundary to the east, separating it from Kildare and Carlow, and falls into the Suir some miles below New Ross, forming with that river the estuary called Waterford Harbour. The source of the Nore is southward of that of the Barrow, in the same mountains. It passes through the south-western part of the county by Abbeyleix and Ballynakill, enters the county of Kilkenny near Ballyragget, and, after flowing by the city of Kilkenny, joins the Barrow about two miles above New Ross. The portion of the Barrow between its junction with the Nore and Suir is generally called the Ross River. The Suir, which also rises in the Slieve-Bloom Mountains at their southern extremity, does not belong to this county. These three rivers, the Barrow, Nore, and Suir, are, next to the Shannon, the chief means of transmitting the waters of the great central limestone district of Ireland to the sea. The smaller rivers are the Ownas, Trihogue, and Blackwater, tributaries of the Barrow; and the Tonnet, Dolore, Old Forge River, Cloncoose, Cromoge, Corbally, Trumry, Colt, and Erkin, tributaries of the Nore. Under the name of the Barrow Navigation, the River Barrow is navigable for barges from Athy, where it joins the Grand Canal to the Scars below St Mullins, a distance of 43 miles; from thence there is an open navigation for large craft, passing by New Ross and Waterford to the sea. The Nore is not navigable until after it has quitted the county. There is no lake except Lough Annagh on its northern boundary, which partly belongs to the King's County, and does not exceed one mile in length.

The population of this county in 1812 was 113,857; 1821, 134,275; 1831, 145,851; 1841, 153,930; 1851, 111,623. The return of 1841 gives an average of 232 inhabitants to each square mile, that of 1851 exhibits only 168, being a reduction of 64; the decrease in the population of all Ireland for the same period having been 49 persons to each square mile.

The county returned eight members to the Irish Parliament; two for the county at large, and two each for the boroughs of Portarlington, Maryborough, and Ballynakill. This number was reduced to three by the Act of Union, by which the boroughs were disfranchised, with the exception of the first-named. The number of registered electors for the county, according to the latest return, was 2993; that of the borough of Portarlington, 96. The local government consists of a lieutenant, eighteen deputy-lieutenants,—all appointed by the crown during pleasure; and county magistrates, appointed by the lord chancellor. The constabulary force consists of a county inspector, eight sub-inspectors, eight head constables, fifty-one constables, and one hundred and eighty-five sub-constables; in all, 253.

The state of education, according to the parliamentary returns in 1821 and 1824–26, was as follows:—

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821	4825	1998	...	6,823
1824–6	6624	4908	231	11,763

Of the numbers stated in the latter of these returns, 2074 were Episcopalian Protestants, 104 Protestant dissenters, and 9426 Roman Catholics; the religious persuasion of the remaining 305 not having been ascertained. The number of schools, and of pupils attending them during the week ended 12th April 1851, was ascertained to be as follows:—

Description of Schools.	No. of Schools.	No. of Children.		
		Males.	Females.	Total.
National	58	1658	1746	3404
Church Education	24	461	376	837
Endowed	2	33	20	53
Boarding	11	218	151	369
Private	35	356	265	621
Parochial	17	314	268	582
Free	7	243	123	366
Mission	1	22	...	22
Workhouse	3	795	436	1231
Gaol	1	155	61	216
Total	159	4255	3446	7701

At the same period it was found that 37 per cent. of the population could neither read nor write; a proportion of ignorance below all the counties of Connaught and Munster, and several in the other provinces.

The level part of the county forms the southern portion of the great limestone field which traverses Ireland across its centre. The peculiar flatness of the interior appears to have caused those accumulations of alluvial matter, composed of clay and limestone gravel, which, in the form of low but steep ridges of hills, occur so frequently throughout the midland districts, and are known by the name of *eskars*. Some very striking specimens of this formation in the county have already been noticed. That the surface of the country was exposed to the action of rapid currents of water, is evidenced by the deep parallel indentations or furrows frequently observable on the surface of rocks from which the alluvial soil has been removed. It is also probable that the gravel hills were rapidly deposited from water in violent action; an inference which is confirmed by the fact, that they mostly consist of large masses of rock partially rounded, intermixed with small gravel, and even with clay and sand. The old red sandstone shows itself in the Slieve-Bloom Mountains, which are almost wholly of that formation. The south-eastern extremity forms a small part of the Leinster coal-field, the mineral in it being, like that of Kilkenny, which adjoins it, of the carbonaceous or stone-coal formation, the slaty glantz-coal of Werner, burning dully with little flame, emitting an offensive and unwholesome vapour, and therefore disagreeable for domestic use, but excellent for malting or for the forge. Iron was raised here, and two hundred years ago was an article of export, through the port of Waterford, to London. The works were carried on as long as the forests afforded materials for fuel. Potters' earth is also raised, and applied, in the neighbourhood of Mountmellick, to the manufacture of the coarser kinds of earthenwares.

The soil varies greatly in different parts, but is in general fertile. Where it rests on the limestone substratum, it consists mostly of a stiff clay loam, well adapted for the growth of wheat; in other parts it is light and sandy, and produces good crops of oats and barley. The mountain district is wet and boggy, even in the higher parts, the clayey subsoil not admitting free passage for the water, which therefore accumulates on the surface: it is also much encumbered with rock. The low hills that traverse the middle of the county from north to south are capable of culture to their summits, and, where not deemed suitable for the plough, afford rich pasturage for sheep. The tracts on the sides of the rivers, being annually flooded by the overflowings of the stream during winter, form rich meadowland. Bogs are frequent in most parts, supplying ample fuel for domestic purposes. The county was once so thickly wooded as to be almost impenetrable for the passage of large bodies of men; and thence, as well as from the bogs, which, from a different cause, were also difficult to be crossed by those not well acquainted with their peculiarities, the natives were enabled to hold out long against the attempts of the English settlers. But the old woods have long since been cleared away, the only proof of their former existence being discoverable in the numerous remains of timber-trees lying in the bottom of Lough Annagh. A new growth, however, the offspring not of the unaided efforts of nature, but of the hand of modern improvement, has in a great measure restored one of its most beautiful and useful features. Large plantations, chiefly around the demesnes of the gentry, vary the prospect, and tend much to relieve the monotony of the level surface. Most parts present the mansions and seats of resident proprietors; comfortable farm-houses are numerous, and much attention has been paid by many landlords to excite amongst their tenantry a laudable emulation in the neatness of their cottages, and in the judicious cultivation of their little farms. The coal-district, and some few other localities, must, however, form exceptions to this general description,—the appearance of the peasantry, both in their persons and dwellings, exhibiting too frequent instances of the destitution consequent on extreme poverty or confirmed habits of improvidence. With the exception of the lands held by wealthy proprietors in their own hands, and those in the mountainous parts, where grazing is the chief object, the farms are not large, seldom more than from ten to fifteen acres. Wheat is extensively grown, its culture being attended to even on those soils which, during the more confined state of agricultural knowledge, were thought to be unfit for it. The lighter soils answer well for barley and oats. Potatoes are everywhere raised, both for family use and for feeding cattle,—forming also an essential part of the improved rotation system, which is generally practised. Green crops, particularly turnips, are not unusual; and the value of every kind of clover seems to be duly appreciated. The description of crops, and the extent of land under cultivation of late years, have been as follows:—

	1853.	1855.	1858.
Wheat	18,873	21,500	22,218
Oats	35,397	32,587	27,575
Barley, bere, rye, beans and pease	11.219	9,683	10,405
Potatoes	19,617	20,875	23,758
Turnips	14,606	14,231	14,225
Other green crops	2,260	1,958	2,605
Flax	14	7	29
Meadow and clover	49,665	51,931	55,734
Total	151,651	152,772	156,549

Much attention is given to the introduction of implements and machines of the best description,—the clumsy and inartificial vehicles, ploughs, and harrows formerly in use being scarcely to be met with except in districts little capable of being brought into profitable agricultural production. The breed of every kind of cattle has been improved during the last forty or fifty years, to a degree that scarcely could have been anticipated at the commencement of the period. Dairies are numerous and highly productive. Butter is the produce chiefly attended to, and large quantities are prepared for export. In 1858 the stock of the country included 14,197 horses, 69,370 cattle, 80,012 sheep, and 32,921 pigs; and the total value of live stock was L.689,000.

From the preceding statement it may easily be inferred that the character of the population is almost exclusively agricultural. The only place in which manufactures have been introduced is Mountmellick. Several branches of the woollen, linen, and cotton trade have been undertaken there, but without much success; coarse woollens and cotton for the supply of the surrounding districts being the only kinds fabricated. Tanning is carried on to some extent; flour-mills are large and numerous; and there are some extensive distilleries and breweries. In 1852 an extensive establishment was formed here for the manufacture of sugar from beet-root, but subsequently the experiment proved unprofitable, and is not likely to be repeated, it being evident that the article cannot be successfully manufactured in competition with colonial and foreign sugar. The Grand Canal, a branch of which runs from Monasterevan to Mountmellick, conveys much of the produce of the county to Dublin, either for sale there or for export. The Barrow serves the same purpose with respect to Waterford. The Great Southern and Western Railway crosses the county from N.E. to S.W., having stations at Portarlington, Maryborough, Mountrath, &c., and connecting it with Dublin, Limerick, and Cork.

There are many remains of ancient edifices, both ecclesiastical and military. Amongst the most remarkable of the former are the extensive ruins of the abbey of Aghaboe, once the seat of the bishopric of Ossory; the ruins of Aghmacart, and of several others of lesser note. The site of the abbey of Timahoe can be ascertained only by the pillar-tower there, which is supposed to have stood in its immediate vicinity. Of the military antiquities, the most ancient is a fortress placed on the summit of a hill in the south-west of the county, and called Bawnachra; it consists of a circular inclosure surrounded by a rampart and fosse. The ancient fortress of Dunamase, situated about four miles south-east of Maryborough, on the summit of a precipitous hill rising abruptly from the middle of a large plain, and once the chief residence of the O'Mores, presents a very picturesque appearance. Lea Castle, the fine ruins of which stand on the right bank of the Barrow, about 2 miles below Portarlington, was formerly a place of considerable strength, erected by the Fitzgeralds in 1260, burnt by Edward Bruce in 1315, afterwards rebuilt, and finally reduced to ruins by Cromwell's army in 1650. Borris-in-Ossory on the Nore, and Castlecuffe in Tinnehinch, built by the celebrated republican leader Sir Charles Coote, were also places of considerable strength. Amongst the modern mansions are those of the Earl of Portarlington at Emo, and of Sir Charles Coote, at Ballyfin, near Mountrath, two of the finest modern structures in the Italian style to be found in the kingdom.

Maryborough, the county town, situated nearly in the centre of the county, presents few features to arrest attention. It was a borough entitled to send representatives to Parliament; but this, the only important privilege to a small town, was abolished at the Union, the other corporate functions decayed, and were extinguished by the Municipal Corporations Act. The town is now under the superintendence of town commissioners. The chief buildings are the county court-house, the jail, the infirmary, and the district lunatic asylum. The population in 1851 was 2635. That of the other towns having upwards of 1000 inhabitants each was in the same year respectively as follows: Mountellick, 3657; Portarlington, originally a settlement of French refugees, and formerly of some note as a place of elementary education, 2728; Mountrath, 2101; Graigue, which is, strictly speaking, a suburb of Carlow, though in a different county, 1527; Ballynakill, 1109; Stradbally, near which is the Dun of Clopoke, an isolated rock perforated by subterraneous cavities, 1326; and Abbeyleix, which, though amongst the smallest, is the neatest in external appearance, 1341.

QUEENSFERRY, South, a parliamentary and royal burgh of Scotland, in the county of Linlithgow, on the right bank of the Forth, 9 miles N.W. of Edinburgh. It is an irregularly-built place, containing a curious ancient chapel, a new church, and a meanly-built town-hall. The town has very much declined in importance, having been dependent chiefly on the ferry, which was once the principal means of communication between Edinburgh and the north, but which has been in a great measure superseded by that from Granton to Burntisland. Queensferry is said to derive its name from Margaret, Queen of Malcolm III., who used to embark here. Pop. (1851) of the parish, 1165; of the parliamentary burgh, 720.

QUEENSTOWN, or, as it was formerly called *Cove of Cork*, a seaport and market town of Ireland, in the county of Cork, on the south side of Great Island, in Cork harbour, 14 miles E.S.E. of Cork, and 167 S.W. by S. of Dublin. Built upon the steep side of a hill rising from the water, it has a very fine appearance, its streets running parallel to the shore, and rising one above another. Most of the houses are well built, and some, as a defence against storms, are faced with slates. Besides the parish church, a fine edifice erected in 1812, there are Roman Catholic and Wesleyan places of worship, a market-house, jail, national schools, public library, reading-rooms, hospital, dispensary, &c. In the harbour, opposite to Queenstown, stands Spike Island, which contains artillery barracks and a convict establishment; and there are also smaller islands, with powder magazines, and an ordnance depôt. The pier of Queenstown, which was built in 1805, is used as a public walk, and commands a fine view of the harbour. There are no manufactures or commerce here; and the town has risen to its present size since the last French war, when it was an admiral's station. Before that time it was nothing but a small fishing village. It is now much resorted to as a bathing-place, especially by invalids. The name of Queenstown was given to it in 1849, in honour of the visit of Queen Victoria. Communication is kept up by steam between Queenstown and Cork. Pop. (1841) 5142; (1851) 11,428.

QUELPAERT, an island in the Pacific, about 60 miles off the south coast of Corea, N. Lat. (of Beaufort Island) 33. 9. 7., E. Long. 126. 56. 5.: length, 45 miles; greatest breadth, 12. The surface is mountainous; and there is a peak in the centre as high as 6544 feet above the sea. Volcanic in its origin, the island is covered with dense forests in the higher regions; but the soil is in general light, and produces corn but scantily. The houses of the inhabitants resemble those of the Loo-Choo islanders; and there is a town called Moggan on the N. coast. Quelpaert is supposed to be used as a penal settlement of Corea.

QUENTIN, St, a town of France, capital of an arrondissement in the department of Aisne, on the Somme, 87 miles N.E. of Paris. It is built on the sides and top of a hill, and surrounded by public walks, which occupy the place of the ancient fortifications. In a spacious square near the centre stands the town-hall, a handsome and richly-ornamented edifice. The cathedral, a large structure, 416 feet long in the interior, and 212 feet high, is a fine specimen of pure Gothic architecture, and has some fine painted glass in several of the windows. The town contains also a court-house, theatre, public library of 14,000 volumes, infirmary, and several hospitals. St Quentin is the centre of the manufacture of linen cloth, which is carried on extensively in the surrounding country. Cotton fabrics are also made; and there are many bleach-fields in the vicinity. The trade of St Quentin, besides the manufactures of the place, includes corn, fruits, liquorice, flax, and colonial produce. It is much facilitated by the canal of St Quentin, which unites the waters of the Oise, Somme, and Scheldt. A battle was fought under the walls of the town in 1557, between the French and the Spaniards, in which the latter gained a complete victory. Pop. (1856) 26,887.

QUERETARO. See Mexico.

QUERINI, or Quirini, Angelo Maria, a learned cardinal, was born at Venice in 1680, and was educated at the college of the Jesuits in Brescia. The early part of his career was devoted to the enthusiastic study of letters. Settling down in Florence at the age of seventeen, as a Benedictine monk, he availed himself of every means to satisfy his craving for knowledge. His quiet hours within the walls of the abbey were engrossed with the cultivation of the liberal sciences. His intervals of recreation in the city were passed in the society of some of the most learned men of the day. The progress of time only increased his literary ardour. Bent upon seeing the world, and upon holding personal converse with the great spirits of the age, he set out in 1710 on a tour through Europe. He passed through Germany, the Netherlands, England, and France, visiting the chief literary men of each country; and returned home in 1714, greatly advanced both in acquirements and in reputation. With a mind so thoroughly cultivated, Querini could scarcely fail to attract the interest of the Holy See. Accordingly, in no long time there was opened up before him a way of promotion to some of the highest offices in the church. In 1723 he was appointed archbishop of Corfu. In 1728 he was translated to the see of Brescia, and created a cardinal. Not long afterwards the office of librarian of the Vatican was conferred upon him. He would also have been promoted to the lucrative bishopric of Padua, had he not preferred to spend his remaining days among his attached Brescian diocesans. Cardinal Querini, in his high position, now proved himself a beneficent patron of learning. He founded and endowed a public library at Brescia. He presented one large collection of books, and another of medals, to the library of the Vatican. Nor was his liberality at all influenced by party feelings. Authors of every class found him ready to supply them with books, manuscripts, and notes, for the composition of their works. In fact he had come to be recognised throughout Europe as a benefactor in the world of letters, when he was suddenly cut off by apoplexy in 1755.

The following is a list of Querini's most important works:—*Primordia Corcyrae*, 4to, Brescia, 1738; *Specimen Litteraturæ Brixianæ*, 4to, Brescia, 1739; *Pauli II. Vita*, 4to, Rome, 1740; and a selection of his own letters, in ten books, 4to, Brescia, 1742–49.

QUESADA, a town of Spain, Andalucia, in the province, and 38 miles E. of Jaen. It is an ill-built place, with a church, hospital, school, court-house, and the remains of an old fort, now used as a prison. Flour, oil, and soap are manufactured here; and there is some trade in corn, fruit, &c. Pop. 4503.

QUESALTENANGO, a town of Guatemala, capital of a department of the same name, on the small river Samala, 88 miles W.N.W. of Guatemala. It is large and well built, being second only to the capital in point of size. In the centre is a large market-place, with a fountain in the middle. The streets are straight, and the houses large and handsome. Among the churches in the town, there is one of large size and imposing appearance; and there is also a good town-hall. Some trade is carried on in wheat, sugar, woollen and cotton fabrics, &c. Pop. 20,000, many of whom are Indians.

QUESNAY, François, a physician of considerable eminence, but who is chiefly known as an ingenious inquirer into the constitution of society, and as the founder of the sect of political philosophers known by the name of Economists.

The accounts of the life of this distinguished person, which, unlike that of most literary men, abounded in incident and adventure, are exceedingly meagre and contradictory. Neither the place of his birth nor the condition of his parents has been well ascertained; but the accounts apparently most entitled to credit state that he was born at the village of Ecquivilly in the Isle de France in 1694; and that his father was either a common labourer, or a small proprietor who cultivated his own little property.[1] His humble origin is indeed evident from the fact mentioned by all his biographers, of his early education having been almost entirely neglected, and of his being constantly occupied, until his fourteenth or sixteenth year, in the sports or labours of the fields, without being either sent to school or taught to read. But although placed in such unfavourable circumstances, young Quesnay was imbued with an ardent love of knowledge, and with a strong desire to emerge from the obscure station in which he had been brought up. The *Maison Rustique* of Liebaut was the first book that came into his hands; and he is said to have learned to read it by the assistance of lessons given him by a gardener of the village. The perusal of this book, which seems to have had a material influence over his future studies, awakened his latent powers, and stimulated him to make further efforts to extend his information. Having acquired a competent knowledge of his vernacular tongue by the eager reading of such French books as came into his hands, he next applied himself to the study of the dead languages; and speedily attained, partly by the slender assistance of a self-dubbed surgeon of the village, but chiefly by his own industry, to a tolerable proficiency in Latin and Greek.

Quesnay now resolved, in opposition to the wishes of his parents, and especially of his mother, to devote himself to the profession of surgery, and received the rudiments of his instruction in that art from the village doctor who had assisted him in his philological studies. But the pupil very soon surpassed the master; and when the latter applied to be admitted into the *Maitrise*, or Corporation of Surgeons, he presented, as testimonials of his skill in his profession, and of his capacity to practise it with advantage, some Essays written by Quesnay, and which were received with much applause. Quesnay was not aware of this trick; but soon after its occurrence he left his paternal village, and set out to prosecute his studies at Paris. We are not informed by what means he supported himself in that city, nor how long he remained there; but his indefatigable industry and zeal enabled him to make great progress in his studies, whilst his merit and modesty procured him several friends. Besides attending prelections on the various branches of surgery, and the different hospitals, he found leisure to devote some portion of his time to metaphysical researches, and the study of philosophy, for which the perusal of the *Recherche de la Vérité* of Malebranche had given him a taste. Nay, such was the activity and vigour of his mind, that having accidentally met, during his stay in Paris, with the celebrated M. Cochin, of the Royal Academy of Painting, he put himself under his tuition; and we are told that he profited so well by the few lessons he received, as to be able not only to take remarkably good likenesses, but to design and engrave, with his own hand, the various bones of the human skeleton, in a manner which would not have disgraced the most skilful artists.

On finishing his studies at Paris, Quesnay formed the design of establishing himself as a surgeon in Mantes, a considerable town of his native province, and presented himself to the surgeons of its *Maitrise* for examination. But they refused, from jealousy, as is alleged, of his talents, to admit him to trial. He was thus laid under the necessity of returning to Paris, where he passed his examinations with éclat; and in 1718 received letters ordering him to be admitted into the Corporation of Mantes.

Having established himself at Mantes, his reputation soon extended itself. He was employed by some of the first families of the neighbourhood, and, amongst others, by that of the Marshal de Noailles, Duc de Villeroi, who persuaded him to leave his residence in the country, and to accompany him to Paris as his surgeon, as nearly as we can collect in 1729 or 1730. An incident not long afterwards occurred which had the most material influence over his future prospects and life. Having accompanied the Duc de Villeroi to the house of the Comtesse d'Estrades, Quesnay remained behind in the carriage whilst the duke went in to visit that lady, who, during the interview, was suddenly seized with an epileptic fit. Quesnay being called in, and perceiving the nature of the attack, with singular presence of mind ordered the duke and the other attendants out of the room, and managed so well as to succeed in concealing the nature of the malady. The comtesse was so much pleased with this dexterity and address, that she lost no time in recommending Quesnay to her all-powerful friend, Madame d'Etioles, afterwards Marchioness de Pompadour. The latter made him her physician; and, besides obtaining for him apartments at Versailles, procured him, in 1737, the place of surgeon in ordinary to the king.[1]

---

[1] It is stated in the "Eloge Historique" of Quesnay, in the *Mémoires de l'Académie des Sciences* for 1774, that he was the son of an *advocat en Parlement* at Montfort, and that he was born at Merey. But it is difficult to suppose, had his father been in such a station, that his education should have been so entirely neglected. In the brief but interesting notice of Quesnay given by Mr Crawford in a note to the *Journal* of Madame du Hausset, femme-de-chambre of Madame de Pompadour, et *l'amie* de Quesnay, in the *Mélanges d'Histoire et de Littérature* (p. 276), he is stated to have been the son of a labourer. This also is the statement of the *Encyclopédie Méthodique*. According to the notice prefixed by Dupont to the "Eloge" of M. Gournay in the third volume of the *Œuvres de Turgot*, Quesnay was the son of a peasant-proprietor.

Quesnay was shortly afterwards appointed secretary to the Royal Academy of Surgery, established in 1731; and, besides several articles on particular branches of surgery, he contributed the Preface to the first volume of its *Mémoires*, which has always been reckoned peculiarly valuable for its profound and discriminating observations on the respective uses of theory and observation in the physical sciences, and on the assistance they reciprocally lend to each other.

Having from an early period been much subject to the gout, and becoming in consequence less able to discharge his duties as surgeon, Quesnay took the degree of Doctor of Medicine in 1744; and was soon afterwards appointed, through the influence of his powerful patroness, to the important place of consulting physician to the king. In this capacity he attended Louis XV. in the campaigns of 1744 and 1745, and, amid the distractions of a camp, collected and prepared the greater part of the materials for his *Traité de Fièvres*, published in 1753.

His appointment as physician to the king was preceded by the grant of letters of nobility, issued on the recovery of the Dauphin from an attack of small-pox. Louis, who was much struck with the justice and solidity of Quesnay's remarks, familiarly called him *son penseur*, and gave him, in allusion to this title, three pansey flowers (in French *pensées*) for his arms, with the motto "*Propter cogitationem mentis.*"

The leisure Quesnay now enjoyed enabled him to prosecute his studies with greater assiduity. In 1747 he republished an enlarged edition, in 3 tomes 12mo, of his *Essai Physique sur l'Economie Animale*, originally published in 1736; in 1748 he published an *Examen Impartiel des Contestations des Médécins et des Chirurgiens de Paris;* in 1749 he published a *Mémoir sur la Sagesse de l'Ancienne Législation de la Chirurgie en France*, and two separate treatises in 12mo, the one on *Suppuration*, and the other *De la Gangrène;* in 1750 he republished his *Traité des Effets et de l'Usage de la Saigné*, written during his residence at Mantes, and originally published in 1730; and in 1753 he published his *Traité des Fièvres Continués*, 2 tomes 12mo.

These works have all been held in high estimation; and an excellent judge has given it as his opinion that "The *Traité de la Gangrène* is by far the most valuable publication which we yet possess upon this subject." Every page of this work, he adds, "is distinguished by the same talent for accurate observation and perspicuous arrangement which are so remarkable in all the other writings of this celebrated author." (Thomson's *Lectures on Inflammation*, p. 502.)

The *Traité des Fièvres* was the last of Quesnay's professional works. He appears to have thenceforth comparatively abandoned his medical studies. At no period, indeed, had he allowed them to occupy exclusively his attention; and he now devoted himself in preference to other, and, if possible, still more interesting inquiries. He had always entertained a strong predilection for agricultural pursuits, the effect, perhaps, of his situation in early life; and this, combined with the speculative and metaphysical cast of his mind, seems to have led him to those peculiar notions respecting the paramount importance of agriculture as a source of wealth, and the constitution of society, which have rendered his name so celebrated in the history of economical science. The articles "Fermier" and "Grains" in the *Encyclopédie*, published in 1756 and 1757, contain the earliest development of his views on this subject. They are both written with great ability, and display an intimate acquaintance with the subject, considerable reading, and great powers of analysis. In the article "Grains" the distinction between the gross and nett produce (*produit total* and the *produit net*,)—between the productiveness of agriculture and the supposed unproductiveness of other employments, with the doctrine of the unrestricted freedom of commerce, and most of the other leading principles in the theory of the Economists, are distinctly stated, and illustrated with much ingenuity. The *Tableau Economique* and the *Maximes Générales du Gouvernement Economique*, annexed to it under the title of *Extraits des Economies Royales de M. de Sully*, were printed by command of the king at Versailles, in the year 1758, with the following very remarkable epigraph for a work brought forth under such auspices,—"Pauvres paysans, pauvre royaume; pauvre royaume, pauvre souverain." The Maxims, which contain a short but comprehensive abstract of Quesnay's system, were reprinted, together with an analysis of the Table, and a selection from various articles contributed by Quesnay, in explanation and defence of his peculiar doctrines, to the *Journal d'Agriculture*, and the *Ephémérides du Citoyen*,[2] in the collection of Quesnay's economical works, entitled *Physiocratie, ou Constitution Naturelle du Gouvernement le plus Avantageux au Genre Humain*, edited by his friend and scholar Dupont in 1767.

We have elsewhere entered at considerable length into an examination of the speculations of Quesnay and his followers, with respect to the constitution of political societies and the sources of public wealth. (See ECONOMISTS, and POLITICAL ECONOMY.) That there is a good deal of error in them must be allowed; but this is far more than countervailed by the many just, discriminating, and original views and important discoveries which they contain. Perhaps, however, the principal merit of Quesnay and his followers does not consist so much in the discoveries they made, as in their having been the first philosophers who distinctly perceived that the institutions of society should always harmonize with the natural principles on which it is founded, or, as they termed it, with the *ordre naturel et essentiel des sociétés politiques.* According to them, economical science is "*L'étude et la démonstration des loix de la nature rélatives à la subsistence et la multiplication du genre humain.* L'observation universelle de ces loix est l'intérêt commun et général de tous les hommes. La connaissance universelle de ces loix est donc le préliminaire indispensable et le moyen nécessaire du bonheur de tous." (*Ephémérides du Citoyen*, 1769, No. ii., p. 13.) It is to be regretted that, in investigating these laws, they proceeded too much upon abstract and speculative principles, without sufficiently attending to the effects of particular institutions, and to the various phenomena manifested in the progress of society. But notwithstanding the defective mode in which they conducted their researches, they succeeded in establishing and elucidating many important principles; and there is certainly much more reason to wonder at the general correctness of their conclusions, than to feel surprised at the errors into which they fell. Quesnay and his disciples established, that society either is or should be formed to secure the greatest possible advantage to its members; that the security of property and the freedom of industry are its essential bases; and that, instead of interfering to regulate the pursuits of individuals, the proper business of the politician is to protect the equal rights and liberties of all, and to secure the utmost freedom of competition in every department of industry. And though it be undoubtedly true that most of these principles had been pointed out by previous writers, Quesnay and his school have the merit of being the first who showed their dependence on each other, and who, by presenting them in a systematic and consecutive form, were enabled to give a scientific demonstration of the injustice and impolicy of such institutions as ignorance or mistaken views of national interest had established in opposition to them.

---

[1] This incident is related by Crawford, *Mélanges*, p. 276, and is referred to by Marmontel.

[2] The *Ephémérides du Citoyen*, begun in 1767, was for a few months conducted by the Abbé Baudeau, and then by Dupont. It appeared monthly, and two numbers make a considerable 12mo volume. The authors were disciples of Quesnay, and zealous Economists. Their discussions embraced the moral and political sciences, many branches of which they have treated with much ability and acuteness. There is a valuable Eloge of Quesnay in one of the numbers for 1775, written by Count d'Albon. The following extract from the *approbation* given by the *Censeur* to the third number for 1770 is curious:—"J'exhorte de nouveau les auteurs de ce *Journal*, à résister à la tentation de critiquer. Le bonheur du citoyen tient à sa confiance. On peut et l'on doit quelquefois avertir en secret ceux qui sont préposés à l'administration. Mais ou ne doit prêcher aux particuliers que leur propre réforme, et non celle de l'état."

In the article POLITICAL ECONOMY an attempt has been made to show the fallacy of Quesnay's opinion with respect to agriculture being the only source of wealth; and the experience of all ages sufficiently proves that the *despotisme légal*, in the hands of an hereditary monarch, without *contreforces* of any kind, which he strangely supposed was the best of all possible governments, is about the very worst.[1]

Notwithstanding his great age, and the sufferings he experienced from almost incessant attacks of the gout, the activity of Quesnay's mind continued unimpaired. "*Il a*," said one of his friends, "*une tête de trente ans sur un corps de quatre-vingts*." He contributed, subsequently to the publication of the *Physiocratie*, many acute and able articles to the *Ephémérides du Citoyen*, and continued wholly occupied with these studies, and with mathematics, to which he latterly began to pay considerable attention, until his death, which took place at Versailles in December 1774, in the eightieth year of his age.

Quesnay possessed inflexible integrity, a nice sense of honour, and great prudence and discretion. Though highly esteemed by the king, and long resident at court, he never intermixed in the intrigues of which it was the constant theatre. No one ever scrupled to express himself freely in his presence; nor was this confidence ever betrayed. "Il récevoit chez lui des personnes de tous les partis, mais en petit nombre, et qui toutes avoient une grande confiance en lui. *On y parloit très hardiment de tout; et ce qui fait leur éloge et le sien, jamais on n'a rien repété*."[2] To the utmost frankness and sincerity he added the easy address and polish of a courtier and the intelligence of a philosopher. No man could be less solicitous of distinguishing himself, or more careful not to offend the self-esteem of others. His conversation was animated, without the least effort at brilliancy. So much, indeed, was he averse from every appearance of pretension, that he was in the habit of veiling the most profound remarks and observations under the form of apologues, which generally referred to some subject connected with rural affairs, to which he was always particularly attached. He was most indulgent to the faults and errors of others, provided they were unalloyed by any taint of artifice or baseness, for which he never hesitated, whatever might be the rank of the party, to express the utmost contempt. Quesnay was truly a patriot and a philosopher; and it would be difficult to produce another instance of one who, having lived long in a profligate and luxurious court, unsullied by its vices and aloof from its contentions, preserved to an extreme old age all those generous and kindly feelings, with that unobtrusive but ardent zeal in the cause of humanity, and that love of speculation and profound inquiry, which distinguished his earlier years.

"Quesnay," says Madame du Hausset, "étoit un grand génie, suivant l'opinion de tous ceux qui l'avoit connu, et de plus un homme fort gai. Il aimoit causer avec moi de la campagne; j'y avois été élevée, et il me faisoit parler des herbages de Normandie et du Poitou, de la richesse des fermiers, et de la manière de cultiver. C'étoit le meilleur homme du monde, et la plus éloigné de la plus petit intrigue. Il étoit bien plus occupé à la cour de la meilleure manière de cultiver la terre que de tout ce que s'y passoit." (*Mélanges*, p. 343.)

"Tandis," says Marmontel, "que les orages se formoient et se dissipoient au-dessus de l'entresol de Quesnay, il griffonnoit ses axiomes et ses calculs d'économie rustique, aussi tranquille, aussi indifférent à ces mouvemens de la cour, que s'il en eût été à cent lieues de distance. Là bas, on déliberait de la paix, de la guerre, du choix des généraux, du renvoi des ministres; et nous, dans l'entresol, nous raisonnions d'agriculture; nous calculions le produit net, ou quelquefois nous dînions gaiement avec Diderot, d'Alembert, Duclos, Helvétius, Turgot, Buffon; et Madame de Pompadour, ne pouvant pas engager cette troupe de philosophes à descendre dans son salon, venoit elle-même les voir à table, et causer avec eux." (*Memoirs d'un Pere.*, i. 286.)

Dr Smith was well acquainted with Quesnay. He frequently met him during his residence at Paris in 1766; and whilst he bears the most honourable testimony to the "modesty and simplicity" of his character, he has pronounced his system to be, "with all its imperfections, the nearest approximation to the truth that has yet been published on the subject of political economy." (*Wealth of Nations*, p. 307.) So highly, indeed, was Smith impressed with a sense of his merits as a man and a philosopher, that it was his intention, had he not been prevented by Quesnay's death, to have inscribed to him the *Wealth of Nations*. (Dugald Stewart's *Account of the Life and Writings of Dr Smith.*)

Quesnay had a son by his wife, to whom he was united when at Mantes. He gave him an excellent education; and exhibited a striking proof of his disinterestedness by constantly refusing to solicit for him any place or situation under government. This son ultimately settled in the country, on an estate near Beauvoir. Turgot gave one of Quesnay's grandsons a place in the administration; and another entered the army, and acted as captain of infantry at the battle of Jemappes.

Few men have been more esteemed by their friends than Quesnay, or more ready to do all in their power to advance their interests. Mercier de la Rivière, the author of the work *Sur l'Ordre Naturel et Essentiel des Sociétés Politiques*, seems to have occupied the chief place in his esteem, and was looked upon by him as the only person in France qualified to conduct the administration of the finances. He was also much attached to the Marquis de Mirabeau, Turgot, Dupont, the Abbé Baudeau, St Péravy, and other leading Economists, who willingly acknowledged him for their master, and enthusiastically exerted themselves to defend and to propagate his docrines. "The Economists were in reality, and not merely in appearance, a sect of philosophers:

---

[1] We are at a loss to conjecture the grounds on which Chalmers has affirmed (*Biographical Dictionary*, vol. xxv., art. "Quesnay"), that the "Economists abused their influence by circulating democratical principles." It would be quite as correct to say that Locke and his followers abused their influence by circulating despotical principles.

[2] "Journal de Madame du Hausset," in the *Mélanges*, &c., p. 277. A striking instance of the confidence placed by the most opposite parties in Quesnay is given in the second volume of Marmontel's *Memoirs*.

Secta fuit, servare modum, finemque tenere
Naturamque sequi, patriæque impendere vitam,
Nec sibi, sed toti genitum se credere mundo.

They acted from an honest zeal for the truth, and not from fashion, eccentric tastes, or the love of singularity; their sole object was to enlighten and improve mankind; and to them, amongst political inquirers, belongs the rare praise of having first pointed out the natural order of things, or the observed course of nature in the conduct of the world, as the example and guide of human policy." (J. R. M.)

QUESNE, Abraham, *Marquis de*, admiral of the naval forces of France, and one of the greatest men of the seventeenth century, was born in Normandy in the year 1610. He contributed to the defeat of the naval power of Spain at Gattari; he was dangerously wounded before Barcelona in 1642; and having entered into the service of the Swedes, he became vice-admiral, and entirely defeated the Danes, killing their admiral, and taking his ship. He was recalled to France in 1647, and commanded the squadron sent to Naples. The naval affairs of France being much decayed, he fitted out divers ships for the relief of the royal army that blockaded Bordeaux, which was the principal cause of the surrender of the town. He was very fortunate in the wars of Sicily, where he defeated the Dutch thrice, and killed their admiral De Ruyter. He also obliged the Algerines to sue in a very humble manner for peace from France. In short, Asia, Africa, and Europe felt the effects of his valour. He was a Protestant; yet the king bestowed on him the land of Bouchet, and, to immortalize his memory, gave it the name of that great man. He died in 1688.

QUEUE. See Heraldry.

QUEVEDO Y VILLEGAS, Francisco Gomez de, a Spanish writer of considerable celebrity, was the contemporary of Lope de Vega and Cervantes, and was born at Madrid in 1580. His father, though descended from a family in that mountainous region to the north-west of Spain, occupied at the time of his birth some office of dignity at the court of Philip II. At the age of fifteen young Quevedo graduated in theology at the university of Alcalá, where he laid a foundation broad enough for universal scholarship. He must have been possessed of extraordinary natural endowments, as well as of extreme industry. On his return to Madrid he mixed with the distinguished scholars and fashionable cavaliers of his time. In "an affair of honour" in which he had the ill-luck to be engaged, he killed a person of rank, fled to Sicily, was invited to the splendid court of the Duke of Ossuna, viceroy to Philip III., and was subsequently employed in important affairs of state, which demanded on numerous occasions personal courage and involved personal risk. On the conclusion of his master's administration in Sicily, Quevedo was despatched to Madrid in 1615 as a sort of plenipotentiary, where he was very graciously received. He returned to the duke, who was now in Sicily, with a pension of 400 ducats, and was raised to the dignity of minister of finance. He discharged this duty with eminent skill and honesty; and in 1617 he was made a knight of the Order of Santiago. In 1620 the duke fell from power, and Quevedo endured a detention of three years and a half in his patrimonial estate of Torre de Juan Abad. He refused various offices of state, and was content with the merely titular rank of Secretary to the King. He had long had a desire to betake himself to letters, and he did so for the rest of his life. In 1634 he married; but was soon left alone by the death of his wife. In 1639, in consequence of some satirical verses which were placed under the king's napkin at dinner, and which were hastily attributed to Quevedo, he was seized with great suddenness and secrecy, and was rigorously confined for upwards of four years in the royal convent of San Márcos de Leon. Here, in a damp and unwholesome cell, his health was wasted beyond all recovery: his personal property likewise melted away, until he was obliged to depend on charity for his support. In a haughty yet heart-rending letter written to Olivarez, he tells him despairingly, "No clemency can add many years to my life; no rigour can take many away." The hour of the favourite's disgrace came at last, and Quevedo was free. It was already admitted that another had written the verses; but it was too late. Quevedo failed in his endeavour to recover his lost property; and, unable to subsist in the capital, he retired to the mountains from which his race was sprung, where, worn out by suffering and exhausted by trial, he died in 1645.

The works of Quevedo which have come down to us show him to have been a fruitful and an industrious writer. He tried his hand in all manner of departments, from theology and metaphysics down to stories of vulgar life and wild gypsy ballads. Many of his writings are still in manuscript, in the national library of Madrid and in other collections, public and private. He seems to have published nothing with his name except his meagre translations of Epictetus and Phocylides. His first appearance as an author was probably in *The Flowers of Illustrious Poets* of his friend Pedro de Espinosa. After his death, Gonzalez de Salas published, in 1648, the first part of such of his poetry as could conveniently be reached; and his nephew, Pedro Alderete, issued the rest in 1670, in a very careless manner, under the conceited title of *The Spanish Parnassus, divided into its Two Summits, with the Nine Castilian Muses.* Sonnets and ballads are the most numerous, but there are likewise abundance of odes, satires, and idyls. Many of his lighter ballads, such as those of the Gypsies, have attained an unbounded popularity among the peasants, and are still to be heard sung to the guitars thoroughout the whole of Spain. His burlesque sonnets, in imitation of the Italian, are considered the best in the language. But besides the indecency of much of his poetry, he made use of words and phrases that are low and essentially unpoetical. In 1631 he published a small volume entitled *Poems by the Bachiller Francisco de la Torre*, which are now generally ascribed to his own pen. The works, however, on which Quevedo's fame mainly rests, both at home and abroad, are in prose. Passing by those on theology and metaphysics, we come to *The History and Life of the Great Sharper, Paul of Segovia*, first printed in 1627. It is written in the *picaresco* style of Mendoza's *Lazarillo de Tormes*, and is overrun with conceits, puns, and a reckless, fierce humour. It teems with wit, and most cruel sarcasm against all orders of society. As a satire it is perhaps too hard and unrelenting to be considered at all amusing. This, indeed, is the charactar of most of his other prose satires, and especially his *Visions*, published in 1635. As an instance of that mixture of the solemn and ludicrous in which he so much delighted, the reader will obtain as good a specimen as can be given in his *Dream of Skulls* or *Dream of Judgment.* Everywhere he exhibits a bold, original, and independent spirit; and his personal sufferings may have had much to do with his satirical bitterness and the severity of his sarcasm.

A somewhat diffuse Life of Quevedo was printed at Madrid in 1663 by Don Pablo Antonio de Tarsia, a Neapolitan, and is inserted in the tenth volume of the best edition of Quevedo's works, that of Sancha, Madrid, 11 vols. 8vo, 1791–94. A much more satisfactory Life is to be found in Baena's *Hijos de Madrid*, tom. ii., pp. 137–154.

Quevedo's *Visions* were freely rendered into English in 1668 by Sir Roger l'Estrange; a number of his tales were translated into English by Stevens in 1707, and by Pineda in 1734. The latter is the basis of the Edinburgh translation of the *Visions*, &c., 3 vols., 1798. (See Ticknor's *History of Spanish Literature*, vol. ii., c. xix.)

QUID PRO QUO, in law, denotes the giving one thing of value for another; or the mutual consideration and performance of both parties to a contract.

Quid pro Quo, *Qui pro Quo*, is also used in physic to express a mistake in the physician's bill, where *quid* is written for *quo*, that is one thing for another; or of the apothecary, in reading *quid* for *quo*, and giving the patient the wrong medicine. Hence the term is in general extended to all blunders or mistakes committed in medicine, either in the prescription, the preparation, or the application of remedies.

QUIETISM. See Mysticism.

QUILIMANE. See Mozambique.

QUILLET, Claude, an eminent Latin poet, was born at Chinon in Touraine in 1602, and practised physic there with reputation; but having declared against the pretended possession of the nuns of Loudun, in a manuscript treatise, the original of which was deposited in the library of the Sorbonne, he was obliged to retire into Italy, where he became secretary to the Marshal d'Estrées, the French ambassador at Rome. In 1655, Quillet having published in Holland a Latin poem entitled *Callipædia*, under the name of "Calvidius Lætus," he there inserted some verses against Cardinal Mazarin and his family; but that churchman making him some gentle reproaches, he retrenched what related to the cardinal in another edition, and dedicated it to him, Mazarin having, before it was printed, given him an abbey. He died in 1661, aged fifty-nine, after having given Ménage all his writings, and 500 crowns to pay the expense of printing them; but the Abbé took the money and papers, and published none of them. A third edition of his poems, with a number of other pieces, was published in London in 1708, 8vo. The *Callipædia* was translated into English verse by Nicolas Rowe, London, 1710.

QUILLOTA, a town of Chile in the province of Aconcagua, in a fertile valley 23 miles N.E. of Valparaiso. It is chiefly important on account of the copper mines in the vicinity, which are considered the richest in the country. The town suffered much from an earthquake in 1823; and also on other occasions. Pop. 8000.

QUILOA, or Keelwa, a seaport-town of Zanguebar, on the E. coast of Africa, on an island about 10 miles long and 6 broad, 225 miles N. of Mozambique; S. Lat. 8. 57., E. Long. 39. 47. From the middle of a grove of palms rise the whitewashed flat-roofed houses of the town, and the domes and minarets of its mosques. The streets are narrow, and the buildings generally substantial. Some remains of former fortifications are still in pretty good preservation; and there is a fort capable of containing a strong garrison, though mounted with no guns. The harbour is large and deep, accessible to vessels of any size. Quiloa was once a place of much importance; and its monarchs held sway over the country as far south as Sofala. It was taken and burned by the Portuguese in 1505, but abandoned by them soon after, on account of its unhealthiness. It was subsequently rebuilt, and has recovered some degree of its former prosperity, being subject now to the Imam of Muscat. Pop. from 6000 to 8000.

QUILON, a seaport-town of India, in the native state of Travancore, presidency of Madras, 385 miles S.W. of Madras, and 740 S.E. of Bombay. There is here a British cantonment, containing a barrack and an hospital. The town has also a jail under the native authorities; and an Episcopal church has been erected some years ago. Communication is carried on with Trivandrum, the capital of Travancore, by means of canals running parallel to the shore; and similar means of transit extend in the opposite direction northwards. The chief productions of Quilon are timber, cocoa-nuts, pepper, ginger, and coffee. There is good anchorage in a bight about 3 miles from the fort. Pop. estimated at 20,000.

QUIMPER, a town of France, capital of the department of Finistère, on the slope of a hill at the confluence of the Eir and the Odet, 134 miles N.W. of Nantes, and 330 W. of Paris. It has an antique appearance; and there are still some remains of its ancient walls and towers. The older part of the town is ill built; but the more modern quarter contains many fine houses, especially along the quay which lines the right bank of the Odet. The cathedral is a large and stately edifice, with a finely-sculptured portal and two massive towers. There are more than one other church, a large college, a military hospital, public baths, and a prefect's house, behind which there is a fine promenade leading to the top of a wooded hill. Quimper contains potteries, tanneries, breweries, &c. Fishing and ship-building are also carried on; and there is a considerable trade in corn, wine, brandy, fish, cattle, wool, hemp, flax, &c. Pop. (1856) 9896.

QUIMPERLÉ, a town of France, in the department of Finistère, at the confluence of the Isole and Ellé, 57 miles S.E. of Brest. It has a picturesque situation among high hills; and contains a curious old round church, a large Benedictine convent (now the residence of the mayor), Capuchin and Ursuline convents, a college, and a court of justice. Leather, paper, and wooden shoes are made here; and there is some trade in these articles, corn, and cattle. Vessels of considerable size can come up to the town, and discharge their cargoes at a spacious quay lined with good warehouses and other buildings. Pop. (1856) 5902.

QUIN, James, a celebrated performer on the English stage, was born in King Street, Covent Garden, London, on the 24th of February 1693. He was intended for the bar; but preferring Shakspeare to the statutes at large, he, on the death of his father, when it became necessary for him to do something for himself, appeared on the stage at Drury Lane. For this profession he had many important qualifications. He had an expressive countenance, a majestic figure, a piercing eye, and a clear, full, melodious voice. In 1720 he first displayed his comic powers in the character of Falstaff, and soon afterwards appeared to as great advantage in Sir John Brute; but it was upon Booth's quitting the stage that Quin showed to most advantage, in the part of *Cato*. He was the first man on the boards till Garrick made his appearance, of whom Quin at first spoke rather contemptuously. He continued a favourite performer until the year 1748, when, on some dispute between him and Rich the manager, he retired to Bath, and only came up annually to act for the benefit of his friend Ryan, until the loss of two front teeth spoiled his utterance for the stage. Whilst Quin continued upon the stage, he constantly kept company with the greatest geniuses of the age. He was well known to Pope and Swift; and the Earl of Chesterfield frequently invited him to his table; but there was none for whom he entertained a higher esteem than for the poet Thomson, the author of the *Seasons*, to whom he made himself known by an act of generosity that does the greatest honour to his character. Quin's splendid elocution recommended him to Frederick, Prince of Wales, who appointed him to instruct his children in speaking and reading with a graceful propriety; and Quin being informed of the elegant manner in which his majesty delivered his first speech from the throne, he cried out in a kind of ecstasy, "Ay, I taught the boy to speak." Nor did his majesty forget his old tutor; for, soon after his accession to the throne, he gave orders, without any application being made to him, that a pension should be paid to Mr Quin during his life. Quin, indeed, was not in absolute need of this royal benefaction; for, as he was never married, and had none but distant relations, he sunk L.2000, which was half his fortune, in an annuity, for which he obtained L.200 a year, and, with about L.2000 more in the funds, lived in a decent manner during the latter part of his life at Bath, whence he carried on a regular correspondence with Garrick, and generally paid a visit to his friends in the metropolis once a year, when he constantly passed a week or two at the great actor's villa at Hampton. He died of a fever in 1766.

QUINARIUS was a small Roman coin, equal to half the denarius, and consequently worth about threepence three farthings of our money. It was called *quinarius*, because equal in value to five asses, just as the denarius was named from its containing ten.

QUINAULT, Philippe, a French lyric poet of some note, was born at Paris in 1635. He pursued the study of law for some time, but preferring the poetry of the stage, he afterwards renounced his legal profession in favour of the drama. His tragedies and comedies, written for the Théâtre Français, are now forgotten. In 1673 he commenced writing for the Grand Opera, and his lyrical talent gained for him entire success. He is regarded as the best operatic writer which France has yet produced; and A. W. Schlegel even prefers his light, animated, fantastic style to that of the great Italian Metastasio. *Armide* is considered his masterpiece. He received the order of St Michael at the hands of Louis XIV., with a pension of 2000 livres (L.100); and was a member of the French Academy, and of the Academy of Inscriptions and Belles-Lettres. Quinault ceased to write when Lulli, who set his pieces to music, died. The poet outlived the musician only a year; and leaving his daughters a considerable fortune, he died in 1688. His dramas have been collected and published, under the title of *Le Théâtre de M. Quinault, contenant ses Tragédies, Comédies, et Opéra, Edition augmentée de sa Vie, et d'une dissertation sur ses Ouvrages et sur l'Origine de l'Opéra*, 5 vols. 12mo, Paris, 1715.

QUINCUNX, in gardening, is a plantation of trees, disposed originally in a square consisting of five trees, one at each corner, and a fifth in the middle; or it is applied to trees planted in oblique lines of three and two.

QUINCY, a town of Massachusetts, in the United States of North America, near the shore of a bay of the same name in Boston harbour, 8 miles S. by E. of Boston. It is well built on level ground, and has a stone church, a handsome granite town-house, a newspaper office, and two banks. It is chiefly remarkable for its granite quarries, in which about 1000 workmen are employed, and from which granite is sent to various parts of the country. Pop. (1850) 5017.

Quincy, a town of the United States of North America, capital of Adams county, in the state of Illinois, stands on a limestone cliff on the left bank of the Mississippi, in the midst of a rich undulating prairie-land, 170 miles above St Louis, and 104 W. of Springfield. It has a large public square, numerous churches, a handsome court-house, several newspaper offices, and three banks. There are numerous manufactories, including distilleries, machine shops, foundries, flour and saw mills worked by steam, &c. An active trade is carried on by steamers on the Mississippi. Pop. (1850) 6901; (1853) 11,000.

QUINDECAGON, a plain figure with fifteen sides and fifteen angles.

QUINDECIMVIRI. See Decemviri.

QUININE, or Quinia, a vegetable alkaloid discovered by modern chemistry in the yellow Peruvian bark (*Cinchona cordifolia*). It is a white powdery substance, sparingly soluble in water, but dissolved by warm alcohol, from which it is not deposited in crystals. Quinine unites with acids, and forms salts, the most important of which is the sulphate. It is soluble in water, and crystallizes. In the dose of one grain twice or thrice a day it is the most valuable of all the vegetable tonics, and in larger doses it is the best of all the antiperiodics. Quinine should not be administered where there is a tendency of blood to the head.

QUINQUATRUS, or Quinquatria, was a festival celebrated at Rome in honour of Minerva, and which was celebrated on the 19th of March, and lasted five days. On the first day they offered sacrifices and oblations without the effusion of blood, and was considered the festival proper; the second, third, and fourth were spent in shows of gladiators; and on the fifth day they went in procession through the city. Scholars had a vacation during the solemnity, and at this time presented their masters with a gift or fee, called *Minerval*. Boys and girls used to pray to the goddess Minerva for wisdom and learning, of which she had the patronage. Plays were acted and disputations held at this feast on subjects of polite literature. The quinquatrus was so called because, according to Varro, it was held the fifth day after the Ides.

QUINQUEREMIS, in the naval architecture of the ancients, is a name given to a galley which had five benches of oars. The invention of them is ascribed to the reign of Dionysius. They in general divided their vessels into *monocrota* and *polycrota*. The former had only one tier of rowers; the latter had several tiers of them, from two or three up to twenty, thirty, or even forty; for in the time of Philopater we have an account of such a vessel, which required no less than four thousand men to row it.

QUINQUIVIRI, in Roman antiquity, were five extraordinary magistrates frequently appointed to carry any measure into execution.

QUINTANA, Manuel Josef, an eminent Spanish poet and patriot, frequently called "the Spanish Tyrtæus," was born at Madrid in 1772. He was educated at Salamanca, and adopted the profession of the law under the patronage of Jovellanos. But he secretly indulged a preference for letters; and in 1801 he wrote his tragedy of *The Duke of Viseo*, and in 1805 he produced his *Pelayo*. The former had but little success; but the latter, which had been designed to rouse his countrymen to a resistance of foreign oppression, struck a chord in their hearts which it took a number of years to allay. Meanwhile, in 1802, he had published a thin volume of poems almost entirely lyrical, which rang through the hearts of the half of Spain. He wrote in the same spirit, in 1807, a volume containing the lives of five distinguished Spaniards who had successfully fought the enemies of their country. He at the same time prepared three volumes of selections from the best Spanish poets, accompanying them with critical notices, which were not without occasional Gallicisms, but yet were thoroughly national in spirit, and were unquestionably superior to anything of the kind in the Spanish language. Many years afterwards Quintana added both to the lives and selections. At the outbreak of the revolution of 1808 Quintana devoted all his talents and all his fortune to the service of his country. He wrote *Odes to Emancipated Spain;* he harangued his countrymen through the journals; he penned the proclamations, manifestoes, and addresses which so honourably distinguish his career as secretary to the Cortes and to the regency; and he had his reward. Ferdinand VII. no sooner gained his freedom from France than, in 1816, on his return to Madrid, a persecution was instituted against the very men who had contributed to his liberation. Quintana was imprisoned in the fortress of Pamplona for six miserable years, without even the use of writing materials. But a change came at last. In 1820 he was raised to greater distinction than he had known before, which he was allowed to enjoy for three years, when another political revolution took from him both place and power. He retired to Estremadura till the king's death, when he was again restored to his old public offices, was created a peer of the realm, and received a crown of laurel from the hands of the present Queen of Spain, whose education he had superintended. He died at Madrid on the 11th March 1857, aged eighty-four. His funeral was attended by the leading nobility and all the noted men of letters in the Spanish capital.

Quintana's complete works will be found occupying a volume of the *Biblioteca de Autores Españoles* of Rivadeneyra, by Ferrer del Rio, published in 1852. His *Lives of Celebrated Spaniards* has been translated into English by Preston.

QUINTANAR DE LA ORDEN, a town of Spain, in the province of Toledo, 63 miles S.E. of Madrid. It has two large squares, a good town-hall, church, prison, schools, hermitages, &c. Oil, flour, chocolate, soap, bricks, tiles, blankets, ropes, and other articles, are made here; and large markets are held. Pop. 5656.

QUINTETTO (English, *Quintet*), in music, a composition for five voices, or for five instruments, each of which is *obligato*. The remarks that have been made upon the construction of the quartetto apply generally to that of the quintetto. Amongst the finest instrumental quintettos are those of Boccherini, Mozart, Beethoven, and Onslow. The best that have been composed for wind instruments only are A. Reicha's, for flute, oboe, clarinet, horn, and bassoon. (G. F. G.)

QUINTILIANUS, M. FABIUS, a celebrated Roman rhetorician, chiefly eminent for his treatise on oratory. The main facts of his life, as far as they are known to us, are derived from his own allusions in this celebrated work. His father seems to have been a man of some note (ix. 3, § 73), and from a passage in Seneca, it has been inferred that he was a declaimer. If so, Seneca speaks of him very slightingly (*Controv.* v., pref., p. 318), as a man whose oratorical reputation had not survived him. Others suppose that the Quintilian noticed by Seneca was the grandfather of M. Fabius; but the name was so common that any assumption about it is highly precarious.

Quintilian is said to have been born at Calagurris in Spain (Auson. *Profess.* i. 7; Euseb. *Chron.* ad. Ol. ccxi.), and we hear of other Quintilians in that country at a much later period (Prudent. *Hymn.* vii. 152). Doubt has been thrown on this fact from the silence of Martial, who being himself a Spaniard, would naturally have been glad to have included a man whom he so profoundly admired (*Ep.* ii. 90) in the list of his distinguished fellow-countrymen. Some weight must undoubtedly be attached to this argument, and his birthplace be regarded as uncertain. He was certainly educated at Rome, and repeatedly alludes to the instruction he received from Domitius Afer, whose waning powers were the more conspicuous from his unwillingness to abandon an arena in which he had excelled all his contemporaries, although they were men of such high reputation as Julianus Africanus and Servilius Nonianus (v. 7, 7; x. 1, 24, 118, &c.) Quintilian was then a mere youth (*adolescentulus*) during the old age of this distinguished orator; and he must therefore have been born A.D. 40–42, for Domitius Afer died in the reign of Nero, A.D. 60. When his education was completed, and after the death of his friend and instructor, he went to Spain with Galba, and stayed with him during his eight years' administration of Hispania Tarraconensis. At the end of this period he returned to Rome with his patron, and began to practise at the bar with such distinction that his name became with his contemporaries a proverbial term for a consummate orator. (Juv. vii. 280.) He won still greater distinction in the office of a teacher (*moderator summe juventæ*, Mart. ii. 90), and had the good fortune to number Pliny among his pupils. (Plin. *Ep.* ii. 14, § 9; vi. 6, §§ 3, 32.) We cannot wonder at his brilliant success, if his practice in any way came up to the noble requirements of his theory. His general remarks on education, distinguished as they are by the calmest good sense, may still be read with advantage; and the arguments by which he maintains the superiority of a public to a private education, give an irresistible answer to the objections which eighteen centuries have not sufficed to clear away. Probably few men came nearer to his marvellous ideal of a tutor than he did himself, as we may conjecture from the affectionate respect which he received from his pupils, and from the use of his name by Juvenal as a general expression for a pure and honourable man. (*Sat.* vi. 75.) When we add to this the certainty that he fully gained *during his lifetime* the reputation which he had justly earned, his biography presents a picture of rare good fortune. Two emperors singled him out for their most conspicuous marks of approbation. Domitian entrusted to him the education of his sister's grandsons (*Inst. Orat.* iv. preæm.); and Clemens, the father of these youths, obtained for him, in gratitude for his instruction, the honours and empty title of consul (Anson. *Grat. Act.* ante med.) Although this office had long been shorn of all its political power, it may well have seemed a guerdon sufficiently splendid to excite the envy of contemporaries as a freak of fortune. (Juv. vii. 194.) From Vespasian he received the still more substantial recognition of a regular salary of 100,000 sesterces (between L.800 and L.900) a year out of the privy purse, with the additional honour of being the first recipient of a bounty which was afterwards continued in imitation of this excellent precedent. (Suet. *Vesp.* 18.) These distinctions were showered upon him at the close of his public duties, when, after twenty years of professional labour, he was employing his retirement in the composition of his great work, the *Institutiones Oratoriæ*.

But in spite of his brilliant success, the life of Quintilian was embittered by the severest domestic misfortunes. He had married, probably late in life, a very young girl, who, after bearing him two sons, died before her twentieth year. He speaks of her with almost parental tenderness, and says that his sons were his only consolation. Of these, the younger, a child of the utmost promise, died a few months after his mother, while the father was diverting his thoughts with the composition of his treatise *De Causis Corruptæ Eloquentiæ*. All his hopes were then centred in the young Quintilianus, whose unusual abilities formed a strong stimulus to his father's diligence, and heightened his desire to complete, before his own death, his larger and more celebrated work. But these hopes were destined to be blighted; the boy died, after eight months' illness, in the tenth year of his age, and Quintilian bitterly complains that the fruit of his labours was destined to be reaped by any one rather than those for whose sake he had so fondly written. Besides showing him in a very amiable domestic character, the autobiographical digression, in which he informs us about these circumstances, is valuable, as illustrating Quintilian's high position; for the son whose loss he so pathetically laments had been adopted by a man of consular dignity, and already betrothed to the daughter of a prætor. (*Inst. Or.* vi. Proæm.)

Pliny wrote one of his extant letters to a Quintilian, whom he addresses in affectionate terms, and to whom he sends a present of 50,000 sesterces (between L.400 and L.500), as a present for his daughter on her marriage to Nonius Celer, a Roman knight. He apologises for so trifling a present (*munusculum*) by saying that he would not have succeeded in persuading him to accept a larger sum, and adds that his friend's means were disproportionate to the wealth of his intellect. (*Ep.* vi. 32.) If the Quintilian here addressed be the author of the *Institutiones* (as appears most probable), he must have married the daughter of Tutilius when he was at least fifty, and have lived to a considerable age. We see no improbability in this, since the death of his children, and the very short duration of his previous married life, would naturally induce him to a second marriage. The date of his death is entirely uncertain.

Doubt has been thrown on the identity of the great Quintilian with the one mentioned by Pliny, because in this epistle he is said to have been "modicum facultatibus," whereas we have seen that he enjoyed a handsome pension; and Juvenal quotes him as an instance of a literary man who possessed the amplest means. We may add to this that he himself alludes to his circumstances ("facultates patrimonii nostri") in terms which show that he had a considerable competence. There is, however, no real difficulty here. The general tone of Pliny's letter shows that he was addressing a rich man, though one poorer than himself; and there is an obviously sarcastic exaggeration in the jealous language of Juvenal, who, although he felt for Quintilian a sincere respect, probably disliked him as a court favourite under a detestable tyrant. It has been well remarked that Quintilian was "a rich man among the poor, and a poor man among the rich."

He lived in times which were perilous to the honesty of prominent and able men. Comparatively few of his contemporaries escaped without a stain from the all but universal corruption of that dark period, when, as Niebuhr expresses it, "the world was effete with the drunkenness of crime." Many of the eminent men with whom Quintilian lived on terms of intimacy, and among them Domitius Afer, were "prosperiore eloquentiæ quam morum famâ." (Tacit. *Ann.* iv. 5.) It is even strange that in close proximity to men so distinguished for genius, yet so degraded by moral weakness, Quintilian should still have maintained his celebrated theory, that a splendid eloquence is incompatible with an immoral life. (*Inst. Or.* i. 2.) And yet there is not a single reproach against Quintilian's own character, unless it be the adulation with which he addresses the Emperor Domitian on being requested to undertake the education of his grand-nephews. Considering the high compliment which was involved in his selection for this office, and the general prevalence of flattery far grosser and more extravagant (Vell. Paterc. ii. 94, 104; Stat. *Sylv.* i. 1, 62; Mart. v. 81), we cannot but consider this a venial offence. Quintilian was no politician, and even if he had been, such insane compliment is too preposterous to do any harm. We might call it a vice rather of the period than of the individual, did we not know historically how seductive are the blandishments of royalty. Even Lord Chatham, a far greater man than Quintilian, burst into tears on receiving from George III. a few words of ordinary civility.

Quintilian's chief claim to the respect of posterity rests on his famous work, *Institutiones Oratoriæ*, written mainly with a view to the education of his own son and the son of the courtly orator Marcellus Victorius, to whom he dedicated it. The publication of it was hastened by the generally expressed wish, that he would embody in writing the results of his long experience, and by the fact, that no less than two unauthorized editions of his rhetorical notes, full of imperfections, had already been brought before the world by the ill-judged zeal and admiration of his youthful auditors. He tells us that he composed the present work in rather more than two years, amid the interruption of numerous other engagements; but it gives the result of many years' study of the subject, and contains all that he considered most valuable in numerous earlier treatises, both Greek and Latin. It forms a complete compendium of every topic likely to be technically useful in the education of a young aspirant to the honours of eloquence. It is the clearest and most practical of rhetorical manuals; and though inferior to Cicero's *De Oratore* in a literary point of view, is much more adapted to be practically useful. Quintilian's style is graceful, lucid, and flowing; and although he was not so pedantic as to avoid every expression which wanted the classic stamp of the Augustan period, yet he may be regarded as the restorer of good taste, and "can in no way be classed among the writers of the *Argentea ætas.*" (Niebuhr.) The first MS. of Quintilian was discovered by the Florentine Poggio in the tower of the monastery of St Gall, when he was attending the council of Constance. The first printed edition was that of Campanus at Rome in 1470. The best commentary is that of Spalding (completed by Zumpt and Bonnelli), who gives in his Preface an imperfect and desultory sketch of Quintilian's life.

It is now generally agreed that the work *De Causis Corruptæ Eloquentiæ* is lost. It was long identified with the *Dialogus de Oratoribus*, which is more rightly assigned to Tacitus, and usually printed by modern editors among his works. The arguments about the authorship are well and briefly given by Spalding in his note on *Institutiones Oratoriæ*, vi. preæm., and need not be recapitulated here. The one hundred and sixty-four declamations which long passed under the name of *Quintilian*, are universally acknowledged not to be his. They are the feeble and tasteless productions of those rhetorical schools which, by encouraging empty rant on subjects which had the least possible affinity with real human interests, tended radically to vitiate the taste of young orators. Tacitus and Petronius Arbiter alike condemn the futile and fantastic manner of these discussions, which degraded eloquence into affectation, and made it the orator's sole object to surprise by unexpected and unusual expressions, and emasculate his sentences by a nauseous superfetation of quips and flourishes. The ridiculous and intolerable style of the later Roman writers, with the archaisms and euphuisms with which they elaborately endeavour to conceal their barrenness of thought, was the natural development of so mistaken a practice. (F. W. F.)

QUINTUS SMYRNÆUS, called QUINTUS CALABER, a Greek poet, who appears to have lived about the end of the fourth century A.D., and who wrote a supplement to Homer's *Iliad*, in fourteen books. The poem was discovered by Cardinal Bessarion, and was first published by Aldus in 1504 or 1505. The best edition is that of Tychsen, Strasburg, 1807.

QUIRITES. See ROME.

QUITO, the capital of the republic and of the department of Ecuador, stands in a ravine on the E. side of the volcano Pichincha, 9534 feet above the sea, 150 miles N.N.E. of Guayaquil; S. Lat. 0. 13., W. Long. 78. 50. A small part of the town is built on level ground, but the most of it occupies the slope of a hill, which is in some places exceedingly steep. The level part is chiefly occupied by a large square, containing the cathedral, episcopal palace, government palace, and town-hall, and having a fountain in the centre. From the corners of this square extend four broad, straight, but short streets, which are the best in the town; the others being narrow, crooked, and uneven, and many of them unpaved. The cathedral is a plain building, and is excelled in beauty by some of the other churches. The former Jesuits' college, a large and handsome building, with a Corinthian front, is now occupied by the university. There are also two ecclesiastical colleges, and several convents and hospitals. The houses are seldom more than one storey in height, and are generally built of sun-dried bricks, flat-roofed, and thatched with *maguey* leaves. Cotton, coarse woollen fabrics, hosiery, silk, lace, leather, and confectionary, are among the manufactures of the town. The markets are well supplied with provisions; grain and other rural produce are exported to central America, and hardware, cloth, &c., imported from Europe. Quito was founded by Sebastian Benalcasar in 1534. It has frequently suffered from earthquakes. Pop. 70,000.

QUORUM, so called from the words of the commission, *quorum A. B. unum esse volumus* ("of whom we will that A. B. be one"); thus rendering it necessary that certain individuals (said to be of the *quorum*) should be present at the transaction of business.

R.

R, a liquid consonant, being the eighteenth letter of the English alphabet. Its sound is formed by a guttural extrusion of breath vibrated through the mouth, with a sort of quivering motion of the tongue drawn back from the teeth, and advanced with the tip a little elevated towards the palate. It is convertible with the letters *l*, *n*, *m*, and *s*. It is apt to place itself at one time before, at another time after a vowel, and is liable to disappear from the neighbourhood of several consonants.

In the notes of the ancients, R. or RO. signifies *Roma*. R. C. *Romana civitas*; R. G. C. *rei gerendæ causa*; R. F. E. D. *recte factum et dictum*; R. G. F. *regis filius*; R. P. *res publica*, or *Romani principes*, and R. R. R. F. F. F. *res Romana ruet ferro, fame, flamma*. (See ABBREVIATIONS.) Used as a numeral, R anciently stood for 80; and with a dash over it, thus $\bar{\text{R}}$, for 80,000; but the Greek R, $\acute{\rho}$, with a small mark over it, signified 100; with the same mark under it, it denoted 1000 × 10; thus ρ͵ signifies 100,000. In the Hebrew numeration ר denoted 200; and with two horizontal points over it, thus ר̈, 1000 × 200; = 200,000. In the prescriptions of physicians, R or ℞ stands for *recipe*, that is, "take."

RAAB (Magyar *Györ*), a town of Hungary, capital of a county of the same name, in the midst of a wide marshy plain at the confluence of the Raab, with the Little or Wieselburg Danube, 34 miles S.E. of Pressburg, and 67 W.N.W. of Buda. Besides the town properly so called, which is defended by a castle, and surrounded by fortifications and a glacis, there are extensive suburbs. It is well built, chiefly of stone, and some of the streets are straight and regular. Among the chief buildings are the old and splendid cathedral; several other Roman Catholic, a Protestant, and a Greek church; Benedictine and Ursuline convents. The educational establishments include an archigymnasium, a royal academy with legal and philosophical faculties and a library, an Episcopal seminary, and other schools. There are also an orphan hospital, theatre, barracks, and arsenal. Large horse markets are held here; and there is a considerable trade in corn. The only manufacture of any importance is that of tobacco, which is carried on by the government. Raab is connected by railway with Vienna and with Buda; and steamers ply between it and Gönyö, on the Danube. A battle was fought under the walls in 1809, in which Napoleon totally defeated the disorderly force of the Hungarian nobles. Pop. (exclusive of the military) 16,000.

RAAT, a town of British India, presidency of Bengal, capital of a pergunnah of the same name in the district of Humeerpore, 46 miles S. of Calpee. It is a populous and thriving town, having a bazaar, and being well supplied with provisions and water. It is, however, very unhealthy, on account of the swamps and rank vegetation of the adjacent country. Pop. 8616.

RABATT, a seaport of Morocco, on the S.W. side of the Bu-Regreb, at its mouth in the Atlantic, in the province and 100 miles W. of Fez. From the bank of the broad, full river rise groups of palms and minarets, mosques and mausoleums, the time-worn walls of the town, the battlements of the citadel, and the lofty tower of Sma Hasann, on a cliff to the S.E., forming a conspicuous sea-mark for many miles off. There are pretty good fortifications towards the sea, consisting of a wall flanked by round batteries; and the entrance of the river is commanded by another battery with 24 guns. The citadel is also mounted with artillery. Many of the houses are large, but the streets are narrow and dirty. The mouth of the river is obstructed by a bar of shifting sand; and in winter the surf is frequently so violent as to make the entrance very dangerous. Vessels entering can moor close to the town, where there is room for about twelve; but they are sometimes compelled by stress of weather to go farther up the river. The manufactures of Rabatt are considerable, including carpets, mats, rugs, serge, woollen and cotton cloth, ropes, hemp, heather, saddles, bridles, muskets, &c. Salt is made both here and at Sallee, on the opposite side of the river, with which communication is kept up by boats. The trade of the town is considerable: calico, cotton, linen, muslin, hardware, cutlery, tinplate, sugar, tea, &c., being imported; and wool, wax, oil, hides, bark, pease, beans, gum, and other articles exported. The quantity of exports and imports would in all likelihood be much greater than it is, were it not for the high duties and government monopolies. Pop. about 35,000, of whom 28,000 are Mohammedans and 7000 Jews.

RABBI (Ῥαββί), a title of honour given to the teachers of the law in the time of Christ, and for which there is no exact equivalent in our language, though perhaps in purport and usage it comes near to "doctor" or "master:" a word combining *both* these significations would fairly represent it. The actual signification of רב (*rab*), in Hebrew is "a great one,"—*i.e.*, a chief, a master; and would as a title be probably represented by the "Excellenza" of Southern Europe, which is perhaps as common as Rabbi was among the Jews. It was there employed as a title in the Jewish schools in a threefold form, indicating as many degrees, which might without much impropriety be compared, in the stricter sense, to the progressive academical degrees of Bachelor, Master, and Doctor. The lowest of these degrees of honour was רב (*rab*). This, with the relative suffix, became רבי, Ῥαββί, *Rabbi*, "my master," which was of higher dignity; and beyond that was רבן (*Raban*), "great master;" or with the suffix רבני (*Rabboni*), "my great master," which was the highest of all. It is not certain, however, that this graduation of terms existed in the time of Christ. The teachers and professors of the law were distinguished by the title of Rabbi both by the people and by their own disciples.

RABBIT. See MAMMALIA.

RABELAIS, DR FRANÇOIS, immortalized by his romance of *Gargantua and Pantagruel*, was born at Chinon, a little town of Touraine, in 1483. His father, Thomas Rabelais, is generally understood to have been an apothecary of that town, and proprietor of the farm of La Devinière in the neighbourhood, celebrated for an excellent Burgundy which was grown upon it, and where, it is said, a great part of the romance was written. According to some biographers, however, he was a vintner in Chinon, and kept a cabaret there at the sign of the Lamprey. The probability is, that, in a certain sense, he combined both occupations, dealing in drugs and spices, "and other things of great price;" and also, like many other gentlemen of good position, disposing of the wine produced upon his own property, a traffic very different in its nature from that suggested by the modern ideas of an apothecary and keeper of a cabaret. He was unquestionably a man of substance, and able to procure for his son an education of as high a character as was then to be obtained. He sent him to be educated by the monks of Seuilly, an abbey not far from Chinon; but the boy's progress under their care was so unpromising as to occasion his removal to the university of Angers, according to some biographers, or according to others, to the convent of La Baumette, near that town. Here he studied for some time, but apparently with no more satisfactory results than before. It was at this establishment that he made the acquaintance of the brothers Du Bellay, one of them afterwards the celebrated cardinal. The friendship then formed lasted through life, and ultimately proved of the greatest service to Rabelais. It may be assumed that it was rather from submission to his father's wish than from natural inclination that he is found to have soon afterwards adopted a monastic life. In 1511, after passing through the usual preparatory studies, he was admitted into the order of Cordeliers at the convent of Fontenay-le-Compte in Poitou, where he assumed the religious habit. Here he prosecuted his studies with such zeal as to retrieve any loss of time which indifference or injudicious tutors might previously have occasioned. Striking out of the usual routine of scholastic study, which then held undivided sway in the monastic houses, he applied himself with unusual industry and research to the cultivation of the sciences. It was his aim, says Niceron, to become a grammarian, poet, philosopher, physician, jurist, and astronomer; and the encyclopædic knowledge displayed in his works bears ample testimony to his success. He possessed a peculiar aptitude for the acquisition of the languages; an aptitude which afterwards showed itself in his command of Italian, Spanish, German, English, Hebrew, and Arabic. At this period, in fact, he was a perfect master of the Latin and Greek tongues, the latter of which had for some time been engaging the attention of the most enlightened spirits of the age. Within the walls of Fontenay-le-Compte, however, a Greek book was looked upon as no better than a work of magic, and the man who commanded the key to its secrets passed for a trafficker in "the arts inhibited;" and Rabelais' attachment to the Greek writers drew upon him and his friend Pierre Ami, a brother of the same order, the hatred and persecution of his fellow-monks. His independence of spirit and generous ardour in the pursuit of learning, which could not but be felt as a reproach to their own resolute ignorance, pedantry, and sloth, were continually furnishing fresh incentives to their rancour, and they omitted no opportunity of subjecting his friend and himself to annoyance. Among other persecutions to which they were subjected, their cells were ransacked, and their precious Greek volumes confiscated. Worn out by repeated aggressions, Rabelais followed the advice of his friends, and resolved to quit a society where he found so little that was congenial to his own disposition. It has been alleged that the true cause of this step was his own profligacy; but this is only the first of the many groundless charges against him, engendered either by the malice of his enemies, or originating in a misapprehension of his character from the nature of his famous romance, as that of a man whose whole life was a noisy jest, a soulless round of sensual indulgences. Had such really been his character, as has been pertinently remarked by Père Niceron, "these were not the days when, for such a cause, he needed to have left his monastery; he might have given free rein to his propensities there, and yet have made no deviation from the ordinary course." The authority of a churchman on such a point is conclusive. But there is direct evidence, in the letters of Budæus, that Rabelais was persecuted because of his much-dreaded knowledge of the noblest language of antiquity. "Multa et atrocia passus gratia amoris Græcarum literarum," are the words of Budæus.

Rabelais had by this time made influential friends, who, seeing how uncongenial to his nature were all the habits of the severe order of Mendicant friars to which he belonged, exerted themselves to secure for him the advantages of a milder order. Accordingly, about the year 1524 a brief was obtained from Pope Clement VII., allowing him to pass from the order of St Francis into that of St Benedict; and leaving this "pack of capuchins, monks, who forbade the use of beans, that is, Pantagrueline books," to borrow a phrase from the prologue to the fifth book of his romance, he entered the monastery of Maillezais in Poitou. There he remained during several years; but he appears to have found himself little better off in his new quarters than in those which he had left. They did not present him, it is said, with such resources as he desired for extending the limits of his knowledge, more especially in medical science. He accordingly quitted the monastery abruptly. His motives for this step were doubtless of a mingled nature, of which it is but reasonable to suppose the chief was a disgust at the torpor and profitless seclusion of a monastic life, by escaping from which he could alone hope to find opportunities for exercising his stirring and strongly practical intellect in a field of action, observation, and experience, sufficiently ample for its desires. However this may be, he laid down the regular habit for that of a secular priest, and quitted Maillezais without the sanction of his superior, a breach of ecclesiastical discipline which exposed him to its severest censures. After rambling about for some time in the diligent pursuit of medical knowledge (as he says himself in his petition to Pope Paul III. for absolution from the penalties incurred by his unauthorized retirement from Maillezais), he settled at Montpelier in 1530, and, after taking his physician's degree at its university, practised the medical profession there with credit and success. It appears by the dedication to Godefroy d'Estissac, then bishop of Maillezais, who had studied along with him at La Baumette, of an edition of Hippocrates' *Aphorisms* and the *Ars Parva* of Galen, published by Rabelais in 1532 at Lyons, and highly esteemed by the medical and literary men of the time, that his lectures on physic at the university of that place had attracted considerable attention. Such, indeed, was the distinction he attained, that he was selected by the university as their deputy to procure a restitution of the privileges of which one of its colleges had been denuded by the chancellor Du Prat. The means employed by Rabelais for obtaining access to the chancellor have formed the subject of a story to be found in all his biographies; but it is too obviously a fabrication from an incident in his own romance (the introduction of Panurge to Pantagruel, book ii., c. ix.) to deserve a place here. He succeeded in the object of his mission, and his services to the university were perpetuated in a custom, still, according to the *Biographie Universelle*, in existence, by which every candidate is required to put on Rabelais' gown upon receiving his physician's degree.

In 1532 we find him established at Lyons, where he was hospital physician, and taught and practised for several years. During his residence in Lyons, Rabelais published several works. Besides those above mentioned, he published in 1532 the *Epistolæ Medicinales Manardi*, and edited numerous publications on medicine, archæology, and jurisprudence. He edited a series of almanacs from 1533 to 1550, which are chiefly interesting for their disclaimers of that power of divination to which the professors of astrological science have always pretended. "Ce sont les secrets du conseil étroit du Roi éternal," he says, in the almanac for 1533, speaking of future events, "que tout ce qui est et ce qui fait modère à son franc arbitre et bon plaisir, lesquels vault mieux taire et adorer en silence." It is probable that he acted as corrector of the press for one of the great printing establishments, from which at this period emanated many of the most celebrated editions of both the Italian and French authors. At the commencement of the year 1534 his old schoolfellow and friend, Jean du Bellay, then bishop of Paris, having occasion to pass through Lyons on his way to the papal court, regarding the divorce of Henry VIII. of England, took Rabelais along with him in the capacity of his physician; thus enabling him to realize what had long been his passionate wish, a personal acquaintance with Italy and the Eternal City. For, to use the words of his dedication to Du Bellay of an edition of Marliani's *Typographia Antiquæ Romæ*, published, under Rabelais' superintendence, by Gryphius at Lyons in 1534, "from the first moment that I was able to appreciate the worth of polite learning, it was amongst the foremost of my desires to travel throughout Italy, and to view the capital of the Roman world." The opportunity for gratifying the popular conceptions of his character afforded by this visit of the great satirist of the abuses of the Romish Church to the court of its supreme head, has not been overlooked by the anecdote-mongers; and several absurd stories of his conduct have accordingly been handed down from biographer to biographer, till they seem almost to have acquired the authority of undoubted truths. One specimen of these will be sufficient. When the Cardinal du Bellay was presented to the Pope, he, as ambassador of Francis I., went through the usual ceremony of kissing his holiness's slipper. His suite followed his example, all except Rabelais, who remained leaning against a pillar, and exclaimed, loud enough to be heard, "that if his master, who was a great lord in France, were unworthy to kiss the Pope's feet, his holiness might untruss, and possibly, after reasonable abstersion, a part might be found where an humble follower like himself might presume to apply his lips." The improbability that Rabelais should have expressed himself in these terms, filling the situation which he did, and when, too, he was on the eve of supplicating a release from this very Pope from the ecclesiastical penalties he had incurred by his unauthorized desertion of the monastery of Maillezais, speaks sufficiently for the worthlessness of this story. But its real source is obvious enough, and may be found in book iv., c. xlviii., of his romance. It needed but a poor invention to construct such a tale out of the extravagant devotion of the worthies who greeted Pantagruel and his band on their arrival at the island of Papimany. That, however, which, as told by Rabelais himself, is a stroke of the most caustic satire, makes but a sorry jest in the hands of those who first invented a theory of his character, and then fabricated anecdotes to support and illustrate it. Rabelais' judgment, it is certain, was quite as powerful as his wit; and he knew too well when to discharge his bolt with effect ever to let it fly where detriment to the archer himself could alone be the result. The veil of extravagance which he has thrown over his great satirical work, is the best possible proof how unlikely he was to be guilty of any such piece of superfluous imprudence.

Rabelais seems to have gone back to Lyons for a time, as his Epistle Dedicatory to Du Bellay of his edition of Marliani's *Antiquitates Romæ Antiquæ* is dated from that city on the 31st of August 1534. He returned shortly afterwards to Rome, and rejoined Du Bellay, who had been created cardinal on the 21st of May 1535. His letters to Godefroy d'Estissac, whose favour he had won during his residence at his abbey of Maillezais, and continued ever afterwards to retain, are dated from Rome during the two following years. Availing himself of the opportunity which his presence on the spot afforded, he petitioned Pope Paul III. to be absolved from the penalties incurred by the abandonment of his order. Rabelais' merits had secured him the esteem of Cardinals de Genutiis and Simonetta, and they combined with Du Bellay and the Bishop of Mascon in forwarding his petition. By their exertions a bull in his favour was obtained gratis, contrary to the usual practice. It was granted on the 17th of January 1536, in terms of his request, allowing him to return into any house of the Benedictine order which would receive him, and to practise physic, upon condition of his doing so without hope of fee or reward. This release from the ecclesiastical disabilities consequent upon his transgression of the church's rules, enabled the Cardinal du Bellay to assign him a place in his abbey of St Maur des Fossez, near Paris. Here he remained until the year 1542, when he was appointed by the same friend to the cure of Meudon; and he continued in the zealous discharge of the duties of this station down to the close of 1551. "Ever mindful," says Niceron, "to instruct his people, he made it part of his care to give their children a knowledge of church music, of which he was himself a thorough master. His house was always open to the poor and wretched, whom he assisted to the utmost of his means; and he was in the habit of drawing men of learning and science about him, to discourse with them upon their several pursuits. Against women, however, his gates were barred, and his reputation on this score is wholly without blemish. This," he adds, "is the uniform testimony of contemporary biographers; and Antony Le Roi, who wrote a Life of him in 1649, avers that such was then the prevailing tradition at Meudon. His knowledge of medicine rendered him doubly useful to his parishioners, who invariably found him ready to minister to their wants both corporeal and spiritual." He died in Paris in 1533, in the Rue des Jardins, parish of St Paul, and was buried in the cemetery of that church.

His death-bed has not escaped profanation by the caterers for the jest-books; and there are few stories more common than his calling for his domino when he felt his end approaching, with the words, "Beati qui in Domino moriuntur." Another anecdote, even more detrimental to his character, is in every-day circulation, by which he is reported to have replied to a page sent by Du Bellay to inquire after his health, "Tell your master the state you find me in; I am going in quest of a Great Perhaps. He is up in the jay's nest. Bid him keep where he is; and for you, you will never be anything but a fool. Draw the curtain; the farce is ended." Those who have read Rabelais' spirit aright need no confutation of this slanderous fabrication of monkish malice, the miserable patchwork from some half-dozen threadbare facetiæ. The simple fact recorded by Du Verdier is worth a thousand such tales; and it determines, if indeed such evidence were necessary, Rabelais' opinion as to the momentous doctrine which he is here represented to have viewed as no more than "a great perhaps." In a copy of Galen, annotated throughout in the handwriting of Rabelais, which had come into the Bishop of Evreux's possession, opposite a passage in which Galen argues for the mortality of the soul, Rabelais had written, "Hic vero Galenus se plumbeum ostendit." Du Verdier also states, whilst at the same time he retracts what he had formerly been led, in accordance with the popular voice, to say against Rabelais in his *Bibliothèque Française*, that "the manner of his death compels us to form a judgment of him totally at variance with that which is currently received." The particular circumstances of this event are not now known, but they were doubtless such as became a pious and eminently thoughtful man.

One cannot help regretting, with Coleridge, "that no friend of Rabelais, and surely friend he must have had, has left an account of him." Had any such account existed, it would unquestionably have conveyed an impression of his personal character very different from that which the current anecdotes of him are calculated to produce. It is the peculiar misfortune of distinguished humourists to have the paternity of such jests as are tossing unclaimed about the world laid to their charge. They become a sort of foundling hospital for wit; and Rabelais has had more than his share of this abandoned progeny thrust upon him. His reputation as a man has suffered accordingly, and this for an obvious reason; for just in the degree that a great man's mind is marked by features which puzzle the finest sagacity to discriminate and reconcile, are people disposed to pronounce an authoritative judgment regarding him. In all such cases a lively anecdote or sparkling witticism is too cheap and pleasant a method of settling a doubtful character not to be generally adopted. They commonly fall in with the conclusion which lies nearest to the surface, and being thus most easily come at, they are eagerly caught up and borne along from mouth to mouth till their mere repetition sanctifies the delusion out of which they sprung. One common character runs throughout all the anecdotes of which Rabelais is the hero. They show a mind without gravity or depth, giving the rein to its most wayward sallies, destitute of self-respect, and reckless either of present circumstances or of future results. Such is just the character which a superficial observer is likely to form of him from his own romance. The rhodomantade, the coarseness, the downright nonsense, the reckless exuberance of humour, are easily noted; whilst the vein of deep and earnest thought which ever and anon shows itself amid the surrounding extravagance, the infinite good sense, the high-toned and enlightened philanthropy, and the great moral purpose which the author had in view, escape the careless and unpenetrating eye. The vices which he has laid bare with such masterly tact have been set down as his own, and he is charged with having been a profligate, a debauchee, and a buffoon, devoid at once of self-respect and of reverence for whatsoever is sacred or noble. But everything which is authentically known of his life, not less than what may be inferred from a careful study of his works, goes to discountenance such a conclusion. He was beloved and respected by many of the most illustrious and virtuous prelates of his time, admitted into their most private councils, and charged with the most important trusts. All his works, except his romance, which, being a reflection of the time, must needs carry its grossness and licentiousness upon its front, are conceived in a uniformly grave and learned spirit; and in his letters, where certainly a light or ribald mind was most likely to have shown itself, there is nothing to be found unworthy of the scholar, the gentleman, and the churchman. These facts are utterly inconsistent with the charges of buffoonery, immorality, and irreligion which are usually coupled with his name; and assuredly, if his life had given any warrant for such charges, there were jealous enemies enough to have placed the fact beyond all doubt.

In common with the other great assailants of religious abuses, Rabelais was branded with the names of heretic and atheist, and the dedication of the fourth book of his romance makes an indignant allusion to the circumstance. Epithets like these, however, he could well afford to share with such men as Erasmus, Luther, and Melancthon. Had he escaped them, indeed, there would have been some cause for wonder; for assuredly the severest blow ever levelled against the abuses of the Roman Catholic Church was the publication of the *Chronicle of the Wondrous Deeds of Gargantua and Pantagruel.* The popularity of its form secured it attention, where a formal censure would have been disregarded; and it was read on every hand with unexampled avidity. Calvin spoke of part of it with asperity, but others of the Reformers, penetrating its real spirit, gave it their warmest approval, and Beza's well-known epigram has long graced every edition of the book.

Qui sic nugatur, tractantem ut seria vincat,
Cum seria faciet dic, rogo, quantus erit?

If he, who in his frolic mood
Outdoes the lore of toilsome sages,
Should don grave Wisdom's reverend hood,
What might be looked for from his pages?

"Beyond a doubt," says Coleridge, "he was among the deepest as well as boldest thinkers of his age. His buffoonery was not merely Brutus' rough stick, which contained a rod of gold; it was necessary as an amulet against the monks and bigots. Never was there a more plausible, and seldom, I am persuaded, a less appropriate line, than the thousand-times-quoted

'Rabelais laughing in his easy chair'

of Mr Pope. The caricature of his filth and zanyism proves how fully he both knew and felt the danger in which he stood. I could write a treatise in praise of the moral elevation of Rabelais' work which would make the church stare and the conventicle groan, and yet would be the truth, and nothing but the truth. I class Rabelais with the great creative minds of the world [Homer], Shakspeare, Dante, Cervantes, &c." The prevalent coarseness, though this even is not always without its meaning, of Rabelais' great work, makes it repulsive to the mass of readers; and this it is, probably, which has enabled modern writers to appropriate its thoughts and witticisms with impunity. But the richness of invention, the dramatic force of the characters, the originality and vigour of thought, the wit, the learning, the satire, poignant yet without cynicism, the wise philosophy, and the atmosphere of triumphant joyousness which invests the whole, justify the praises of Coleridge, and will secure its fame as long as vice remains to be lashed and folly to be ridiculed.

It is impossible not to admire the robust and healthy nature of the mind of Rabelais, which, at a time when earnestness was constantly running into extravagant excesses in the persons of the other great reformers of the period, maintained its equipoise, without losing any of its intensity in seizing and grappling with the predominant abuses. Nor is its moral culture less conspicuous, which, in an age when the face of society presented so much to impress a conviction of the farce and hollowness of the world, preserved him, in despite of his acute sense of the absurd, the false, and the contemptible, as well as of his strong satirical bias, from becoming a morbid and misanthropical reviler of mankind. "I ask not," says Coleridge, "the genius of a Machiavel, a Tacitus, or a Swift; it needs only a worldly experience and an observing mind to convince a man of forty that there is no medium between the creed of misanthropy and that of the gospel." Which of these, then, was the creed of Rabelais? Most certainly the latter. He hates cant in all its shapes, hypocrisy under all its disguises; tyranny, intolerance, villany, selfishness, and all its brood of tyrant vices, are his abhorrence; mere folly he makes his sport, and he dallies with absurdity with a very wantonness. But he never forgets that he, the satirist, is himself come of the stock of Adam, or libels the Creator by flying in the face of that nature which, good or bad, is still his gift. Rabelais takes life as it is; he would fain see it better, and lends a helping-hand to make it so. Like his great countryman Beranger,

"De l'univers observant la machine,
Il y voit du mal, et n'aime que le bien."

He detests the evil with which the world is overrun, but he never abandons his faith in the good. His satire is not the angry yelping of a currish nature, the overflow of sour secretions and accumulated bile. Where it is grave, it is the commanding voice of honest indignation; where jovial, its kindliness of tone makes you like the man, whilst you admire his genius. He is essentially kindly even in his severest moods; and this is apparent in the very form of his satire. Its most caustic strokes are given with a merry voice and laughing eye; and yet, whilst apparently revelling in the most unrestrained ebullitions of mere animal spirits and licentious fancy, he is covertly stripping sensualism of its enticements, and enforcing the strongest lessons of humility. He possessed, in short, the wisdom of love, which is "the creed of the gospel," and this his great romance testifies in a hundred places. At the same time, its defects are great and manifold, and these cannot be better summed up than in the words of La Bruyère:—"Rabelais is inexcusable in having scattered mere filth throughout his writings. His book is a chimera. It is the face of a beautiful woman with the tail of a serpent, or of some other still more unsightly monster. It is a monstrous jumble of a fine and delicately-wrought moral, and of the most offensive grossness. Where it is bad, it is as bad as can be,—the very scum of the world might batten on it; where it is good, nothing can be more choice or excellent; it *can* furnish most dainty fare."

For bibliographical details as to the works of Rabelais, see *Biographie Universelle*, tome xxxvi. The standard edition is that by E. Johanneau and Esmangart, Paris, 1823, 9 vols., which contains the *Songes Drolatiques*, a curious series of one hundred and twenty caricatures by Rabelais himself, illustrative of the characters of his romance. It also contains his letters and the *Sciomachia*, a work which had become extremely scarce. The two latter have been included in most of the editions, now very numerous, since published. Of these, that by MM. Burgand des Marats and Rathery is the best (Paris, 2 vols., Didot, 1858). A careful memoir of Rabelais will be found there, and also in Niceron's *Mémoires des Hommes Illustres*, and Chauffepié's Supplement to Bayle. Rabelais has been naturalized amongst ourselves, more successfully, perhaps, than any other foreign writer, by Sir T. Urquhart and Motteux's admirable version of his romance. (T. M.)

RABENER, GOTTLIEB WILHELM, a German satirist, born in 1714 near Leipsic, and studied law at the university of that city. While holding a civil office at Dresden he commenced to write satires upon men and manners. An observant eye and a humorous and benevolent disposition qualified him in an especial manner to be the censor of social follies and vanities. His descriptions were faithful, vigorous, and good-natured; and his style was correct, pointed, and flowing. Accordingly he attained a a high reputation as a satirist. During his lifetime his works passed through several editions, and were translated into French and Dutch. After his death in 1771 they appeared in an eleventh edition, in 6 vols. 8vo, Leipsic, 1777. They have now a historical value as a record of habits and modes of life which have passed away.

RACCONIGI, a town of the kingdom of Sardinia, province and 11 miles N.E. of Saluzzo, in a rich and beautiful plain, near the right bank of the Maira, 21 miles S. of Turin. A walled town, with broad regular streets, and substantial good houses, it is chiefly remarkable for the noble palace and extensive park belonging to the family of Carignan, now the royal family of Sardinia. There are also several churches and convents, a college, military and other schools, hospitals, &c. Silk is extensively manufactured here, and forms the staple of a considerable trade. Pop. 10,500.

RACES OF MAN. See ETHNOLOGY.

RACHEL, the name by which a celebrated French tragèdienne is ordinarily known, was the daughter of Abraham Felix and Esther Haya, both of Jewish race, and was born in a wretched little inn in Munf, in the canton of Aran in Switzerland, on the 24th of March 1821. Her father was a poor pedlar, who pursued his craft by the highways till he succeeded in housing his numerous progeny in Lyons, where her mother opened a paltry little second-hand clothes shop. Sarah, the eldest child, sang from café to café, and Rachel collected the coppers. Towards 1830 the family removed to Paris, and continued the life they had led in Lyons. Shortly afterwards, Rachel seems to have found interest to recommend her to St Aulaire, manager of an institution where pupils were taught declamation gratuitously; and in 1837 this meagre, dark, poverty-stricken little girl, with her harsh gruff voice, found an engagement with M. Poirson at 3000 francs for three years. On the 12th of June 1838 she made her first appearance on the classic boards of the Théâtre François, where she was destined to earn her greatest fame. From this date her progress was upwards and onwards. The grand old formal drama of Corneille and Racine, so long believed to be dead, revived again at the splendid declamation and singular attitudinizing of this new tragic muse. She was the organ of the great classic poets; and, accustomed to the pomp and grandeur of the sounding Alexandrine, her clear, distinct enunciation brought out every beauty in bold relief; but unfortunately it did the same with every fault. She had not the power of concealing under the warmth of delivery the meagreness of the author's style, and M. Samson could not teach her *that*. Her best characters were probably "Phedre," "Roxane," "Camille," "Lyciska," and "Lady Tartuffe." When the old drama began to pall at the Théâtre François, modern characters were created for her, in which, however, she very rarely succeeded. The managers gave her an enormous salary, yet this did not content her; she was almost constant in her quarrels with them. She dictated her own terms, and kept the authors whom she lured to write for her in a perfect fever. In her acting she was terrible rather than touching, and she was often far from being true. Her tears had the bitterness of Marah in them, and very rarely excited tears in her audience. She never melted or awakened sympathy; but she always inspired the spectator with wonder and fear. The love of gold was born with her, and swam in her Jewish blood. Her graspingness had one redeeming feature, and that was, that she permitted her family to share in her gains. She had few real friends, and those she had were new. She was a woman of real genius, but that genius, though of a very high order, was very limited in its range. During her *congês* she visited professionally London, St Petersburg, Amsterdam, Germany, Rome, and the French provinces, and finally made a tour to America, which so aggravated the disease under which she was labouring that on her return she sought the shores of the Mediterranean, and died at Cannet on January 4, 1858. Her disease was consumption. Rachel was never married, yet she left behind her two sons, who were old enough to know their loss. (*Memoirs of Rachel*, by Madame de B——, 2 vols., were published in London in 1858.)

RACINE, a town of the United States of North America, capital of a county of the same name in the state of Wisconsin, on level ground, about 40 feet above Lake Michigan, on the west shore of which it stands, 23 miles S.E. of Milwaukie, and 62 N. of Chicago. It is regularly built, with broad straight streets, and contains many good public buildings. In a grove of trees, somewhat to the south of the town, stands the Episcopal college, a fine Gothic structure of pale brick. Besides several Protestant and Roman Catholic churches, Racine contains a high school, conspicuous in the centre of the town, and three other public schools. The harbour is one of the best on the lake, and admits vessels drawing 12 feet. The chief manufactories of the town are ship-yards, furnaces, machine-shops, and flour-mills. The total value of the principal articles manufactured in 1855 was L.230,133. The trade is great and rapidly increasing, especially in timber from the west; the exports and imports in 1851 amounted together to L.522,438. Pop. (1850) 5111; (1853) about 7500; (1857) about 11,000.

RACINE, JEAN, an illustrious French poet, was born at Ferté-Milon on the 21st of December 1630. He was the son of Jean Racine, controller of the salt magazine of that city, and of Joan Sconin, daughter of the king's warden of the woods and waters of Villers-Caterets. Deprived of his father and mother at the early age of three, he passed under the guardianship of his paternal grandfather, also named Jean Racine, who, not long afterwards, bequeathed the trust to his widow. He studied first at

Beauvais; next at Paris, in the college of Fearcount; and lastly at Port-Royal-des-Champs, whither a number of eminent persons had retired to devote themselves to piety and the instruction of youth, amongst whom were the advocate Lematire, Dr Hamon, Nicole, A. Arnauld, Lacy, and Launcelot, authors of the *Logic*, the *General Grammar*, and other works, known under the title of *Methodes de Port-Royal.* Launcelot, in particular, undertook to teach Greek to the youthful Racine. But besides the taste for sound literature and serious studies, these immortal solitaries inspired their pupil with those religious principles which never abandoned him, and which were common to all the great writers and great men of that age. The docility of Racine towards his masters equalled his ardour for study. On one occasion, however, he showed himself refractory. Having accidentally met with the Greek romance of *Theagenes and Chariclea*, he commenced the perusal of this work of fiction, when his master, surprising him while thus engaged, took from him the book and consigned it to the flames. The youth procured another copy, and learned it by heart, after which he placed it in the hands of Launcelot, saying, "You may burn this also." An act of disobedience of a kind so novel, was the more readily excused because it was not likely to have many imitators.

The first poetical essay of Racine was *La Nymphe de la Seine*, an ode which he composed for the marriage of Louis XIV., and which having made him known to Chaplain, the temporary arbiter of literary reputations and court favours, produced him 100 louis, which Colbert sent him on the part of the king; and not long afterwards he received a pension of 600 livres. Four years later, towards the close of 1663, another ode, *La Renommée aux Muses*, composed on the occasion of the establishment of the three academies, procured for him a second royal gratuity, the order for which was couched in terms peculiarly flattering to the youthful poet. This ode, though inferior to the preceding, was nevertheless more fortunate. Recompensed like the other by the king, it had the good fortune to be criticised by Boileau. The poet took an early opportunity to thank the critic, and this proved the origin of that connection so intimate, so honourable, so useful to Racine, and which was not one of the least advantages which fortune gave him over Corneille. A little before this period Racine had made the acquaintance of Molière, and had communicated to him a tragedy entitled *Theagène et Chariclée*, taken from the romance which had afforded him such delight at Port-Royal. Molière, disapproving of this production, gave him the plan of the *Thébaïde, ou les Frères Ennemis*,—a subject on which it is alleged that he had himself been engaged. Racine executed the design, and the piece had some success. *Alexandre*, which was performed the following year (1665), met with a still more favourable reception, and showed great progress in the versification of the author, who was then only twenty-five years of age; but, excepting the verses, neither of these works gave any indication of what Racine afterwards proved. They were but feeble imitations of Corneille, of whom, by a misfortune common to all imitators, Racine had only adopted the defects,—that is, the cold gallantry mixed with heroism, the idle maxims, the metaphysical reasonings, and the elaborate declamation. Corneille, to whom Racine read his *Alexandre*, counselled him, it is said, to write no more tragedies. At a subsequent period the same advice was given to Voltaire by Fontenelle after the reading of *Brutus.* But it is fortunate for letters that such counsels are never followed. Voltaire replied to Fontenelle by the production of *Zaïre*, and Racine responded to Corneille by that of his *Andromaque.* Finding himself pursuing a wrong direction, he suddenly changed his route and took a different one, unknown perhaps even to Corneille himself. The latter had astonished and surprised his audience; his young rival sought to move and to soften them. Pity appeared to him a tragic resource more active, more extensive, and of an effect more penetrating and less transitory than admiration. He studied the human heart, its passions, its weaknesses, and its most secret recesses, and there he discovered a species of tragedy altogether new, of which he gave the first and probably most inimitable model in his *Andromaque*,—that one of all his tragedies which, without being the most perfect, produces the greatest effect on the stage by the vigorous and just expression of the sentiments and characters, and by the alternations of hope and fear, of terror and pity, with which the poet agitates the soul.

The representation of the *Andromaque* in 1667 was followed almost every year by a new masterpiece. But at first Racine surprised the public by an excursion into the domain of Molière. The *Plaideurs*, imitated from the *Wasps* of Aristophanes, is a comedy the plot of which is somewhat feeble and inartificial; but in nature, truth, facility, and gaiety, it is admirable, and its verses became so fixed in the general mind that they passed into proverbs. The piece was first represented at Paris in 1668, when it was indifferently received; but it succeeded pretty well at Versailles, and the players, elated with the success, came to awaken Racine in the middle of the night, to communicate the good news. The noise of vehicles at such an hour in the Rue des Marais, convinced first the neighbours, and next day all Paris, that justice had avenged itself on the author of the *Plaideurs*, by causing him to be seized and sent to the Bastille. This pleasant mistake, and the knowledge which soon became general, that the comedy had obtained the suffrage of the monarch, conciliated the favour of the loyal Parisians; and from that time the piece has continued in possession of the stage, privileged to extort a smile, perchance a laugh, even from the iron visage of Justice herself. It is not true, as has sometimes been said, that the *Plaideurs* is the work of several hands. Racine may have received from his friends hints or suggestions for some scenes, and borrowed from certain *hommes de palais*, or gentlemen of the robe, some formulas and expressions foreign to his habitual studies; but the unity of the style and the general coherence of the whole are too perfect to be the work of any but one and the same hand.

The success of *Andromaque*, which was only equalled by that of the *Cid*, had excited envy; perhaps, also, it had rendered the public fastidious. In 1669 *Britannicus* was coldly received, and with difficulty reached the eighth representation. At first no one felt the truth, the depth, and the force displayed in the magnificent historical picture of Nero and his court. Boileau alone was struck with its merit, and hurrying to embrace Racine, he exclaimed, "Voila ce que vous avez fait de mieux." This great critic was not only useful to Racine in praising his performance; his severity was of full more service in inducing him to suppress two scenes which deformed his work,—one between Burrhus and Narcissa, at the commencement of the third act, and another in the fifth, in which Junia is brought back into the presence of Nero. *Britannicus* was followed by *Berenice*, which, in some respects, is one of the most remarkable of Racine's works. At the solicitation of the celebrated Henrietta of England, Racine and Corneille both treated this subject, which is so little fitted for representation, neither being aware that the other was engaged upon it. Besides the pleasure of seeing two illustrious rivals unconsciously contending for the palm, this princess secretly promised herself another, in the treatment of the heroic separation of the two august lovers; but a premature death deprived her of the pleasure she had anticipated, in witnessing this singular competition. Three words of Suetonius represent the subject of the piece: *Invitus invitam dimisit;* too slight a foundation upon which to work, and in the case of Corneille, who was now old, an ungrateful task, far more dangerous to him than even to Racine. The two rival plays were represented towards the close of 1670; that of Corneille at the Palais-Royal, by the company of Molière, and that of Racine at the Hôtel de Bourgogne. Corneille's totally failed; that of Racine had thirty consecutive representations, during which it drew tears alike from the court and the city. The great Condé replied to some criticisms which were made in his hearing in the following verses of the piece itself:—

> Depuis cinq ans entiers chaque jour je la vois.
> Et crois toujours la voir pour la première fois.

It has been said, and even zealous admirers of Racine have confessed, that *Berenice* was not a veritable tragedy. But, tragedy or drama, what signifies the title which may be given to it, provided we be agreed that it is a miracle of art, and that never, in any piece, were greater difficulties more meritoriously overcome. The style possesses exquisite beauties in detail, and an inexpressible charm pervades the diction throughout.

Bajazet appeared in 1672, and obtained immediate success, partly, no doubt, from the novelty of the manners and costumes, but in a greater degree from admiration of the force and truth with which the poet had delineated the characters of Roxana and Acomat; two real creations, which in spite of all its faults, will make *Bajazet* immortal. At the same time, there is not a little truth in the remark of Corneille, that though the costumes be Turkish, the characters are French. *Mithridate*, which was represented for the first time in January 1678, is, according to Laharpe, the work where Racine appears to have come nearest to Corneille in bringing on the stage the great personages of antiquity as they are delineated in history. Few characters, indeed, have, upon the whole, been more vigorously traced than that of Mithridates; and were it not that Racine, sacrificing to the taste of the time, has made the hero amorous and jealous, Corneille would not have enjoyed unquestioned supremacy in reviving and re-animating history. Voltaire regards *Iphigénie*, first represented in 1674, as the masterpiece of the stage. Do we desire grandeur? We find it in Achilles. Do we wish for true policy? It is exemplified in the part of Ulysses; a policy founded solely on the love of the public good, and equally adroit, dignified, and resolute. Clytemnestra is the model of the lofty pathetic; Iphigénia, that of noble and touching simplicity. Agamemnon is as he should be; and, then as to the style, Voltaire has declared it to be the true sublime. Three years elapsed between the appearance of *Iphigénie* and that of *Phèdre*, which was first represented in 1677. The former had been the object of sundry ill-natured and depreciatory criticisms; but all these were only a feeble essay, or rather a mere foretaste, of the attacks which were now directed against the latter, chiefly at the instigation of the Duke de Nevers and the Duchess de Bouillon, nephew and niece of Cardinal Mazarin, the declared enemies of Racine, though for what reason does not appear. Every engine was put in action to ensure the condemnation of Racine's *Phèdre*, and extol to the skies that of Pradon, a person of no genius, and whose name is not worth remembering, except that he was employed by the chiefs of his odious cabal to have a drama on the same subject ready for representation against the time when Racine's was to appear. Pradon lent himself to the vengeance of these intriguers; his *Phèdre* was represented four days after that of Racine; and, for the moment, the cabal were successful. But, in about a year, each piece found its natural level, and Pradon and his *Phèdre* were alike forgotten or despised.

This tardy reparation, however, could not console Racine; and, besides, it was poisoned by new indignities, which were heaped upon him by his indefatigable enemy. Disgusted with the theatre, where he had met with such injustice, he now determined to renounce it for ever; though not more than thirty-eight years of age, and still in all the vigour and maturity of his genius. Besides, in his infancy, he had imbibed a deep sense of religion, which, suppressed for a while by his connection with the theatre, now returned in full force. He conceived that his past life had been full of errors, nay, even tainted by vices and under this impression he not only resolved to write no more plays, but had even thoughts of devoting himself to penitence and prayer in monastic solitude. His spiritual guide, however, justly distrusting a zeal springing out of wounded feelings, advised him to marry and settle in the world; and this judicious advice Racine had the good sense to comply with. In the year 1677 he married the daughter of the treasurer of Amiens, a fortunate choice, which greatly contributed to his future happiness. He next effected a reconciliation with the solitaries of Port-Royal, whose censures of dramatic composition, which had formerly offended him, he now acknowledged. He first made his peace with Nicole, who received him with open arms; and Boileau introduced him to Arnauld, who also embraced him tenderly, at the same time freely forgiving him all his satire. About the same time Louis XIV. appointed Racine and Boileau historiographers of France, upon the understanding, of course, that they were to write the history of his reign; and the public expected great things from two writers of such distinguished reputation. But both the king and his subjects were equally disappointed. Boileau and Racine, after having for some time laboured at the work, perceived that it was entirely opposite to the genius of each; and they also judged, with reason, that the history of such a king could not, and indeed ought not, to be written until long after his death, unless it were to be made up of extracts of gazettes and such like materials.

During a period of twelve years Racine had steadily adhered to his resolution not to write any more poetry, especially for the stage; but the entreaties of Madame de Maintenon so far prevailed as to induce him to resume his dramatic character, and in consequence he composed his *Esther*, which was to be represented, not on the French stage, but in the house of Saint-Cyr. On the 20th of January 1689 it was performed for the first time, and had prodigious success. "It appears to be very remarkable," says Voltaire, "that this tragedy should then have had universal success, and that two years afterwards *Athalie*, though performed by the same persons, had none. It happened quite otherwise when these pieces were acted at Paris long after the death of the author, and when prejudice and partiality had ceased. *Athalie*, represented in 1717, was received, as it deserved to be, with transport; whilst *Esther*, in 1721, inspired nothing but coldness, and never appeared again. But at that time there were no courtiers who complacently acknowledged Esther in Madame de Maintenon, and with equal malignity saw Vashti in Madame de Montespan, Haman in M. de Louvois, and, above all, the persecution of the Huguenots by this minister, in the proscription of the Hebrews." The same writer, who had no taste for scriptural subjects, thinks the story of *Esther* uninteresting and even improbable; "but, notwithstanding the badness of the subject," he adds, "thirty verses of *Esther* are of more value than many tragedies which have had great success."

Athalie, composed, like Esther, for Saint-Cyr, had, as already intimated, a very different fate. Envy masked under a false zeal prevented the representation. It was only performed twice at Versailles, in a chamber without scenes and costumes, by the ladies of Saint-Cyr. Racine having originally intended it for publication, now sent it to the press; but, to the eternal disgrace of the age and nation, this masterpiece of sublime genius, unsurpassed either in ancient or in modern times, found no readers; and, in some societies of pretended wits the perusal of it was ironically prescribed as penance. It is in truth lamentable to think that Racine should have descended to the grave suffering under this injustice, and with the bitter feeling of seeing his age dissatisfied with his immortal work. In vain did Arnauld, from the depth of his solitude, try to sustain, by his suffrage, the sinking spirits of his old pupil; in vain did Boileau repeat, "C'est notre meilleur ouvrage, le public y reviendra." Racine almost believed that he had survived his genius, and the authority of Boileau, so potential with posterity, was disregarded during the lifetime of his friend. This second injustice of the public towards Racine reopened the wound inflicted by the first, completed his disgust, and decided him to abandon definitely writing for the theatre, which, in fact, his religious impressions had for some time led him to regard as incompatible with the Christian life. He accordingly withdrew from all connection with the stage, and employed the remainder of his days in the grateful and almost filial task of composing a history of Port-Royal, the place of his education, which is drawn up with equal taste and elegance, but was not published till 1767, when it appeared in two volumes 12mo.

Racine, although he had conversed much with the court, had not learned to disguise his sentiments, the usual, perhaps the necessary, accomplishment of a courtier. In 1697, during one of those interviews which Madame de Maintenon frequently granted him, the conversation having turned upon the misery of the people exhausted by long wars, and the best means of affording them relief, this celebrated woman entreated the poet to throw his ideas on the subject into the form of a memoir, promising that the writing should not pass out of her hands. Racine consented, not from the mere complacence of a courtier, and still less from any ambitious view, which the whole tenor of his life contradicts, but solely with the design of being useful. The king surprised this memoir in the hands of his mistress, and the name of the author was disclosed. Perhaps the lesson was a little too direct, since the monarch, who had all along favoured the poet, immediately took offence. "Because he makes good verses," said Louis, "does he think he knows everything? and because he is a great poet, does he pretend to be a statesman?" Racine was greatly hurt by this observation, not from any selfish consideration, but from the idea of having unnecessarily offended his royal benefactor. But to say as some have done, that it shortened his days, is manifestly absurd. His constitution had for several years been sinking under the wasting influence of excitement, and, in consequence, the term of his earthly career was now fast approaching. During his last illness, however, the king evinced the greatest interest in the expiring poet, about whom he daily sent to make the most anxious inquiries; and his benefits followed him even beyond the tomb. Racine died on the 22d of April 1699, after much suffering, borne with truly Christian fortitude, and was interred, according to his wish, at Port-Royal, at the feet of Dr Hamon, that he might not be separated even in death, from the master whom he so loved and respected in life. After the destruction of this monastery, his remains were transported to Paris, and deposited in the church of Saint-Etienne-du-Mont, where they were placed beside those of Pascal.

Racine was naturally melancholy when alone, though gentle and pleasing when in company. His nature was tender and affectionate, inclined to indulge sorrowful or religious emotions rather than those which spring out of mirth or joy. He was generous, and knew how to preserve the means of being so by much order and economy. He afforded assistance to a number of distant relations, and had a regard almost filial for his nurse, whom he did not forget in his will. There was no better husband, no more affectionate father. The Christian education of his children formed his chief concern. He had family prayers daily, at the same time reading and explaining a portion of the gospel to his wife, his children, and his domestics. During the last ten years of his life all his pleasures and all his happiness were concentrated in his domestic circle. He no longer went to court except when called thither by the duties of his charge and the interests of his family; and yet who else could boast of the same means of pleasing and making himself beloved; his fine and noble figure, his gracious manners, all the charms of wit, all the splendour of renown, united with the happy art of causing them to be forgotten? He was indeed what the ladies of Saint-Cyr described him, a man of great genius and great simplicity; and he had in fact enchanted the world more by the amenity and grace of his instructions than by his talent for declamation, which, however, he possessed in the very highest degree. No man of his time read and recited better than Racine. One day, at Boileau's, in his house at Anteuil, reading and translating off-hand the *Œdipus* of Sophocles, he drew tears from all present. He also taught Baron and La Champmâlé a system of declamation more conformable to nature and good taste than that which they had previously practised; in short, he taught them to speak and not to declaim.

As to his works, his countrymen have reason to be proud of them. He is the poet of the heart and the affections, and yields to none in the truth, the beauty, and the force of his delineations. If Corneille surpassed him in heroic sentiments, and the grand character of his personages, he was inferior to Racine in moving the passions, and in purity and harmony of diction. Such is the perfection of Racine in this last respect, that in all his pieces there is not perhaps, we do not say a scene, but even a single verse, which could be replaced by another. All is just and true; all is full of that poetry of images and sentiments, and that continued elegance which, since the time of the Greeks, Virgil and Racine have almost alone possessed. But above all, it is in *Esther* and in *Athalie*, particularly in the choruses of these two tragedies, that, sustained by the most sublime models, he is himself almost always sublime. It is there that Racine has all the elevation of a Hebrew prophet who had come to announce divine truths in strains almost divine. But that which chiefly characterizes Racine is the complete union, perhaps unique, of two qualities which appear to be incompatible; of imagination the most brilliant and reason the most perfect, of sensibility the most exquisite with good sense the most invariable. Reason, in fact, as much, and even more perhaps, than imagination, predominates in the conception of his most touching productions, in the execution of his most dramatic scenes, in the choice of his richest expressions, and in his boldest combinations, as well as most elliptical turns. Boileau, who has been surnamed the "poet of reason," is not even in this view, superior to Racine; and, besides, the quality here mentioned is the less astonishing in him, because it is accompanied with an imagination much less lively. Racine has often been pronounced the greatest of the French poets. He should also be set down as the most rational; or rather, it is precisely because he really is the most rational, in the widest sense, that he is likewise the greatest.

There are some smaller pieces of Racine which have not been mentioned in the course of this article, particularly *Idylle sur la Paix*, 1685; *Discours prononcé à l'Académie Française*, en 1685; *Cantiques Spirituelles*, 1689; and *Epigrammes Diverses*. The most complete edition of the works of Racine is that published by Aimé Martin at Paris, in 6 vols. 8vo, in 1820, reprinted by Lefèvre in 1822.

RACING. See HORSE.

RACK, an engine of torture, furnished with pulleys, cords, and other means, for extorting confession from criminals. It was known from an early period in the south of Europe, where it was applied to the early Christians, and was in later times an instrument of the Inquisition. The trial by rack is unknown to the law of England; though, in 1423, when the dukes of Exeter and Suffolk, and other ministers of Henry VI., had formed a design to introduce the civil law into the kingdom as the rule of government, they erected a rack for torture, which was called in derision the "Duke of Exeter's Daughter," and still remains in the Tower of London, where it was occasionally used as an engine of state, not of law, in the reign of Queen Elizabeth. But when, upon the assassination of Villiers, Duke of Buckingham, by Felton, in 1628, it was proposed in the Privy Council to put the assassin to the rack in order to discover his accomplices, the judges, being consulted, declared unanimously that no such proceeding was allowable by the laws of England. The most fearful piece of torture on record is that of Ravailliac, the murderer of Henri IV. of France. (See Ravailliac.) The Marquis of Beccaria, in an exquisite piece of raillery, has proposed this problem:—"The force of the muscles and the sensibility of the nerves of an innocent person being given, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime."

RACZ-KEVE, a market-town of Hungary, on an island in the Danube 28 miles long and 1 or 2 broad, in the county and 22 miles S.S.W. of Pesth. It has a fine palace, built by Prince Eugene of Savoy. Pop. 4650.

RADCLIFFE, Ann Ward, author of the *Romance of the Forest* and the *Mysteries of Udolpho*, was born in London on the 9th of July 1764. At the age of twenty-three, she acquired the name which she subsequently rendered famous, by marrying William Radcliffe, a graduate of Oxford, and then a student of law. This gentleman renounced the prosecution of his legal studies, and afterwards became proprietor and editor of the *English Chronicle*. Mrs Radcliffe having thus a strong inducement to cultivate her literary powers, first came before the public as a novelist in 1789, in the *Castles of Athlin and Dunbayne*. Her genius, however, was more advantageously displayed in the *Sicilian Romance*, which appeared in 1790, and attracted a considerable share of public attention. The *Romance of the Forest* appeared in 1791, and at once raised the authoress to that pre-eminence in her own style of composition which her works have ever since maintained. In 1798 Mrs Radcliffe visited the scenery on the Rhine, and it is supposed that the *Mysteries of Udolpho* were written, or at least corrected, after the period of this journey; the mouldering castles of the robber-chivalry of Germany, situated on the romantic banks of that celebrated stream, having, it is thought, given a bolder flight to her imagination, and a more glowing character to her colouring. Her remarks upon the countries through which she travelled were given to the public in 1793, under the title of a *Journey through Holland*, &c. This, however, was merely a sort of intercalary production. The next production by which Mrs Radcliffe attracted the attention of the public was destined to be her last. The *Italian*, which appeared in 1797, was purchased by the booksellers for L.800, and favourably received by the public. The tenor of her domestic life was peculiarly calm and sequestered. She appears to have declined the notoriety which in London society usually attaches to persons of literary distinction. During the last twelve years of her life Mrs Radcliffe suffered from a spasmodic asthma, which considerably affected both her health and spirits. This chronic disorder, however, at length took a more fatal turn on the 9th of January, and on the 7th of February 1836 it terminated her life. (For an estimate of her works, see Romance.)

Radcliffe, *Dr John*, an English physician of great eminence in his time, was born at Wakefield in Yorkshire in 1650. He was educated at Oxford, and enrolled himself as a student of physic; but it was remarked that he recommended himself much more by his ready wit and vivacity than by any extraordinary acquisitions in learning. He began to practise at Oxford in 1675, but never paid any regard to established rules, which he censured whenever he thought fit with great freedom and acrimony; and as this drew all the old practitioners upon him, he lived in a state of continual hostility. He died in 1714; and if he never attempted to write anything himself, he has perpetuated his memory by founding a fine library at Oxford, named after its founder the "Radcliffe Library," and which cost the sum of L.40,000. (See Libraries.)

RADETZKY DE RADETZ, Count Joseph, an eminent Austrian field-marshal, was born in Bohemia in 1766, and entered the Austrian army in 1784. The outbreak of the great continental war against the French soon gave him an opportunity of achieving distinction. His soldier-like qualities then came into notice. Courage and coolness appeared as inherent parts of his nature, which he could not lose. In victory or defeat he was always the same—ever steady and ever valiant. He distinguished himself in the successful battle of the Trebbia in 1799. He was one of the foremost of the victors at Novi in the same year. Even in the disastrous rout of Marengo, in 1800, he did not forego his self-possession. Nor did his ability fail to rise to the high offices of command which were at length assigned him. In 1813 he was the main instrument in gaining the victory of Kulm; in the same year he drew up the plan of the decisive battle of Leipsic; and in 1814 he rode into Paris side by side with the Emperor Alexander. But the greatest achievement of Marshal Radetzky was the part which he took as commander-in-chief in Lombardy, in suppressing the Italian insurrection of 1848. It is true that at first the suddenness of the rebellion threw him off his guard. After three days of barricade fighting, the Milanese forced him to retire from their city; the Sardinians, under King Charles Albert, followed up the advantage; and he was obliged to fall back upon Verona. Yet all this while, like a wary veteran, he was assiduously concentrating his strength for the recovery of the ground he had lost. A sudden and successful recoil was the result. The Italian forces were driven back and dispersed; one post after another was re-captured; on the 6th of August Milan was entered; and on the 24th of March 1849 the insurrection received its death-blow at the battle of Novara. The veteran Radetzky was now handsomely rewarded for these valuable services. Twenty-six cities presented him with their freedom; every continental potentate showered honours upon him; and his own sovereign continued to cherish him with grateful affection till his death, in 1858. (See *Eine Biographische Skizze nach den eigenen Dictaturen und der Correspondenz des Feldmarshalls von einem Œsterreichischen Veteranen*, von J. G. Cotta'scher Verlag, Stuttgart and Augsburg, 1858.)

RADHUNPOOR, a native state of India, under British protection, lying in the N.W. of the province of Gujerat, between N. Lat. 23. 26. and 23. 58., E. Long. 71. 28. and 72. 3.; length, about 40 miles; breadth, 20; area, about 800 square miles. It is watered by the River Bunnos and other streams, and enjoys a soil generally fertile, and a climate which, though excessively hot during the summer months, and again after the rains of August and September, is for the rest of the year mild and agreeable. Salt is obtained here; and the principal products of the soil are cotton, wheat, and other kinds of corn. The state came under the British protection in 1819, when the Nawab applied for aid against the marauders who infested the country. This was granted, and, in return, an annual tribute exacted, which was remitted in 1825, on account of the inability of the state. No tribute is now paid; but the external relations of the country are controlled by the British agent at Pahlunpoor, leaving its domestic affairs entirely free. Pop. 45,000, chiefly Hindus.

The capital, a fortified town of the same name, 85 miles N.W. of Ahmedabad, and 270 S.E. of Hyderabad, is a place of some manufactures and commerce, though its inhabitants are for the most part engaged in farming. Coarse cotton cloth is made; and, along with corn, hides, butter, &c., exported. Pop. 15,000.

RADIUS (*a ray*, or *the spoke of a wheel*), the semidiameter of a circle, or a right line drawn from the centre to the circumference.

RADNORSHIRE, an inland county of Wales, lying nearly midway between the southern and northern extremities of the principality on the English border. It is bounded on the north by the counties of Montgomery and Salop, on the east by Hereford, on the south by Brecknock, and on the west by Brecknock and Cardigan. Its outline is an irregular oval, with a rounded protuberance on the north-west. Its greatest length from south to north is about 30 miles, and from east to west, measuring across the protuberance on the north-west, about 33 miles. It possesses an area of 425 square miles, or 272,128 acres, and is thus tenth in order of size of the Welsh counties. The Welsh name is *Sir Faesyfed*.

The greater portion of this county rests upon the Silurian group of rocks, but there are some tracts of old red sandstone on the east, and throughout the county there are considerable patches of feldspathic ash and greenstone, and on the eastern part, near the town of Old Radnor, there is a large patch of Silurian limestone, which is much used for dressing the land in the neighbourhood.

This district of country continued under the jurisdiction of the Lords Marchers until it obtained the privileges of a county by act of Henry VIII., and was divided into the hundreds of Radnor, Knighton, Painscastle, Rhayader, Coluyn, and Cefn Llys. By the same act it was also empowered to return two members to Parliament, one for the county, and one for the contributory boroughs of Radnor, Rhayader, Knighton, Knuclas, and Cefn Llys. The county is further divided into parishes and townships. The former are fifty-two in number, and all are in the diocese of St David's, except five, which are included in the English diocese of Hereford. New Radnor, said to have been at one period the principal town, is now a very poor village; it was an ancient borough by prescription, and has also had charters granted by Queen Elizabeth, and by George II.

Two-thirds of the whole area of the county are supposed to be uninclosed and uncultivated. An extensive mountainous tract, nearly in the centre, is usually called the Forest. A part of this range still belongs to the crown, although the forests of Radnor and Blathvagh have both been alienated, and are now held by Sir George Cornewall Lewis and Lieut.-Col. Price as foresters. No part of the range attains any great elevation. Its highest summit was ascertained by Colonel Mudge to be 2163 feet above the level of the sea. Within its limits is a torrent, called by a name which, when translated, is "Water-break-its-neck," that falls abruptly from a height of about 150 feet. The higher ranges produce only heath; but the sides and lower parts of the hills, which are less exposed to the winds, are entirely devoted to the pasturage of sheep and small horses. The north-western angle of the county is mountainous and uninclosed, and it was into the recesses of these wilds that the British monarch Vortigern retreated from the Saxons. In the eastern and southern districts the valleys are wider and more fertile, and abound with small rivulets; while the hills are less elevated, and are partially clothed with wood.

The soil of the county is chiefly an open shaly clay, which in sheltered situations yields, under good cultivation, excellent crops of turnips, oats, and Welsh barley. In the east there is an admixture of the red sandstone soils, which are of great fertility and of a loamy character.

The climate is wet and stormy, and the spring months are particularly cold and ungenial. It is nevertheless healthy; there are no peculiar or prevalent diseases, and the inhabitants are robust and long-lived.

The principal river is the Wye, which enters the county at Savan-y-Coed, and, flowing in a south-easterly direction, divides this county from Brecknock. Its tributaries are the Elau, the Ithon, the Edw, and the Marteg. The River Teme forms the county boundary on the north-east, and continues its course by Ludlow to the Severn. The Lug and the Arrow, in the more central parts, form considerable streams before they enter the county of Hereford. There are some small lakes or pools requiring notice only as contributing to the beauty of the scenery. These are,—Llyn-Llanbychllyn, Hendwell Pool, and Llyn-Gwyn. A cataract at Rhayader was formerly an object much visited by travellers; but the construction of a bridge has widened the channel, and deprived it of much of its remarkable character.

The agriculture of the county is gradually improving. Irrigation has long been practised to a considerable extent, and its effects on absorbent soils are found to be highly beneficial; but the process is not conducted in the most scientific manner. The ploughing was formerly usually performed by two oxen and two horses; but oxen are now seldom used, and the plough with two horses is in gradual adoption. Most of the farms consist of an equal portion of arable and of grass land. The latter is generally appropriated to the dairy, and the young cattle are reared on the more hilly and barren spots. About one-fifth of the county is under the plough, and one-tenth meadow; the remainder is chiefly occupied as sheep-walks. Large numbers of cattle, chiefly of the well-known Hereford breed, are annually reared; and these, with Welsh sheep, ponies, and butter, form the staple of the agricultural exports.

There is little commerce carried on in this county, as might be anticipated, from its remoteness and difficulty of access. There are some woollen manufactures carried on, chiefly of coarse cloth and flannel.

The county is not known to contain any valuable minerals. A lead mine has been opened and abandoned, and in some places an uncertain belief has prevailed of the existence of copper. Various mineral springs are known; and Llandrindod is a place of great resort on account of the medicinal qualities of its saline, sulphurous, and chalybeate wells. In several other parts there are similar springs, the properties of which have not been accurately ascertained.

In Radnorshire there are many vestiges of antiquity. The abbey of Cwm Hir stood formerly in a singularly retired and romantic situation on the banks of a rivulet which runs into the Wye. A small vestige remains of a castle at New Radnor, which was assailed and destroyed "by the irregular and wild Glendower," previously to the battle noticed by Shakspeare, in the first part of Henry IV., when Mortimer was taken prisoner. It was fought at Pilleth in this county. A Roman road, which reached from Chester to Caermarthen, traversed this county, entering its confines on the northern extremity, in the direction of Newtown, following the valley of the River Ithon, and crossing the Wye into Brecknockshire near the town of Builth. At Cwm, near Llandrindod, the remains of a Roman station on this road are still discernible.

This county returns one member to Parliament, and has done so since 1536. The district boroughs of Radnor, Cefn-Llys, Knighton, Knucklas, Rhayader, and Presteign returns another. The political influence is in the hands of Sir George Cornewall Lewis, Colonel Price of Norton Court, and the De Wintons of Maeslough. The famous Harley, Earl of Oxford, represented the Radnor boroughs from 1690 till 1711.

The population, by the census of 1851, was 24,716, of which number 12,693 were males, and 12,023 females. This gives 58 persons to a square mile, or 11 acres to each person; thus proving it to be the most thinly-peopled part of Wales, or indeed of England and Wales. The number of inhabited houses in 1857 was 4614; uninhabited, 217; building, 28; giving 11 houses to a square mile, and 5·4 persons to a house. The population had decreased in the ten years previous to 1857 by nearly 700 persons. The amount of real property assessed for the income-tax in 1857 was L.146,072; the amount of property assessed for relief of the poor was L.111,007. It is calculated that upwards of 18 per cent. of the population live by agriculture; nearly 8 per cent. by trade, manufactures, &c.; 50 per cent. of the whole are in the condition of labourers and servants; only 100 persons follow professions, and about 800 possess independent means.

In 1847 there were in this county 43 day-schools for the working-classes, attended by 1381 scholars, and 53 Sunday-schools, attended by 2309 scholars; of these 1146 were at Church of England Sunday-schools, and 1163 at dissenters' schools, chiefly Methodist. In 1847 it was ascertained that there were only from 2500 to 3000 persons in this county who could not speak the English language, out of a population of 25,000, while in the adjoining county of Cardigan only 3000 could speak English, out of a population of 70,000. (J. G.)

RADOM, a town of Poland, capital of a government of the same name, 56 miles S. of Warsaw. It is walled and defended by a castle. There are here a court of law, public offices, two churches, two convents, a piarist college, a gymnasium, &c. Pop. (1854) 10,231.

RAEBURN, Sir Henry, the Reynolds of Scotland, was the son of a manufacturer, and was born at Stockbridge, Edinburgh, on the 4th of March 1756. The circumstances of his early life were far from being propitious. He was only six years old when he was left an orphan. The elder brother, who undertook the charge of him, could not afford to keep him long at school. He was accordingly apprenticed, at the age of fifteen, to a goldsmith in a dingy alley of the old town of Edinburgh. Yet in spite of these disadvantages, the genius of the boy began, by its own innate strength, to assert itself. In the workshop of his master he took insensibly to sketching. Whenever the tools were laid down, the pencil was in his hand drawing caricatures of his companions. The growing habit soon ensured success, and success incited him to higher efforts. In course of time he was painting miniatures, which attracted the interest of some of his fellow-townsmen. David Martin, a popular portrait-painter, gave him encouragement, and lent him pictures to copy. People began to sit to him for their likenesses in miniature. His own master, recognising a great artist in what he formerly thought a mere idle shop-boy, absolved him from his apprenticeship, and allowed him to devote himself entirely to painting. Encouraged by these favours, the young enthusiast continued assiduously to study the principles of his art. He had mastered the difficulties of colouring; he had abandoned miniatures for portraits in oil; and he was earning a comfortable livelihood with his brush, when an incident occurred which was the means of accelerating his rise towards excellence and fame.

One day when Raeburn was out in the fields quietly sketching, a young lady sauntered into the landscape which he was drawing. Her appearance pleased him, and he put her down upon the paper as an enlivening accessory to the scene. Not long afterwards, much to his delight and surprise, the same young lady appeared at his studio to sit for her portrait. A mutual impression was the consequence; and before many months had elapsed she gave him her hand and a handsome dowry along with it. Thus furnished, by a happy incident, with competent means, Raeburn now resolved to devote himself to a more thorough study of his art. Accordingly, he set out along with his wife to make himself acquainted with the paintings of other countries. The object of his journey was successfully pursued. On arriving at London he had the good fortune to gain the approbation and friendship of Sir Joshua Reynolds. The kind-hearted president sent him to Rome with letters of introduction to the most eminent artists in that city, and with the advice to study Michael Angelo in the Sistine chapel. Full advantage was taken of both the counsel and the introductions; and at the end of two years he returned to his native city greatly improved, and set up his easel in George Street.

Raeburn now entered upon a career of portrait-painting surpassing everything of the kind that had hitherto been known in the Scottish capital. The great principle of his art was to endeavour, if possible, to represent the intelligence as well as the mere flesh of the human countenance. To achieve this object, he found it necessary to bring into play all the resources of his generous and highly-gifted nature. These, therefore, he employed in a very able and successful manner. No sooner were sitters admitted than, with his gentlemanly demeanour and frank address, he put them completely at their ease. They sat down on his platform too much fascinated with his conversation to be capable of looking affected and unnatural. The talk continued as he commenced to paint. He led them on from one subject to another until he had brought them to their favourite topic, and detected the highest expression of which their features were capable. Then he put that expression down upon the canvas, and finished the rest of the picture accordingly. The portraits painted in this manner went forth among the public to establish the fame of the artist. Their boldness of posture, vivacity of mien, and breadth of effect, put to shame the works of all his competitors. In no long time he was the acknowledged prince of Scottish portrait-painters, and had the finest heads and faces of the land for the subjects of his brush. The rank and intellect of the nation became his sitters. He had the honour of painting the severe shrewdness of the grandees of the south, and the martial air of the plaided chieftains of the north. He had the still higher honour of delineating the noble foreheads and thoughtful eyes of the chiefs of literature and science. In fact, there was scarcely an eminent Scotsman of the age of Blair and Hume whose portrait did not go forth to the world on his canvas, immortalizing the names of both the subject and the artist. Nor, at the beginning of the nineteenth century, when that generation had passed away, did Raeburn cease to be the painter of genius. In his new studio in York Place he depicted another race of great men, not inferior to their illustrious predecessors. There he executed those portraits of Henry Mackenzie, Sir Walter Scott, Francis Horner, Lord Jeffrey, and Lord Cockburn, in which their originals still seem to think and speak.

The life of Raeburn drew to a close amid circumstances of great prosperity. The fame of his genius had spread to foreign countries. His name was in the list of the Royal Academicians. His supremacy among Scottish artists was acknowledged by a knighthood from George IV. in 1822. At the same time, the vigour and healthy enthusiasm of his fine nature remained unimpaired. There was not an hour of the day which was not devoted to one or other of his favourite pursuits. He made experiments in mechanics and ship-architecture. He worked in the garden of his villa of St Bernard's. He superintended the building of that suburb at Stockbridge which was afterwards called Raeburn Place. He likewise laboured at his easel with all the ardour of his first love, painting portraits which surpassed the masterpieces of his prime. Thus was his green old age spent, until a short and painless sickness brought it gently to a close on the 8th July 1823. (See Chambers' *Biog. Dict.*, and Cunningham's *Lives of British Painters, &c.*)

Raffaelle.

RAFFAELLE, RAFFAELLO, RAFAEL, or RAPHAEL, SANZIO, was born at Urbino, in the Papal States, on the 6th of April 1483. The family patronymic had been originally *De Santi* or *Sancti*, but custom had gradually worn it into *Sanzio*. His father, Giovanni Sanzio, like others of his kindred at Urbino, was a painter of moderate ability, and what was still better, was possessed of a noble modesty which enabled him to foresee and acknowledge the future glory of his immortal son. Raffaelle was a painter from his cradle. He played with the implements of his father's art, and in no long time he exhibited a talent for drawing of such extraordinary precocity that his father chose for his master the most renowned painter of the day, Pietro Vanucci, called "Il Perugino." From the first he displayed a wonderful facility, and while engaged on the same canvas with his master the entire piece seemed the product of one hand. At the end of three years, business called Perugino to Florence, and Raffaelle, with the blessing of his generous master, set out at the age of seventeen to try his fortune with his pencil. The paintings executed by him at this early period, though very much in the manner of Perugino, display a subtle grace and delicacy altogether peculiar to himself. He visited Florence in 1504, where Leonardo's "Battle of the Standard" and Michel Angelo's celebrated "Cartoon" gave him much to study, and taught him how much he had still to learn. Raffaelle is commonly reported to have lost his parents before he was twelve years old; but this supposition is shown to be entirely groundless by the letter of introduction which he received from the Duchess of Urbino, dated October 1, 1504, and addressed to the gonfaloniere Soderini of Florence. In that document her ladyship alludes to his father as still living: "and as I know his father," she says, "who is dear to me, to be a virtuous man," &c. Raffaelle was at that period in his twenty-first year; but how long afterwards that "virtuous man" was permitted to watch the rising star of his son's fame we have no means of knowing. How very much he seems to have profited by what he saw and heard at Florence is abundantly evinced by his exquisitely beautiful pictures of that period, some of them very elaborate, as "The Entombment of Christ." They display a grace and a power of expression which was quite remarkable, and almost entirely new to Italian art. Pope Julius II. invited him to Rome towards the end of the year 1508, where he remained till his death. He commenced work on the Camera della Segnatura, and executed his figures of Theology, Poetry, Philosophy, and Justice on its ceiling, before undertaking the larger paintings which were to adorn its walls. In simplicity and beauty, in severity and dignity, in energy of execution and in beauty of individual character, the "Disputa del Sacramento" has never yet been surpassed. This is the character of nearly all his subsequent productions: they stand unrivalled in composition, and in grandeur of conception they have never been equalled. As a painter, sculptor, and architect,—in short, as a perfect master of design,—Michel Angelo knows of no equal; while Raffaelle, who was solely a painter, lavished all the treasures and various excellence of an uncommonly gifted nature on his art; in grandeur and in grace, in delicacy and in softness, in the strength of man and in the elegance of woman, he displayed every quality that can by any possibility distinguish a great painter. He died at the early age of thirty-seven, on the 7th of April 1520. His pictures number in all about 128, besides a large number of drawings which are scattered throughout various parts of Europe. An estimate of his works will be found in the articles ARTS, *Fine*, and PAINTING. Besides the works of Lanzi and Vasari, the reader may consult *The Life and Works of Raffaello*, by Quatremère de Quincy, translated into English by William Hazlitt, jun., London, 1846.

Raffles.

RAFFLES, SIR THOMAS STAMFORD, the son of a captain in the West India trade, was born at sea off the coast of Jamaica on the 5th of July 1781. Returning with his mother to England, he was placed in a boarding-school at Hammersmith, where he remained till the age of fourteen, when he entered the East India House as an extra clerk. While employed there, he occupied his leisure hours in various kinds of acquirements, and particularly in studying languages, for which he gave proofs of possessing great facility. In 1805 the directors of the India House having resolved to found a new settlement at Penang, or Prince of Wales' Island, on the coast of Malacca, for the purposes of trade, Raffles had risen so steadily in their good opinion that he was appointed assistant-secretary to that establishment. On his voyage out he acquired the Malay language, which stood him in good stead a short time afterwards, when, owing to the illness of the chief secretary, Raffles had to undertake the entire labour of arranging the forms of the new government, and of compiling all public documents connected with it. Such an accumulation of work proved too severe for his constitution, and in 1808 he had to visit Malacca to recruit his shattered strength. Here he enjoyed large opportunity of mingling with a very varied population congregated from all quarters of the Eastern Archipelago and the distant Asiatic continent. He likewise made the acquaintance of Marsden and the lamented Leyden, and in company with these two orientalists he began his elaborate researches into the history, the laws, and the literature of the Hindu and Malay races. In zoology he took a special interest, and ultimately became founder, on his return to England, of the Zoological Society, of which he was the first president. While on a visit to Calcutta in 1809, Raffles suggested to Lord Minto, then governor-general of India, the desirableness of wresting Java from the French, and rendering it a British possession. The governor-general grasped the idea with vigour; and ere many months had passed away a fleet of 90 ships dropped anchor before Batavia in August 1811. A short time effected the conquest of the island, and annexed Java to our East Indian dominions. Stamford Raffles was made lieutenant-general of the new territory, and resolved, at whatever cost, to give to the island, which had been subjected so long to the selfishness of a horde of Dutch robbers, a pure and upright administration. There were three sources of abuse which he resolved to eradicate. These were—the revenue system, the system of police and public justice, and the abolition of the slave trade. In a period of only five years Raffles had almost effected his design; he was adored by the native Javanese; all classes of society mentioned his name only with praise; and the revenue was eight times larger than it had been under the Dutch. However, the policy of some of his measures was considered doubtful by the home authorities, and he was in consequence recalled. Raffles reached London on the 16th of July 1816, and on his laying his case before the Court of Directors of the East India Company, they saw it expedient to express their conviction that the measures which he had adopted had "sprung from motives perfectly correct and laudable." To meet the growing demand for information about Java, he published a *History of Java*, in 2 vols. 4to, 1817.

Having received the honour of knighthood from the prince regent, Sir Stamford Raffles set out for the island of Sumatra as lieutenant-governor of Bencoolen or Fort Marlborough, a small district in the south-west of the island that belonged to Great Britain. He arrived at his new destination on the 22d of March 1818, and immediately set to work to abolish slavery, and gradually to liberate the convicts who had been transported thither. Anxious for some new settlement where some accredited British authority might be stationed to afford protection to British shipping, Sir Stamford

Raffles proceeded to Calcutta to consult the Marquis of Hastings, then governor-general of India. The marquis approved of his plan; and Sir Stamford proceeded down the Straits of Malacca, and on the 29th of February 1819 the British flag was waving over Sincapore. Returning to Bencoolen, he found that society was improving, and the foundations of good order were fairly laid. Sir Stamford and Lady Raffles began now to look forward to a return to England. They had sacrificed three children to the climate, and they were anxious for the safety of their remaining daughter. Before taking leave, however, of the Eastern Archipelago, he resolved to visit Sincapore, his “political child,” and see what progress it was making towards prosperity. He arrived there on the 10th of October 1822, and occupied himself for nearly a year in laying out the new city, and in establishing institutions and laws for its future constitution. It was expressly provided, among a multitudinous array of details, that Sincapore should now and for ever be a free port to all nations; that all races, religions, and colours should be equal in the eye of the law; and that slavery should have no existence. Java had been given up to the Dutch shortly after Sir Stamford left it, and now Bencoolen was granted to them in exchange for Malacca. A short time before the latter arrangement had been completed, Sir Stamford Raffles and his lady had landed in Plymouth. A most disastrous event occurred on setting sail from Sumatra on the 2d February 1824. The ship Fame, when about 50 miles from land, suddenly took fire. The crew and passengers were with difficulty saved. The loss to Sir Stamford was beyond all repair. The whole of his drawings, all his collections in botany and zoology, all his papers and manuscripts, of which there were many volumes, fell a prey to the flames. His pecuniary loss amounted to more than L.20,000. During one of his excursions into the interior of Sumatra, in company with the lamented Dr Arnold, he came upon the largest and most magnificent flower in the world, the *Rafflesia Arnoldi*. In 1820 he sent home a large collection of preserved animals, now in the museum of the London Zoological Society, and a paper containing a description of them was read before the Linnæan Society, and published in their *Transactions*. He died on the 5th of July 1826, in the forty-fifth year of his age.

RAEGANJ, a town of British India, in the presidency of Bengal and district of Dinajepoor, on the left bank of the Kooluk, 32 miles W. of Dinajepoor, and 292 N.W. of Calcutta. Its narrow, crooked, and dirty streets are generally crowded and bustling; for the town is a place of considerable trade, and forms the chief emporium for the fertile region around it. Pop. estimated at 5000.

RAGLAN, James Henry Fitzroy Somerset, *Baron*, the eighth son of the fifth Duke of Beaufort, was born in 1788, and entered the army in 1804. His military training was received under the Duke of Wellington. Becoming one of the aides-de-camp of that general in 1808, he continued during the rest of the French war to serve him with great efficiency and acceptance. On all occasions he was one of his great chief's most trusted advisers. In times of action, too, his cool courage and daring valour were notable. He was among the foremost combatants at every battle, and experienced a full share of the honours and perils of the war. At the storming of Badajoz he was one of the first to mount the breach; at Busaco he was slightly wounded; and at Waterloo he lost his right arm. Fitzroy Somerset next appeared in an administrative character. He was secretary to the embassy at Paris from 1816 to 1819. Then the Duke of Wellington, holding at that time the office of master-general of the ordnance, made him his secretary; and when appointed commander-in-chief in 1827, still retained him in the same capacity. No sooner had the term of that office expired in September 1852, than other appointments began to flow in upon him. He was promoted to the post of master-general of the ordnance, and was elevated to the House of Peers with the title of Baron Raglan. He was also acting as a privy councillor when the outbreak of the Russian war in 1854 summoned him to a higher sphere of duty. Lord Raglan now entered upon his office as commander of the British forces in the Crimea. His conduct in that tedious and disastrous campaign (of which a detailed account is given under Russia) was worthy of one who had been trained under Wellington. There was not in the entire expedition a single critical occasion during which his calm courage did not appear to advantage. At the battle of the Alma his French colleague St Arnaud declared that “his bravery rivalled that of antiquity.” During the fight of Balaklava he was seen coolly reconnoitring in front of his own lines, and within range of the enemy's guns. In the great battle of Inkermann it was his promptness in bringing a few guns into play which contributed in a great measure to check and rout the overwhelming masses of the enemy. Even the disasters of the ensuing winter, although they brought discredit upon his capacity as a general, did not impair his fortitude and firmness of purpose. He continued to act with magnanimity and energy, in spite of the dreadful misfortunes on the field and the clamorous discontent at home. It was not till after the severe repulse of the allies on the 18th June 1855 that his mental anxiety became too great for his brave spirit, and brought his life to a close on the 29th of the same month.

RAGMAN'S ROLL (*ragman*, an indenture or legal deed), the name given to the collection of those instruments by which the nobility and gentry of Scotland were compelled to subscribe allegiance to Edward I. of England in 1296. This document, which consists of four large rolls of parchment formed by stitching together 35 smaller pieces, is kept in the Tower of London, and was published in Prynne's *Records* (pp. 648–665), and more recently under the auspices of the Bannatyne Club in 1834.

RAGUSA, a town of Austria, formerly the capital of an independent republic which now forms part of the kingdom of Dalmatia, stands on a peninsula on the E. shore of the Adriatic, 40 miles N.W. of Cattaro. It is built partly at the foot and partly on the steep slope of two hills; and is defended by walls and bastions, and by several forts. The streets, generally narrow, are well paved, and lined with large and substantially-built houses. The finest buildings are the cathedral, the former Jesuits' church, and the beautiful Gothic episcopal palace. The manufactures consist chiefly of silk and woollen cloth, wines, tobacco, and soap. The trade and navigation of the port are considerable; and ship-building is carried on. Ragusa was originally founded by fugitives from the neighbouring Epidaurus, when that city was destroyed by the Slavonians. The constitution was republican, the executive being in the hands of a senate elected by a general council, and presided over by a supreme officer, called at first Count, but subsequently Rector. Until the tenth century Ragusa was under the protection of the princes of Narenta; afterwards, however, it became an independent and powerful maritime state. For more than a hundred years it was governed by Venetian rectors; but in 1368 it was made independent of that state by the King of Hungary, under whose protection it continued to flourish At a subsequent period Ragusa became tributary to Turkey. It was taken possession of by Napoleon in 1806, and on his fall in 1814 it came to Austria. Pop. 8800.

Ragusa, a town of Sicily, on the right bank of a river of the same name, in the province and 29 miles W.S.W. of Syracuse. Manufactures of cloth and silk are actively carried on; and there is much trade in the corn, oil, wine, and cheese produced in the vicinity. Pop. 16,800.

RAIKES, Robert, the founder of Sabbath schools in

England, was born at Gloucester in 1735, and succeeded his father as proprietor and conductor of the *Gloucester Journal.* The swarms of profane and vicious children let loose upon the streets of Gloucester on a Sunday long engaged his serious attention; and he resolved that some scheme should be tried for putting an end to this evil. Persons were employed to open a Sunday school in the locality. Every effort was made to induce the children to attend. The school in a short time was crowded; and before his death in 1811, he had the satisfaction of seeing several similar institutions established in most of the large English towns.

RAILWAYS.

Railways for the most part belong to the order of contrivances. The first man who, noticing the facility with which the bole of a tree rolled down a slope, converted it into a roller for the movement of heavy bodies, would very soon discover that, to gain the greatest facility of movement, it is essential to have a path free from all inequalities and prominences; and he would discover also that it was essential for his roller to be a true cylinder if he wanted it to move straight and easily. The difficulty of maintaining a soft surface as a straight surface would soon present itself, and he would lay down the boles of straight trees in the line of his path. Here, then, we have the earliest railway, still used by timber-cutters in wild countries. Light sticks of round timber are laid down for the rails. Other sticks are formed into rollers as a crude kind of wheels to run on them, and on the rollers are placed the trunks of massive trees which are required to be moved from the forest. A modern contriver has gravely proposed a modification of this as a means of transport for army stores and guns on an expedition.

But the boles of trees have soft and hard sides, arising from atmospheric influence while growing. Therefore they cannot long maintain their cylindrical form. Moreover, it would soon be discovered that a cylinder can only move forward in a straight line, and that the taper bole of a tree can only move forward in a circular line. Neither condition would fulfil the requirements of a crooked road with constant change of direction; and the next contrivance would be to divide the roller into two separate cylinders, capable of rolling independently of each other. This would be the germ of modern wheels. Another contriver would discover the advantage of connecting them together by a central bar around which they could revolve; but the load would still be borne on the peripheries of the rollers, on account of the difficulty of making an axle sufficiently strong and sufficiently free from friction to bear a heavy load. For this latter reason, in Spain, Portugal, Italy, and other rude districts, cars are still found in which two wheels are made fast on one shaft, which revolves with the wheels, without any power of independent movement on the wheels, and with a consequent enormous increase of resistance arising from differing diameters, eccentricity, polygonality, and other circumstances. Upon hard stony roads the resistance is almost destructive of utility, and it may be doubted whether a sledge would not be more useful. In Madeira a sledge kept moist by water is found to be actually preferable. Our modern railways have not yet attained to the condition of using perfect wheels. Rollers, in fact, not wheels in the correct sense of the word, are used thereon, similar in principle to the rude carts of rude countries: the wheels are keyed solidly on the axles, making one piece; and they are practically sledges wherever the path is uneven.

In the mineral districts of England, when coal and iron were dug, and had to be transported seaward, rollers, of necessity, soon gave place to wheels, after the cost of pack-horses had rendered this mode of conveyance impracticable. Wheels formed of wood could not last long, by reason of the wear of their peripheries, and, as a matter of necessity, gave rise to another contrivance in the form of strips of iron, or tyres, fastened to them. The meaning of the word "tyre" is something fastened round,—as attire round the body, tiara round the head, a tier of guns round a ship or fort.

A pair of wheels to a two-wheeled cart running on a bad road require to be of considerable diameter, and consequently weight. The difficulty of keeping a road in repair when in constant use from coal or iron mines would lead to many devices, and amongst others, doubtless, to laying planks or timbers at the bottom of the ruts, as a better contrivance than filling in stones. The inconvenience of the ruts, again, led to placing planks or timbers on the level surface; thus making a way or moveable road between the mine and the seaport, by leave or permission of the intermediate proprietors; and hence they are called "way-leaves." On these way-leaves, carts with two wheels were not convenient, and the way'n, wain, wagon, or waggon, with four wheels, was substituted. The planks forming the path for the wheels were, as a matter of course, connected by cross timbers, and thus a space was inclosed, from which apparently comes the term *rail,*—a cognate probably of apparel, which applies to dress and also to the tackle of a ship; also raiment and night-rail, expressing clothing which incloses the person. Probably the semblance of the timbers in form to the rails of a post-and-rail inclosure may have supplied the nomenclature.

The coarse make of the wheels would soon begin to abrade the timber, and we learn that it became a common practice to nail down strips of iron on the surface of the ascents, where the draught was increased by the use of the timber. Then a practice obtained of fixing down double rails,—a supporting rail below and a wearing rail above it,—to be taken up and replaced when too much worn. (See fig. 1.)

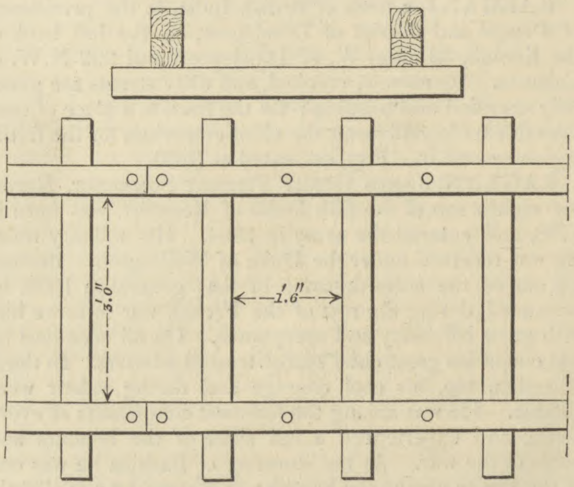

Fig. 1.
The Primitive Railway: Way-leaves.

The rapid wear of timber led to the structure of cast-iron rails to replace the wooden ones, and being limited in width, they were formed with a continuous flange or ledge on their inner edge, to keep the wheels on the track. (See fig. 2.) The roads were then called *tram-roads,* having been first laid down, it was said, by Outram, from whose

Mechanical Idea.

name, omitting the first syllable, the word is said to have been derived. The derivation would apply equally well to the word trammel—the rail-flanges being in reality trammels to guage the road and confine the wheels.

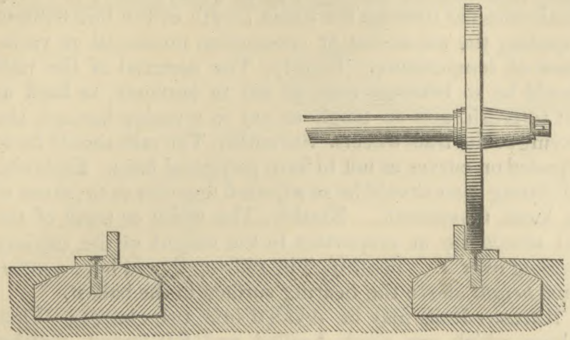

Fig. 2.
The Tram-Road, 1776-1800.

The leading objection to this system, the once famous tram-road, was, that the rail was liable to be covered with dust or gravel. Jessop, in 1789, to obviate these disadvantages, laid down at Loughborough cast-iron "edge-rails," from which the grinding ledges were removed, and applied round the edges of the wheels, forming flanges, the rails being elevated sufficiently to allow the descending flange to clear the ground. (See fig. 3.) This appears to have been the first system of rails laid on cast-iron chairs and on sleepers. The rails were pinned or bolted into the chairs.

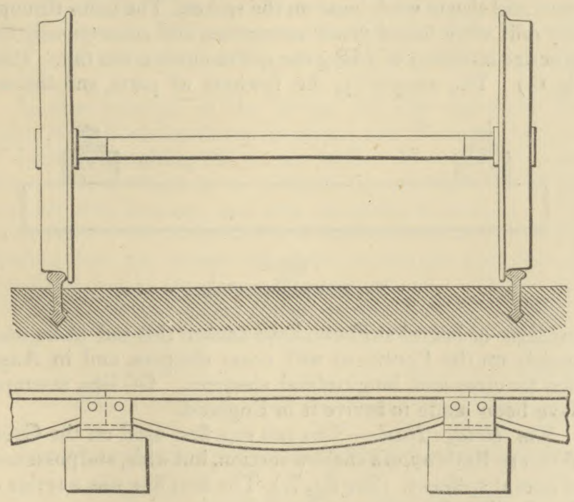

Fig. 3.
The Edge-Rail, 1789.

The substitution of rolled wrought-iron rails for cast rails was patented by Birkenshaw in 1820, as the "fish-belly" rail, similar in form and mode of support to Jessop's rail, but rolled in continuous lengths, embracing a number of spans, with stiffening ledges or flanges on the under side. This form of rails grew into favour, and was adopted in the construction of the Liverpool and Manchester Railway, which was opened in 1829. The rail weighed 33 lb. per yard, and was laid in cast-iron chairs, spiked down to square stone blocks at three-feet bearings. (See fig. 4.) It was fortunate for the country that this, the first important line of railway, had been entrusted to the consummate practical skill and experience of George Stephenson. The Liverpool and Manchester Railway, which descends to succeeding ages as a monument to his memory, happily served as a model railway for those which more immediately succeeded it. His son Robert Stephenson, and his pupils, were entrusted with the execution of several of the most important lines; and the same successful results which had attended the first railway were secured for those which came into operation afterwards.

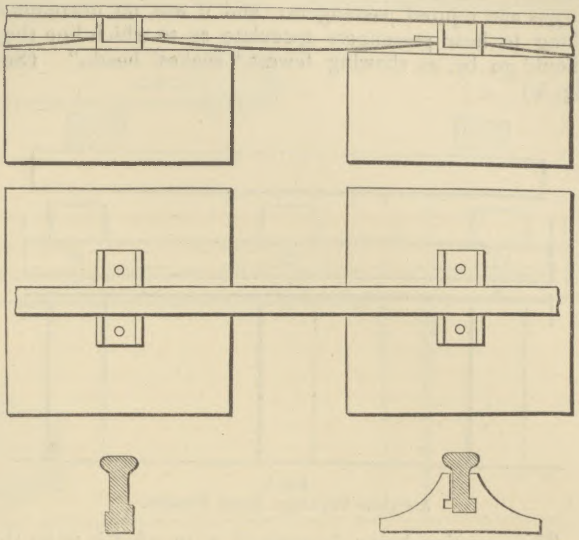

Fig. 4.
The Fish-Belly Rail, 1820.

The edge-rail and the flanged wheel are happily matched; they constitute essentially the mechanical idea of a railway,—the basis of the whole system.

Permanent Way.

PERMANENT WAY.

Guage.—The guage or measure of a railway is taken at the distance apart of the upper surfaces or treads of the two rails forming a line of rails, or a way. In England there are two guages, known as the "narrow guage," 4 feet 8½ inches, and the "broad guage," 7 feet between the rails. The narrow is the national guage of Great Britain, having been employed by the elder Stephenson for the Liverpool and Manchester Railway, and thereupon adopted for other lines, with a few exceptions, the most important of which is the broad guage, 7 feet, introduced by the younger Brunel on the Great Western Railway. The other exceptional guages have been reduced to a uniformity with the narrow guage. The Irish guage is uniformly 5 feet 3 inches, 6½ inches wider than the English guage, giving extra room for the construction of rolling stock. The European guage is for the most part the same as the English; but the Spanish is wider, 5 feet 6 inches, constituting a break of guage with France; commercially inconvenient, but supposed to be politically expedient. The Indian guage also is 5 feet 6 inches. The American guage is various, from 4 feet 8½ inches to 6 feet; some of the guages differ about an inch, and they interchange rolling stock, which of course runs tight and loose, but they blunder through it. The English national, or Stephenson guage, is practically of sufficient width.

As in all roads, the first consideration is the use to which a railway is to be applied, and the weight and damaging power of the wheels that are to run over it. A very common mistake is to make the road too weak for its work—to save materials and labour at the cost of destruction. This has been largely the case with American roads; their earliest system on the Baltimore and Ohio was a series of transverse timbers, on which were laid longitudinal timbers, trenailed down to them, to which was spiked a flat bar half-an-inch thick by 2½ inches wide, with counter-sunk spike heads. In the process of running the trains the iron was

Permanent Way.

curved, the spikes loosened, and the ends of the bars turned up, and were known by the technical name of "snake's heads." Occasionally they pierced the bottoms of the carriages and injured passengers; and it was no uncommon thing to hear passengers speculate as to which line they should go by, as showing fewest "snakes' heads." (See fig. 5.)

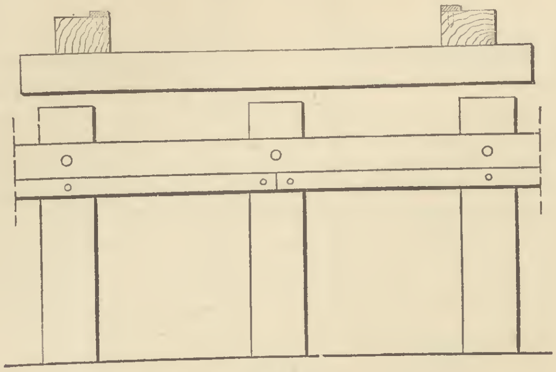

Fig. 5.
American Tramway: Early Practice.

The question being determined as to what is to be the weight of engines and trains, and their distinctive forms, the whole structure must be calculated on that as a datum-line. The most damaging part of the train being the driving wheels of the engine, that is the chief point to look to. It is desirable, if possible, not to exceed five tons on each driving wheel; if, therefore, heavy loads are required, four wheels must be coupled together; but in that case, though the load is distributed so as to avoid so much deflection of the road, the grind of the tyre and rail surfaces is increased, and speed is impeded by friction. An engine with two drivers will find less impediment than one with four. With a single driver the impediment would be at the minimum, supposing one of the wheels on the driving axle were loose. When two wheels are coupled, and *à fortiori* four, the diameters should be exact, and the rails also; if not, they will grind, and act as breaks. The workers of steam-coaches on common roads never used more than one fast wheel; if they did they broke their axles. The boys' toys called velocipedes, which work by cranked axles, have likewise only one fast wheel. The reason why the axles do not break more frequently is, that the rails afford facility for slipping.

The next consideration is, that the whole road be thoroughly well drained, that all rain-water falling on the line may have facility to run off the surface without soaking in, and that all running water crossing the line may be provided with culverts to pass below it. The sleepers or substructure should be bedded on at least 12 inches in depth of porous stone or gravel, constituting the ballast, without any clay or other material in it that may make a non-conducting bed. In many places natural ballast is not to be had, and where clay exists the process of burning it is resorted to. In districts where neither ballast nor clay occurs, as in the prairies of the United States, it is advisable to make such a bearing surface of timber, and such a strength of rail, so to distribute the load, that no sinking or pumping up and down could take place.

The level and the ballast being provided, the next consideration is that of the permanent way, the rails and their supports. Whether made in one form or another, the permanent way should, in the first place, have such an amount of bearing area on the ballast or ground as to prevent all sinking. Secondly, There should be such an amount of bearing area of the rail on the sleepers as to prevent all crushing. Thirdly, The rail should be so vertically stiff as to distribute the load over a great length without deflecting. Fourthly, The lateral stiffness should be ample to prevent all lateral deflection. Fifthly, The joints of the rails should be such as to produce a practically continuous bar through the whole length of the line without impeding the expansion or contraction incidental to variations of temperature. Sixthly, The material of the rails should be so homogeneous as not to laminate, so hard as not to crush, and so tough as not to crumble beneath the driving or the train wheels. Seventhly, The rails should be so adjusted on curves as not to form polygonal lines. Eighthly, All fitting parts should be so adjusted together as to permit of no loose movement. Ninthly, The width or tread of the rail should be in proportion to the weight of the engines running over it. Tenthly, The rail-top should have a *minimum height* above the bearing surface in the ballast.

Permanent Way.

RAILS.—Rails may be divided into two classes:—First, Those which are single-headed and flat-footed, forming their own support on the sleepers or ballast; secondly, Rails which are double-headed, and need chairs or other means of support on the sleepers. They may again be subdivided into:—Rails on cross sleepers of timber; rails on longitudinal sleepers of timber; rails on cast-iron sleepers without timber; rails on wrought-iron sleepers without timber.

The Flat-bottomed Rail.—This rail, with holes through the lower web to hold the spikes, was used to some extent both on cross and longitudinal timbers. The disadvantage was want of vertical stiffness in its ordinary form, and if made deeper it was apt to rock on the sleeper by reason of its small base, and also to work loose on the spikes. The holes through the rails were found disadvantageous, and subsequently the practice obtained of fixing the spikes outside the rail. (See fig. 6.) The simplicity, the fewness of parts, and the advantage of lateral stiffness, have caused this rail to be used largely on the Continent with cross sleepers, and in America for cross and longitudinal sleepers. Of late, attempts have been made to revive it in England.

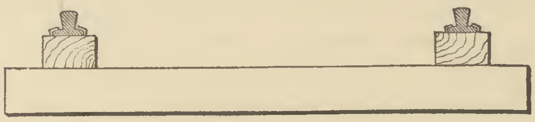

Fig. 6.
The Flat-bottomed Rail.

The Bridge Rail.—This rail was first used on the Great Western Railway, of a shallow section, but wide, and possessed of lateral stiffness. (See fig. 7.) The first line was a series of beech piles, 12 inches square, driven into the ground, to which were bolted at the surface level cross balks of timber, one on each side the pile-head on which they were shouldered. Longitudinal balks, 15 feet long, were laid on the cross balks. The longitudinals were covered with oak or elm planking screwed down to the surface. When the ballast was packed under the longitudinal balks, the surface of the oak planks was planed level, and the bridge rails screwed down on them, with felt between. It was supposed that there would be no yield whatever; but a very short time demonstrated that the piles formed a series of solid resistances, while the balks sprung between, and it was found necessary to cut away the piles. Transoms were then framed into the longitudinals, and secured by strap-bolts; and the whole resembled a long ladder laid on the ground. Eight different sections of rails were tried in succession; one section measured 1½ inch in height by 7 inches in width, weighing 44 lb. per yard; and the last section 2¾ inches high by 6 inches wide, and weighing 62 lb. per yard. The screws which held down the rails were counter-sunk be-

Fig. 7.
Bridge-Rail, first used on Great Western Railway.

neath the wheel flanges, and nut-headed on the other side. (See fig. 8.)

In consequence of the want of depth in the rails, they bent under the wheels, and crushed the timber in detail, though the total area of bearing was 5 inches in width, or 180 superficial inches per yard run. Had the rails been vertically stiff enough, the crushing would not have taken place. In fact the rails bent longitudinally, and the horizonal flanges curled up at the sides, and the holes through them bent into angles. One remedy tried was to cross-board the longitudinal timbers on the surface, and thus the fibre was less yielding.

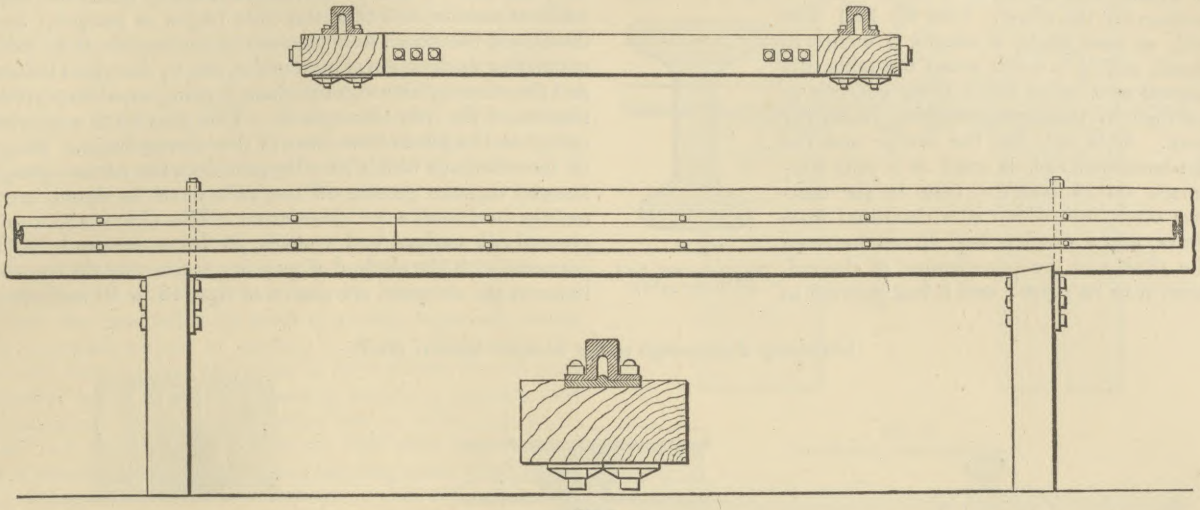

Fig. 8.
Recent Permanent Way of the Great-Western Railway (Bridge-Rail, 62 lb. per yard).

Another example of the bridge rail was applied by Sir John M'Neill on the Great Southern and Western Railway of Ireland, weighing 92 lb. per yard. It is laid on cross sleepers, into which it is notched by machine, the whole breadth of its bearing; and thus the guage is accurate. The cross sleepers are about 2 feet 6 inches apart, and the total bearing does not exceed 60 square inches per yard run, or one-third that of the Great Western system. Yet the rail does not crush the timber, partly because it does not deflect, and partly because it crosses the fibres of the timber. (See fig. 9.)

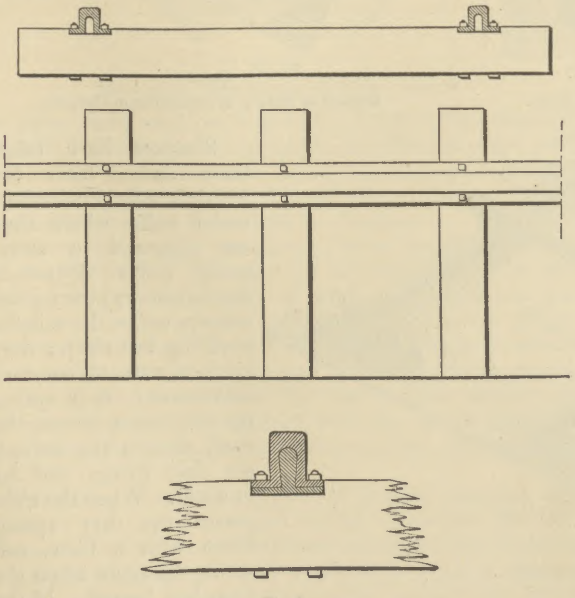

Fig. 9.
Permanent Way with Bridge-Rail on the Great Southern and Western Railway of Ireland (rail 92 lb. per yard).

On the Great Western the joints of the rails are supported by a piece of boiler-plate about 9 inches square, which was at first let flush into the timber; but being found to yield, it was subsequently laid on the surface, and pressed in by the running of the trains. It was secured by four bolts, two to each rail-end, the heads in the timber and the nuts on the rail flanges: they were quickly found to pull in and get loose. The bolts were then reversed, and long triangular fang-nuts were placed under the timbers: these also pulled in, and cast-iron nuts, measuring 4 inches by 2½ inches, were applied; the threads of these stripped, and they were replaced by wrought-iron of the same size. Thus the timber was as a packing between the upper joint-plate and the four nuts, comprising the same area. The rail-ends, however, still work loose, and the timber suffers.

The joint first applied by Sir John M'Neill was a dovetail fitting the hollow of the rail rivetted to a plate through which passed four bolts holding down the rail-ends. This worked loose, and the cross joint sleeper was continually splitting. This was, in fact, the defective part of the line. (See fig. 9.) An effective joint was subsequently applied, consisting of three castings, the centre one supporting the rail in the hollow, and two side clips holding the rail down by the angle of the flanges; the whole being connected by one or two side bolts fixing the three parts together in a wedge form, which makes a perfectly safe joint. (See fig. 10.) The bolted joint has also been adopted from the Great Southern on the Belfast and Ballymena Railway. Its horizontal area being considerable, it is sufficient to pack up the joint on the ballast, without using a cross sleeper under it.

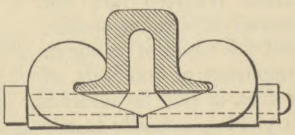

Fig. 10.
New Joint for Bridge-Rail.

The total height of this rail above the ballast is only 9 inches: it is very stiff vertically and laterally, and has little tendency to rock; but it is heavy, weighing 92 lb. per yard.

The Double-headed Rail.—We now come to the national rail of England, the double-headed rail, originated by Mr Joseph Locke, and first applied on the Grand Junction Railway, weighing 62 lb. per yard. (See fig. 11.) The top and bottom heads or tables of this rail are equal; it is more easy to roll than any other; and, if properly used, it is capable of being reversed, being in fact two rails in one. Formerly no means of fastening the rail to sleepers were employed except by

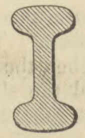

Fig. 11.
Double-headed Rail.

Permanent Way.

the agency of cast-iron chairs, and this has considerably damaged it, in fact and in repute; so that many engineers have been in the habit of late of making the lower table of smaller size, merely as a support, and not as a reversible surface for the wheel. (See fig. 12.) The rail, as now made, is usually 5 inches in depth, and 2½ in width across the table, the central web being about three-quarters of an inch in thickness, weighing 75 lb. per yard. This rail, like the bridge and the flat-bottomed rail, is used as a prop supported on its base; it rests in the cast-iron chair, into which it is deposited from above, and a wooden key, driven between the chair and the side channel of the rail, holds it in its place; and it is supported so firmly when newly inserted that it cannot get loose. (See fig. 13). Now, if it does not get loose, the chair and the rail will be as one piece, and no damage will occur. But practically the blows of the wheel-flanges laterally crush the key, which is outside, and then the rails begin to jump up and down, and the noise, so unpleasant to passengers, is an indication that destruction of both tables, one by the wheel below, and the other by blows on the chair, is going on, while crystallization of the iron takes place. This goes on to a greater extent in the joint-chairs than in the intermediates. Many of the accidents which have happened on the narrow-guage lines by engines getting off the rails have no doubt been mainly attributable to this cause. The chairs and compressed oak wedges and trenails, on Ransomes and May's patterns, with the method of guaging and boring the trenail-holes in the sleepers, are shown in figs. 13 to 19 inclusive.

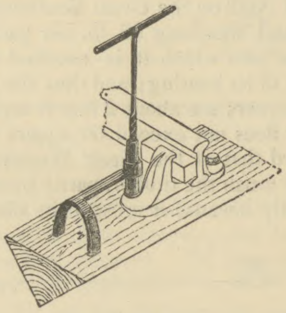

Fig 18.
Method of Boring Trenail-holes in Sleepers.

This rail has double the vertical strength of the Great Western rail, but laterally it is much weaker, and the mode of using it, supported at intervals of 3 feet, is not favourable. It yields plastically to the running of the trains, and is capable of being altered in form laterally by the packing of the ballast. It has also a disadvantage in its elevation above the bearing surface on the ballast. The rail is 5 inches, the chair 2 inches, and the sleeper 5 inches, —total, 12 inches elevation; and as the sleeper is only 9 to 10 inches in width, this induces a considerable rocking tendency in a forward direction. There is yet another consideration.

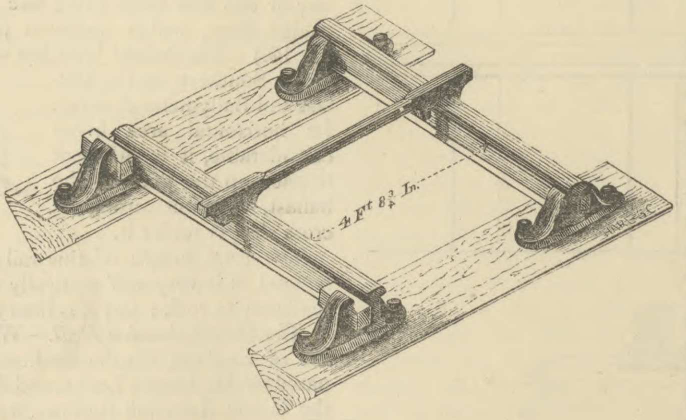

Fig. 19.
Method of Guaging Rails.

Sleepers have taken their name from the builders, who put timbers under walls, where they are supposed to sleep, being never disturbed. But in railway practice the timbers under the rails do anything but sleep; they are in a state of constant movement; they spring up and down across the road, disturb the ballast, set dust flying, and let in water. When the train passes by, they spring down with a blow, and spring up again when the train has passed. If the ballast be not porous and the weather be wet, a pond is formed beneath the sleeper which goes on increasing with every train; whilst the road cannot be meddled

Permanent Way.

with, as to open up the surface-ballast under such conditions is to make a quagmire for the reception of rain. To prevent the springing of the sleepers, it is required that they should be of greater size and strength, say 10 inches by 10 inches in width and depth; but this involves another difficulty. At present 12 inches depth of ballast must be dug out to get access to pack the sleepers below; and a really strong sleeper would make the depth nearly 18 inches, or the depth of the old stone-block. But according to former experience, the stone-block failed partly by rigidity, and partly because the height of the rail was so great compared with the base of the block. It was impossible to keep water from percolating below, and causing the block to subside unequally.

Joint Chairs.—It is obviously a great defect for a rail to lie loosely in an iron chair, but this defect is aggravated where the two rail ends meet in a chair, especially under the increased weight of modern engines. The most important consideration therefore is, so to secure the rail-ends together so as to convert them as nearly as possible into a continuous beam. One method was to widen the joint-chair to a double width, but as the rails were only fastened by a wooden wedge, this did not last long; and, when loose, the tilting action became worse with a wide chair than with a narrow one, and the joint-sleepers, though made wider, would not remedy the evil, and the rail-ends were in process of destruction under the heavy engines.

In the year 1847 Mr W. Bridges Adams applied a remedy, by moving the joint-chair away from the joint 3 inches on one side, and placing a second chair at an equal distance on the other side. The joint was thus suspended between the two chairs, and keys of iron called *fishes*, fitting the side channels of the rails, being driven in on each side between the chairs and rails, it was designed to convert the rails into a continuous beam, without any loose movement at the joints. (See fig. 20.) In subsequent modifications, the fishes were, and continue to be, bolted to and through the rails, the sleepers being placed considerably apart, and the joint suspended between them, constituting the famous "fish-joint." (See figs. 21, 22, and 23.) There is a difficulty in keeping the bolts tight on this plan.

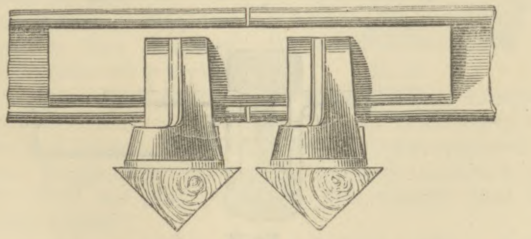

Fig. 20.
The original Fish-Joint, by W. Bridges Adams.

A more perfect joint has recently been introduced, called the bracket-joint. The rails are supported direct on the wooden sleeper, and a pair of brackets of angle iron are bolted to and through the rails, and also bolted or spiked down to the sleeper. In this mode there is no loose movement, and an economical as well as efficient arrangement is effected, the lower table of the rail being saved from all damage; the base is widened, and the rail is lowered. The same plan is applicable to intermediate chairs. (See fig. 24.)

Sleepers.—About the year 1848 general attention was called to the destruction and rotting of wooden sleepers. The contract system and improper inspection had resulted in many lines being laid with woody fibre, scarcely deserving the name of timber. Many such sleepers were like a mere pith before they were laid down, and they rapidly rotted. But there are abundant instances where good timber has been on the ground as sleepers from twelve to fifteen years without rotting. The creosoting system has also the effect of making inferior wood chemically durable.

Permanent Way.

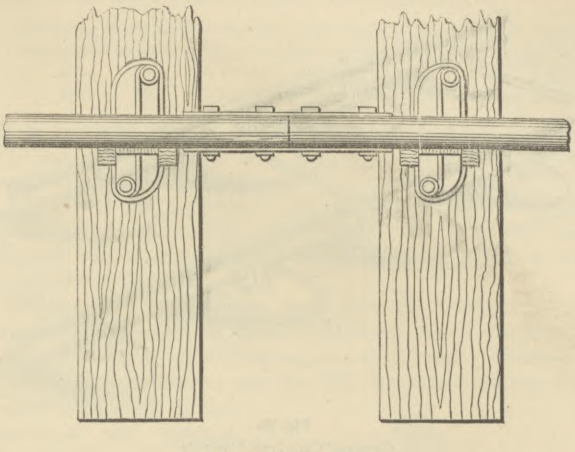

Fig. 21.
The Modern Fish-Joint (Plan).

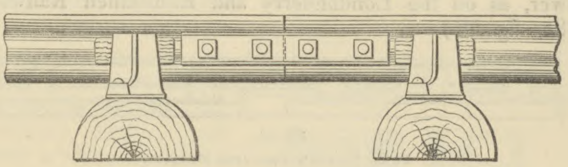

Fig. 22.
The Modern Fish-Joint (Elevation).

But the destruction of the sleeper is chiefly mechanical,—it is crushed and split by the detail bending of rails laid on longitudinals, and on the chair system by the driving of the chairs below the surface of the wood by blows. For this reason, chairs have grown in weight from 15 lb. to 42 lb. apiece, in order to increase the surface bearing on the timber.

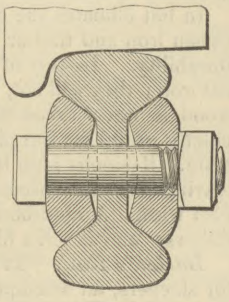

Fig. 23.
Section of the Fish-Joint.

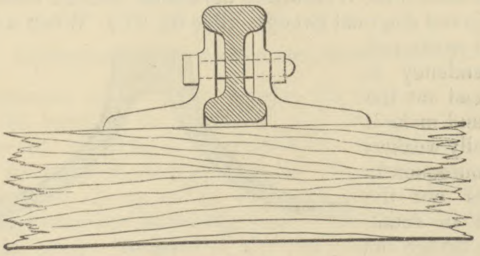

Fig. 24.
The Bracket-Joint.

On considering the question commercially, the materials of a railway should be governed by the locality. Where timber and labour can be had very cheap, it might be worth while to replace the sleepers every year. Where timber and labour are dear, iron is preferable. Cast-iron has been frequently used for sleepers, but the process has been in result little more than applying the usual cast chairs with extended bases of various kinds, and removing the wooden sleepers. Mr Greaves employs a bowl of cast-iron, with the chair cast upon it. (Fig. 25.) The South-Eastern went largely into it, on the plan of Mr P. W. Barlow, holding the rails between separate chair-heads like a vice. But, to keep down price, the rails were lightened, and the sleepers were cast thin and brittle like biscuit: they did not answer expectations, as the rails broke for want of continuous bearing.

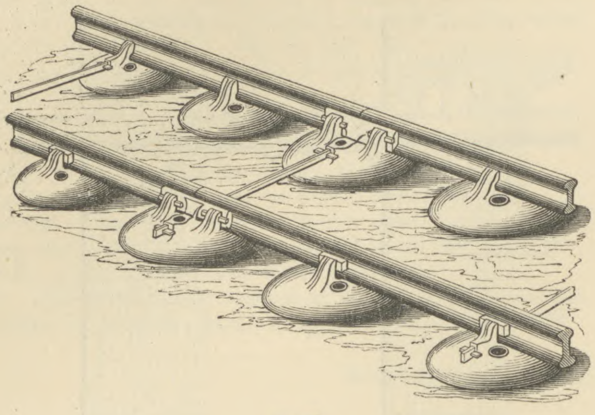

Fig. 25.
Greaves' Cast-Iron Sleepers.

On lines of small traffic and light loads the plan does answer, as on the Londonderry and Enniskillen Railway. (See fig. 26.)

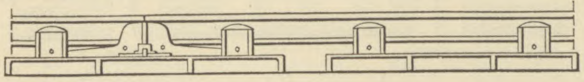

Fig. 26.
P. W. Barlow's Cast-Iron Sleepers.

Every form of cast-iron sleeper involving the chair construction is defective on account of irregular shape. The chair itself is much of a block shape, and not liable to warp; but when extended into a broad sleeper, it is very awkward to deal with.

In hot climates the question has yet to be decided between iron and timber on another account than mechanical durability. Insects of various kinds eat wood, but do not eat iron; they will not, it appears, eat creosoted wood. But wood is never creosoted all through; in fact, creosote is chiefly useful for soft pine and inferior woods containing no resin. Resinous pine is as durable as creosoted pine. But leaving out the insects, there are heat and moisture to deal with. A monsoon rain soaks the timber; a hot sun follows; and it splits like green timber similarly exposed.

Barlow's Rail.—At the time of the advent of cast-iron for sleepers, an attempt was made to use wrought iron, both in the form of sleepers, as a substitute for wood, and also in a form of rail bearing direct on the ballast without any sleepers, known as the saddle-back or Barlow rail. A bridge rail (fig. 8) consists of two vertical sides connected at the top, and the bottom spread into horizontal flanges. In the saddle-back these vertical and horizontal lines are connected into curved diagonal sweeps. (See fig. 27.) When a load is placed on this rail, the tendency is to spread out the base, and make it vertically weaker; it consequently crushes out the ballast in detail, as the bridge rail crushes into the timber. The mode of connecting the rail-ends together is by a saddle inserted in the hollow, through the lower edges of which rivets are passed. The strength of the joint, therefore, is little else than that of a piece of boiler-plate, and there is no provision for expansion and contraction under change of temperature. This rail fails in the essential conditions of a permanent way, and has not answered unless on lines of slow speed, and infrequent and light traffic. Curiously enough, as is not uncommon in inventions, it is largely applied for a very different purpose, to the wales of iron colliers as a fender against wharves.

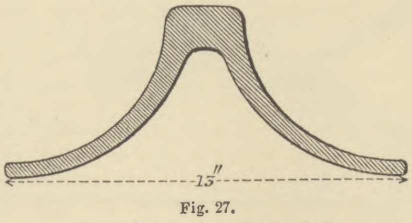

Fig. 27.
The Saddle-Back, or Barlow Rail.

W. B. Adams' Suspended Girder Rail.—In all the systems of permanent way hitherto described, the rails have been insistent, or supported on their base. They have consequently been limited in depth to insure stability against the lateral action of passing loads; and their capacity for resisting deflection has been correspondingly limited. The proper course to obtain a non-deflecting surface is to increase the depth of the rail, making it also a practically continuous beam, as strong at the joints as at the intermediate portions. Thoroughly to combine the conditions of stability and stiffness, hitherto but imperfectly accomplished, Mr Adams increases the rail to the necessary depth, and suspends it by the upper table, instead of supporting it on the base. The weight of the rail does not increase in the same proportion as the depth, if properly applied; whereas the stiffness increases in a high ratio. If, for example, with the same weight of material, having the same form and area of section, the depth be doubled, the stiffness would be increased four times; and if also the weight be doubled, the stiffness would be increased eight times. In the ordinary mode of supporting a rail on its base, the vertical web is from three-fourths to seven-eighths of an inch in thickness, to prevent it from bending under the weight of trains; and the deeper the rail, the thicker should be the web. But if suspended by the head, little more thickness is required than to prevent the top and bottom from separating. Thus an ordinary 75 lb. rail, 5 inches in depth, may be increased to 7 inches deep, and the vertical stiffness to resist deflection doubled, without an increase of metal. (See fig. 28.)

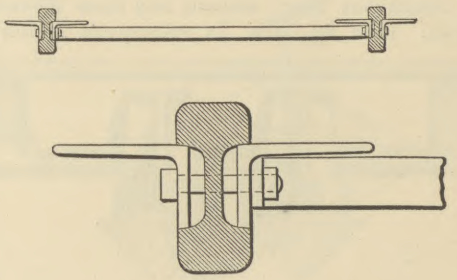

Fig. 28.
W. B. Adams' Suspended Girder-Rail, with Angle-iron Brackets.

By the suspension of the rail by the head, the bearing surface on the ballast is approximated to the bearing surface on the rail, and stability is insured independently of the depth of the rail; indeed the general stability is increased by extra depth of rail, as the rail descends into the ballast as a keel, and fixes itself there. The rail is 7 inches deep, and it is suspended by two continuous angle-brackets bolted in the side channels, affording a bearing surface within 2½ inches of the tread of the wheels. The bolts are applied at intervals of from 2 to 3 feet; all the joints intersect each other; so that wherever a joint occurs, either in the rail or the angle-bracket, two solids are in connection with it. Thus there is great stiffness laterally, as well as vertically, in the system. The total width may vary from 9 inches to 14, representing the largest amounts of bearing surface of the Great Western, and the smallest on the cross-sleeper system. The perfect distribution of the load over a large space by the vertical stiffness of the rail, will of course, with the continuous bearing, render a given surface more available than the same amount of surface on the discontinuous system. The guage of way is adjusted by tie-bars. The system is simple, consisting of only four types or parts,—the rail, the angle-iron, the tie-

Permanent Way.

bar, and the bolt; and the lower table of the rail is not exposed to the injury incurred by bearing on metal chairs, which wear into the lower sides of rails supported by them, and unfit them for reversal when the upper table is worn. This system, in wrought-iron, has been satisfactorily tested on two metropolitan railways; and is being used for railways in India, being portable, easily put together, and durable in a timber-destroying climate.

The principle of suspension by the upper table is applicable also with timber bearers, bolted in the side channels of the rail, the joints being made with angle-brackets 18 inches long, bolted to a cross sleeper at each joint. The timber may be 5 inches by 4 inches in scantling, keyed to the rails with flat bar-iron at intervals of 3 feet, making up a total width of 10½ inches. (See fig. 29.) When the upper table is worn, reversal is simply performed, the joint-bolt being taken out, and the rail and timbers together turned end for end, or upside down, to present a new surface for wear, without disuniting the timbers from the rail. The entire horizontal area is available for bearing surface on the ballast; in the cross-sleeper system only three-fourths is available. The horizontal bearing of the rail on the timbers is equivalent to 2 inches continuous width, or 504 square inches for a 21-feet rail. The timber suspension has been applied to the ordinary rails on the hardest-worked metropolitan railway with but an inch of bearing of the rail on the side timbers (see fig. 30); and after fifteen months' work, it was found that there had been absolutely no movement nor abrasion between the rails and the timbers; they had become, in fact, cemented together, contrasting forcibly with the bearing of a rail in an ordinary chair, and illustrating the essential difference between firm contact and loose contact of parts subjected to blows. It appears by this that the suspended system is upwards of 25 per cent. per single mile cheaper than the ordinary system.

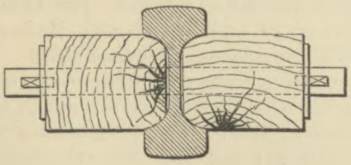

Fig. 29.
Adams' Suspended Rail, with Timber Bearers.

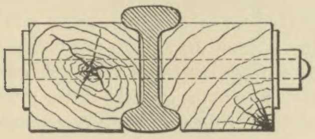

Fig. 30.
Ordinary Rail, with Timber Bearers.

In applying cast-iron for the bearing surface of the suspended rail, the disadvantage is, that on account of its inherent brittleness, it cannot, without great surplus weight, be used in long and continuous lengths; but with a stiff rail, using the iron in short lengths, so applied that it cannot get loose, but merely serving as a bearing, a good line may be made. (See fig. 31.) The cast brackets are bolted to the rail by flat iron key-bolts passing through from side to side. The brackets are each 2 feet in length, and when bolted to the rail make up a width of 12 inches. If pitched at 3 feet apart, leaving spaces of 1 foot between them, they would give a bearing equivalent to 9 inches continuous width through the whole length on the ballast. The rail is shown 6 inches deep, and 65 lb. per yard. Should the bolts slacken at all, the pressure would still be exerted against the head of the rail, and would prevent loose movements. If the brackets be laid continuously, they give a 12-inch continuous bearing.

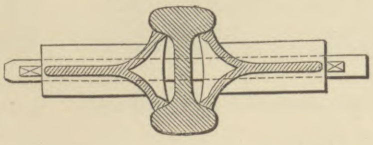

Fig. 31.
Suspended Rail, with Cast-iron Brackets.

The following are the relative costs of the ordinary cross-sleeper system, with 70 lb. rails, in 21-feet lengths, fished at the joints, and sleepers at 3 feet intervals, compared with the three varieties of the suspended system, with 65 lb. rails, and with continuous bearing:—

Earth-works.

Ordinary cross-sleeper system, per single mile run	L.1618
Suspended system, with wrought-iron bearers	1758
Do. do. on timber bearers	1200
Do. do. on cast-iron bearers	1431

It is assumed in this comparison that a 65 lb. rail on the suspended system is as efficient as a 70 lb. rail on cross sleepers.

There is an additional element of saving in the reduced depth of ballast required for carrying the suspended rail, compared with other systems, which is not reckoned in the comparison.

Ashcroft's Chair.—This chair may be accepted as the most recent exhibition of the combined use of timber and cast-iron for the immediate support of the rail. Chairs are cast in the form shown (see fig. 32), the jaws inclining outward and upward. Wood packings are pressed into the chair, of which the jaws are serrated to seize the wood; the wood cushions and suspends the rail in the chair. The chairs are of course heavier than ordinary chairs; and with a piece of oak on each side, they give a total bearing area to the rail of 18 inches in each chair. This on a 21-feet length rail will be equivalent to 126 inches, which might serve with a non-deflecting rail. But inasmuch as a chair of 48 inches area is found to drive into the sleeper, it seems scarcely possible that 18 inches inside the chair should resist the weight. If the rail springs, the whole must work loose in the same mode as the ordinary wood keys.

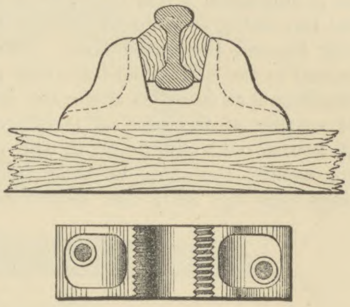

Fig. 32.
Ashcroft's Chair.

The chief defect in our permanent way, indicated by the noise familiar to travellers, is the number of blows or knocks arising from want of fit in the parts. With our present experience there is neither difficulty nor excessive cost in making a fit with either; and where wood can be applied as sleepers, it is commonly the cheapest. The principle of suspension in its application supplies a complete and general solution of the problem of a really "permanent" way; and though it is of comparatively recent origin, the method of laying rails by suspension must, in one form or another, supersede all the ordinary modes of supporting them by props. Stable equilibrium is undeniably preferable to unstable equilibrium.

EARTHWORKS—CUTTINGS AND EMBANKMENTS.

Engineers endeavour so to plan the works of a railway that the earth to be excavated shall be equal to the embankment, effecting a re-distribution of material rather than its removal, and arriving at the desired result by the simplest means and in the most economical manner. A straight and horizontal line is the standard of perfection; and the proper business of the engineer in laying out a railway is to harmonize the engineering and the financial conditions of the problem so as to yield the greatest return for the money expended; and that whilst the railway may be neither quite straight nor quite level, it should not be excessively costly in construction, in order to be free from severe curves and gradients, nor excessively cheap, making a heavy line, and incurring heavy working expenses.

The earthwork is the foundation and support of the whole superstructure, and, as such, must be uniformly firm, and carefully considered with respect to material, preparation, form, and drainage:—of liberal width, easy slopes, ample ballast, thorough drainage. (See fig. 33.) The figure shows in section the ordinary formation of a cutting in earth; the formation-level *aa*, 33 feet wide, is bounded by the side-drains *bb*, beyond which the slopes ascend to the natural surface at the rate of 1 foot rise to 2 feet level, or shortly 2 to 1. Upon the formation-level the ballast, *cc*, is deposited, 2 feet in depth, and about 23 feet wide at the top, being so wide, in fact, as to extend 4 feet on each side beyond the outer rails. The sleepers and chairs are buried in the ballast, and the rails partially also; the latter standing 2 to 3 inches above the ballast. The total width of cutting at the base *dd* is 42 feet; at the top it varies of course with the depth of the cutting. Embankments are usually the same in their ruling dimensions as cuttings (see fig. 34); the formation-level being, as in the other, 33 feet wide, sloping down to the natural surface. These dimensions are for narrow-guage lines. For the broad guage the cuttings are 38 feet wide, and the embankments are 43 feet wide at the level of forming. In both guages a clear space, 6 feet wide, is allowed between two lines of rails; and the total width over the up and down lines is over 16 feet on the narrow guage, and about 21 feet on the broad.

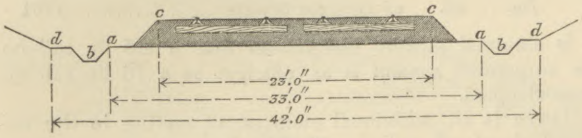

Fig. 33.
Section of a Cutting, with Ballast and Rails.

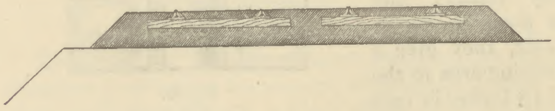

Fig. 34.
Section of an Embankment.

The slopes of cuttings vary according to stratification, soil, direction of the vein, moisture. In gravel, sand, or common earth, the slopes rise 1 foot for 1 to 1½ or 2 feet of base; in solid rock the slopes are nearly vertical. Cuttings are as deep as from 50 to 100 feet below the surface, and embankments similarly as high above. The London and Birmingham Railway had upwards of 12 millions cubic yards of excavation, and 10½ millions of excavation in the original estimates, or above 200,000 cubic yards of earthwork per mile. The heaviest cutting on the line is at Tring, 2½ miles long, averaging 40 feet deep, the greatest depth being 60 feet. The New Cross cutting of the South-Eastern Railway is 2 miles long, and is for some distance 75 to 80 feet deep. The Winchburgh cutting on the Edinburgh and Glasgow Railway, is 4 miles long, and from 25 to 60 feet deep, through solid rock; it is succeeded by an embankment 1½ miles long and 60 feet high, followed in immediate succession by a stone viaduct half a mile long and 80 feet high. The Olive Mount cutting of the Liverpool and Manchester Railway is 2 miles long, and, at some places, 100 feet deep. In the formation of the famous roadway over Chat Moss, on the same line, 670,000 yards of peat were consumed in forming 277,000 yards of embankment. Large quantities of embankment sunk in the moss; and when the engineer, after a month's vigorous operations, had made up his estimates, the apparent work done was often less than at the beginning of the month. Chat Moss was 4½ miles across. Cattle could not stand on it, and a piece of iron would sink in it. The railway was made to float on the bog; and it must be allowed that this situation, unprecedented at the time, afforded an unequivocal proof of that admirable self-reliance which never contemplated failure.

TUNNELS.

In passing through the consecutive cuttings of a railway, travellers usually consider that those through rock must have been desperate undertakings, very much more expensive than cuttings through clay. Their relative costs do not, however, greatly differ; for, not only does the vertical rock-cutting require less excavation than the wide yawning earth-cutting of the same depth, with extended slopes, but when it is executed, the rock cutting is not liable to the expensive slips which sometimes overtake the other.

In determining whether the line should proceed by cutting or by tunnelling, it is usual to prefer the former for any depth less than 60 feet; for greater depths it is usually cheaper to tunnel. The tunnel (see fig. 35) under Callander ridge, near Falkirk station, on the Edinburgh and Glasgow Railway, is a fair average representation of tunnels as usually constructed. It is lined with brick, 18 inches thick, founded on stone footings of greater breadth, in order to throw the load securely upon the subsoil, as shown in the transverse section. The sides and roof of the tunnel are curved from footing to footing, so as effectually to resist the inevitable external pressure of the earth, to a span of 26 feet in width, and a height of 22 feet. The sectional view shows also the centering or timber framing employed in the building of the tunnel, which was so braced diagonally and transversely as to resist the unavoidable inequalities of pressure without alteration of form whilst the arch was in course of construction. Externally, the entrances are built of stone, and the flank walls are three feet in thickness, with counterforts at intervals. This tunnel is not straight, but is formed on a curve of one mile radius; and it is 830 yards, or nearly half a mile in length.

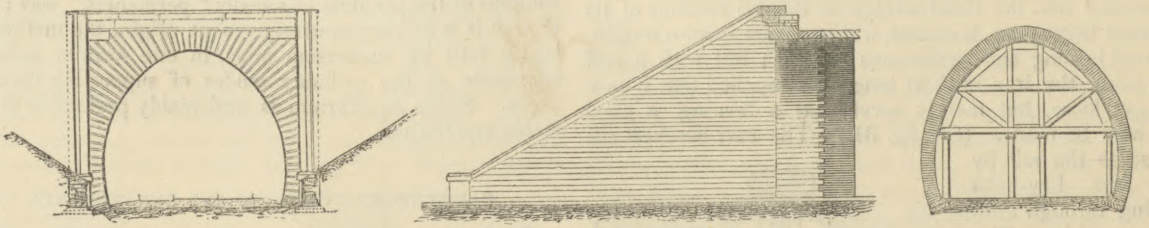

Fig. 35.
Tunnel under Callander Ridge, on the Edinburgh and Glasgow Railway.

The history of the Kilsby tunnel, on the London and Birmingham (now the London and North-Western) Railway, is interesting. It is known that the engineer's deliberate opinion was, that the line ought to pass through the town of Northampton,—an arrangement which would of course have vastly enhanced the commercial importance of the town. The inhabitants, however, urged and excited by men of influence and education, opposed the project, and succeeded in distorting the line, *via* the Kilsby tunnel,—which, if the projected plan had been adopted, would not have been required,—to a point five miles off. It was not then considered that railways could supersede mail and stage coaches; they were looked upon as, and declared to be, "but smoky substitutes for canals." The tunnel is driven 160 feet below the surface; it is 2398 yards in length, or about 1 mile and 3 furlongs, and is 30 feet in width, and 30 feet high, constructed with two wide air-shafts 60 feet in diameter, not only to give air and ventilation, but to admit light enough to enable the engine-driver, in passing through it with a train, to see the rails from end to end. The construction of the tunnel was let for the sum of L.99,000, or upwards of L.40 per yard run; but owing chiefly to the existence of unseen quicksands, undetected until they were broken into in the progress of the works, and which incurred a vast increase of expenditure, the tunnel is stated to have actually cost nearly L.300,000, or L.125 per yard lineal.

The famous Box tunnel, on the Great Western Railway, between Bath and Chippenham, was another difficult and expensive work. The tunnel is about 70 feet below the surface; it is 3123 yards in length, or rather more than 1¾ miles; the width is 30 feet, and the height is 25 feet. Where bricked, the sides are constructed of seven rings, and the arch of six rings of brick, and there is an invert of four rings. There are eleven air-shafts to this tunnel, generally 25 feet in diameter.

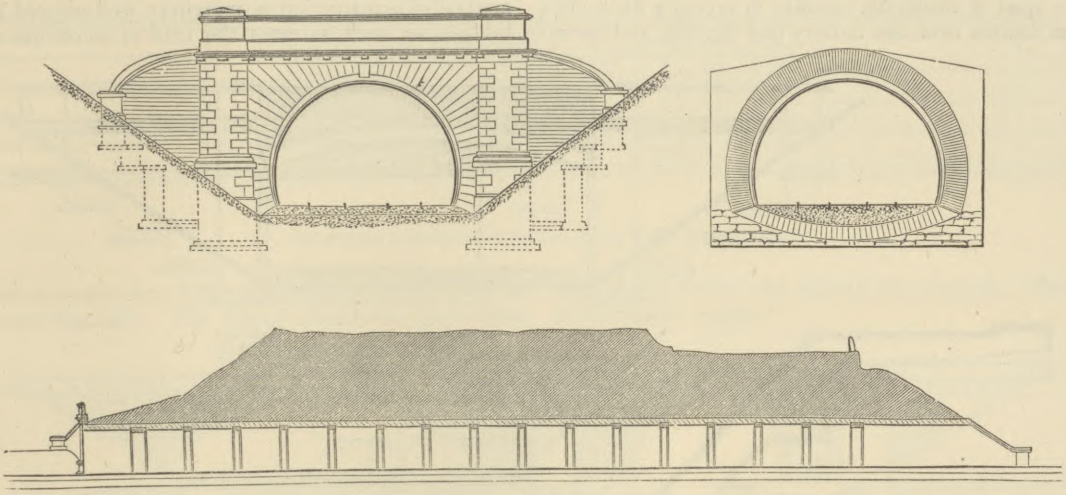

Fig. 36.
Tunnel under the Mound, at Edinburgh, on the Edinburgh and Glasgow Railway.

The tunnel under the Mound at Edinburgh (see fig. 36), on the Edinburgh and Glasgow Railway, supplies an excellent illustration of tunnels formed with inverts,—that is to say, inverted arches built under the rails. The first figure represents the elevation of the eastern entrance to the tunnel, which is architecturally good; the second figure is a transverse section, showing the truly circular arch of the tunnel, 28 feet in diameter, and 20 feet high above the rails, built of brick 3 feet thick, stiffened with counterforts externally, and with ribs of masonry internally, founded on a solid bed of mason-work, with an inverted arch to distribute the weight. The third figure is a longitudinal section of the tunnel, showing the stiffening-ribs, with a transverse section of the Mound standing 42 feet above the crown of the arch. The Mound,—or "Earthen Mound," as it is properly called,—is an accumulation of loose earth and rubbish excavated for the foundation of the houses in the New Town of Edinburgh, deposited in the valley which separates the Old Town from the New, on a boggy soil. The soil and the deposit were thus both of them unstable; and hence the necessity for the invert arch, on which the tunnel may be conceived to float.

The Shakspeare tunnel, or, more correctly, double tunnel, driven through the Shakspeare Cliff, near Dover, on the South-Eastern Railway, was peculiarly constructed, and under peculiar circumstances. It is, in fact, two narrow tunnels, carrying each one line of rails (see fig. 37), 12 feet wide, and 30 feet in extreme height, through the chalk, separated by a solid pier or wall of chalk 10 feet thick. The chalk is of variable quality, and the greater part of the tunnel is lined with brick, strengthened by counterforts at 12 feet intervals, which carry the weight of doubtful beds of chalk. The tunnel is 1430 yards, or upwards of three-quarters of a mile in length, rising westward, with an inclination of 1 in 264. The tunnel being within a short distance from the face of the cliff, the material excavated was discharged through galleries about 400 feet long, driven in from the face of the cliff, into the sea; the first operation being to run a bench or roadway along the face of the cliff. There are seven vertical shafts from the surface, averaging 180 feet deep.

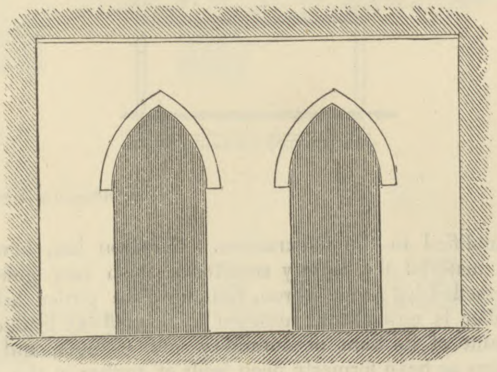

Fig. 37.
The Shakspeare Tunnel on the South-Eastern Railway.

There are about 70 miles of railway tunnelling in Great Britain, or 1 mile of tunnel for 130 miles of railway. The cost of tunnelling has averaged L.102 per mile. The longest tunnel is the Woodhead, at the summit of the

Bridges and Viaducts.

Manchester, Sheffield, and Lincolnshire Railway, being 3 miles 60 feet long.

BRIDGES AND VIADUCTS.

There are very few level crossings on English railways, —that is, the crossing of one railway with another, or with a common road, at the same level. The chances of accidents are so great as to have demanded, in general, the construction of bridges over or under the railway. The general appearance of an ordinary stone or brick bridge is represented by fig. 38, showing in elevation a bridge over or under the railway. The minimum height of a bridge over the railway is ruled by the elevation necessary to clear the top of the chimney of the locomotive. An excellent method of carrying roads over railways, where the height is limited and the span is moderate, consists in erecting flat-arched cast-iron beams over the railway (see fig. 39), and throwing brick arches of small span between the beams upon their lower flanges, to carry the roadway. Thus the vertical depth from the soffit or crown of the main arch to the roadway above, may but very little exceed the depth of the beam, which is apparent in the sectional views. This method of construction is, moreover, well adapted for skew-bridges, or such as cross the road at an oblique angle, as exemplified in the illustrations. Cast-iron has, however, as a material for railway structures, been very generally superseded by wrought-iron, forming plate girder bridges. Timber is now almost unheard of for railway bridges, on account of its want of durability and stiffness, and such bridges as have formerly been built of timber in this country are being rebuilt of stone, brick, or plate-iron. Nevertheless it may be proper to place on record the best and most successful form of timber-bridge structure for carrying a railway, introduced by Mr John Miller, C.E., in the works of the North British Railway. The Linton bridge on that line (see fig. 40) is a masterpiece of construction, the timber being so disposed as to combine a perfectly stiff, unyielding platform with lightness and economy of material and workmanship.

Bridges and Viaducts.

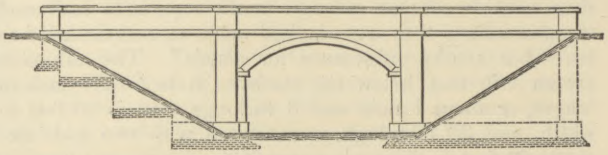

Fig. 38.

Ordinary Bridge over or under a Railway. The left-hand side is for a Cutting, and a Bridge *over* the Railway; the right-hand side is for an Embankment and a Bridge *under* the Railway; the difference is in the foundations.

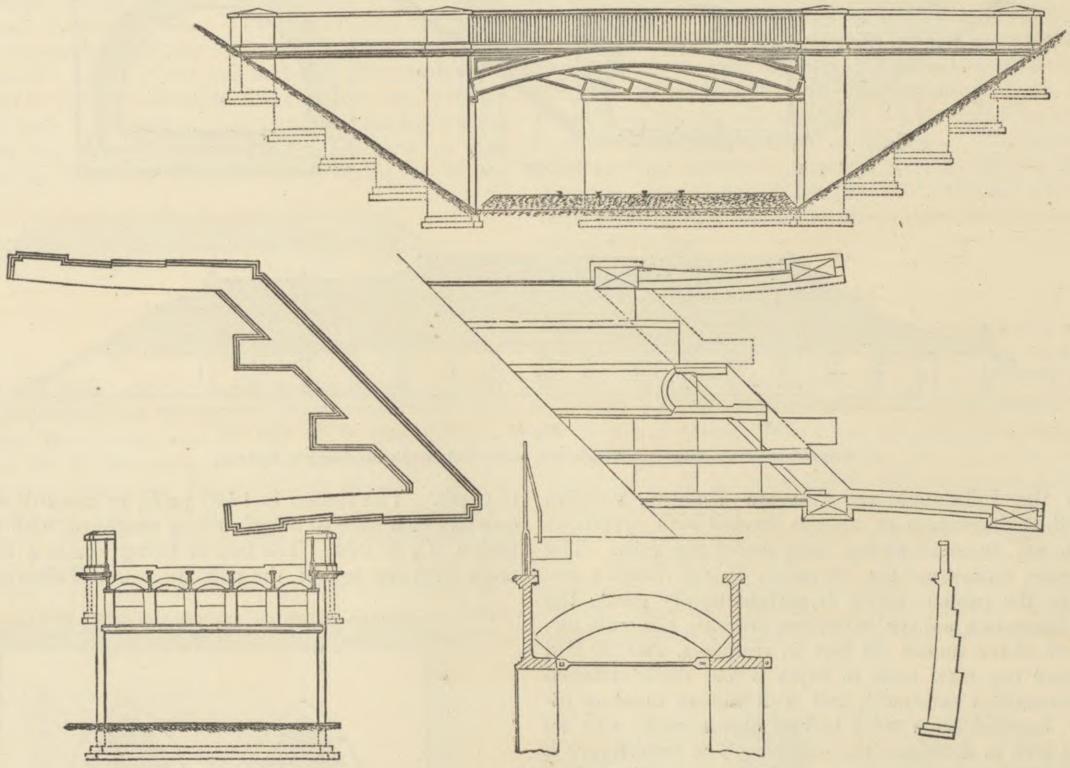

Fig. 39.

Skew Bridge, constructed with Flat-arched Cast-Iron Beams.

A bridge or viaduct, of a diversified character, was erected by Mr Miller across the Union Canal, near Falkirk, on the Edinburgh and Glasgow Railway. (See fig. 41.) The flat arch, crossing the canal to the left, has a span of 130 feet, and a rise of only 24 feet 6 inches. The lateral thrust of this arch is immense; and the precautions of the engineer to provide the necessary resistance have been commensurate, having constructed very formidable and weighty counterforts on the extreme left of the arch, with inverted arches above to distribute the thrust, as shown in the sections. The peculiar form of centering, or timber frame on which the arch was built, is also to be remarked. It receives no intermediate support from the ground, but rests exclusively upon the piers, contrasting strongly with the centering of the neighbouring arch, which, though the arch is nearly semicircular, and has only 63 feet of span (less than half that of the flat arch), is supported at two intermediate points directly from the ground. The difficulties here encountered arose not from physical causes, but from the ill-natured jealousy of the Union Canal Company, whose vested rights of traffic between the two terminal cities were

Bridges and Viaducts.

supposed to be infringed by the railway company. They would not allow the use of their ground for supporting the centering of the arch over their canal, and drove the railway company to carry it entirely from the piers. The intermediate piers were built, as shown, on timber piles, as the ground was soft. The Union Canal now pays better than it did before the railway was opened. The viaduct is 440 feet in length.

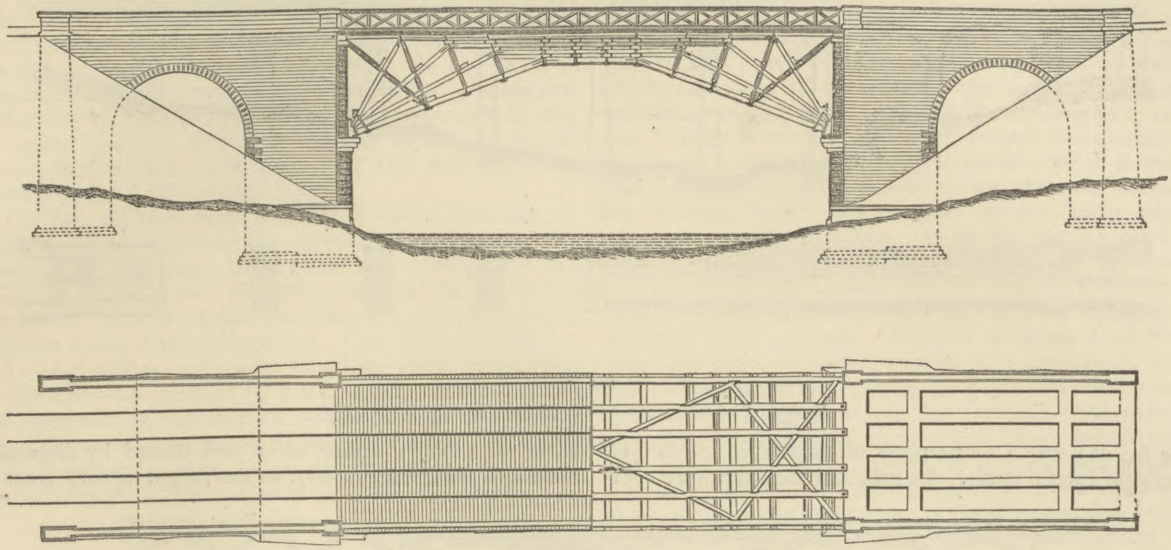

Fig. 40.
Linton Bridge, of Stone and Timber, on the North British Railway.

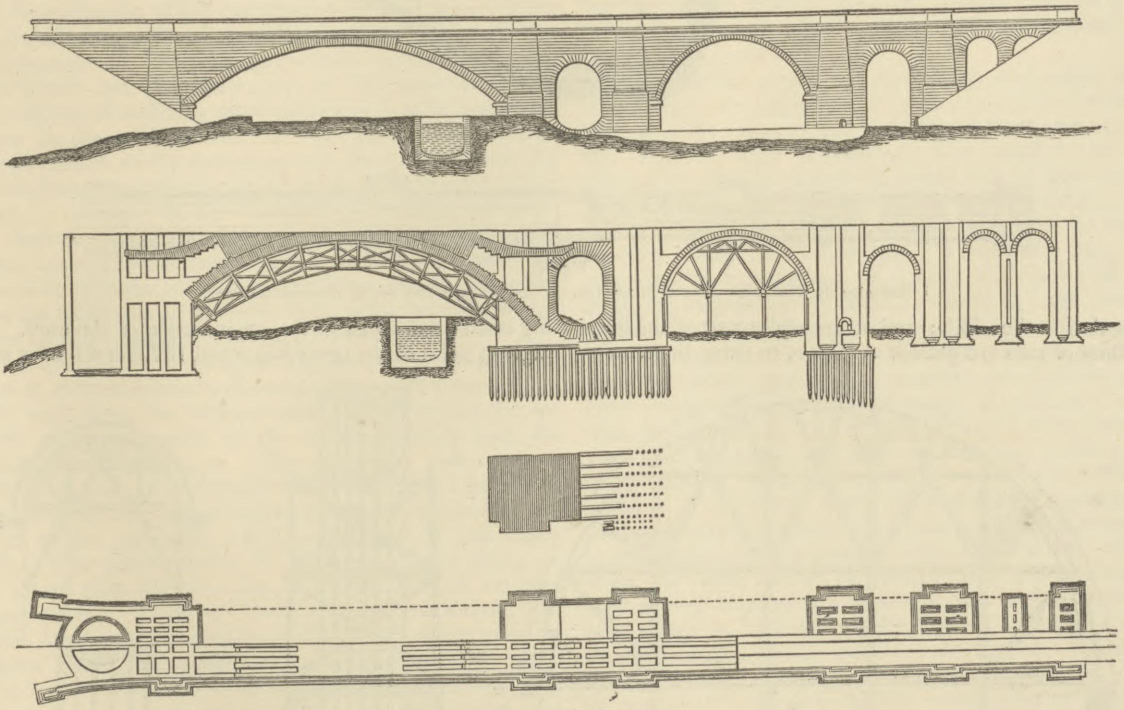

Fig. 41.
Viaduct over the Union Canal, near Falkirk, on the Edinburgh and Glasgow Railway.

There are several extensive viaducts on the Edinburgh and Glasgow Railway, the principal of which is over the Almond water. It is built of stone, and consists of thirty-six segmental arches, each of 75 feet span, and with piers 7 feet in thickness, at an average height of 50 feet; the whole length being 720 yards, not much less than half a mile. The Redburn viaduct (see fig. 42), consists of eight segmental arches, 50 feet span, and 16 feet 8 inches rise, on piers 7 feet thick at the upper part; the arches are 2 feet thick, and have a total width of 28 feet. The bed of the river is 90 feet below the level of the rails.

One of the most imposing structures of this class, forming part of the Glasgow and South-Western Railway, is the Ballochmyle viaduct over the River Ayr, built of stone, which spans the river by a semicircular arch of 180 feet, founded on rock,—the largest span of railway masonry in this country, or probably elsewhere, with six smaller arches of 50 feet span. (See fig. 43.) The arch-stones of the central arch are 4 feet 6 inches broad. The centering of timber erected for the construction of this arch (see fig. 44) was a masterpiece of carpentry, and is well worthy of careful study. Its principal members were composed of 14-inch square balks, well braced by diagonals, more especially transversely, as the height is very great in proportion to the width; and at the upper part of the framing, lines of rails are placed, as shown, to carry the traversing cranes employed in the construction of the arch. The highest point of the centering stood 157 feet 4 inches above the bed of the river, and the level of the rails of the viaduct stands about 167 feet high.

The Congleton viaduct, on the Manchester and Birmingham Railway, is perhaps the longest in England; it is of stone, 1026 yards, or more than half a mile in length, and 106 feet high, and it cost L.113,000, or L.113 per yard run. The Dane viaduct, on the same line, is of brick, 572 yards long and 88 feet high, and it cost L.54,000, or L.95 per yard run, having 23 arches of 63 feet span. The Avon viaduct, on the Midland Railway, is of brick, 240 yards in length, 51 feet high, with 11 arches of 50 feet span; it cost L.14,000, or L.60 per yard run. For comparison, it may be stated that the Britannia Tubular Bridge across the Menai Straits, 616 yards long, and 104 feet high, cost L.600,000, or L.98 per yard run.

On the different lines entering London there are 11 miles of brick viaducts in the approaches to termini. At Manchester and other large cities and towns there are miles of similar works, extending often as far as the eye can reach. It is estimated that there are about 55 miles of viaducts in the United Kingdom. (See Iron Bridges.)

Level crossings—of public or private roads on the level of the line—are guarded by gates, one on each side of the line, generally of considerable width, to close the railway when the crossing is opened to the public road. Each gate is provided with a red or danger signal, so that when closed on the line, the signal is visible to approaching trains.

STATIONS.

The great theatres of the operations incidental to the transfer from place to place of persons and goods, preliminary and subsequent to the transport, as well as at certain epochs in its progress, are the *stations.* Stations are either "terminal" or "intermediate." The vast buildings and their dependencies which constitute a chief terminal station of a great line of railway, consist primarily of three distinct departments:—1. The passenger station, appropriated to the embarkment and disembarkment of the passengers, and other objects of traffic, as small parcels and mails, which are carried by the same trains. 2. The goods station which is appropriated to the reception and embarkment, and the disembarkment and discharge, of goods and live stock transmitted by railway. 3. The locomotive, carriage, and waggon depots, where the engines and the carrying stock repose, are cleaned, examined, and repaired. At many intermediate stations the same arrangements, on a smaller scale, are made; in all of them there is at least accommodation for the passenger and the goods traffic.

The stations for passengers and goods are generally in different and sometimes in distant positions; the place selected for each being that which is most convenient for the approach and arrangement of the traffic to which they are respectively appropriated. The passenger station abuts on the main line, or, at termini, forms the natural terminus, at a place as near as can conveniently be obtained to the centre of the population which constitutes the passenger traffic. The goods station is approached by a siding or fork set off from the main line, at a point short of the passenger station. Thus, at Liverpool terminal station, the branch leading to the passenger depot enters the town by a tunnel beneath the streets, and terminates near the centre of the town. The branch leading to the goods station, likewise conducted by a tunnel under the town, is carried to the docks and quays, where the goods are received directly from the shipping upon the rails, and reciprocally from the rails to the shipping.

To avoid the necessity of taking locomotives into the town under such circumstances, and sometimes because the lines are conducted to the terminus by inclined planes, these terminal branches of the railways are sometimes worked by stationary engines and ropes to the point where the locomotive joins the train.

The locomotive station is placed wherever the ground may most conveniently be obtained, at or near to the terminus; in some cases it is found at a distance of 3 or 4 miles.

The selection of intermediate stations, their number, situation, and arrangement, is influenced mainly by the nature, extent, and occupation of the local population; and the first step should be to get a good map of all the places within the scope of the railway, and to mark upon it the population of each place from the last parliamentary census. There is no doubt that the greater the number of stations, the more the travelling increases; for it is found that quick and cheap transit by railway not only increases the existing traffic, but actually creates traffic where none was to be found before. In an engineering point of view, every effort should be made to secure for a terminus or other important station, and for stations generally, a position on the surface, rather than on an enbankment, or a viaduct, or in a cutting. Facilities of access in all directions from the surrounding districts, with good roads in the case of passenger traffic, and good water and railway communication for goods depots, are obviously indispensable. For safety and regularity, there should be an uninterrupted view along the line of railway, by avoiding sharp curves and a complication of over-bridges, in the vicinity of a large station. For a terminus, a slightly-ascending incline on the approaches are convenient, to aid in controlling the ingress and assisting the egress of trains; but the inclination should not exceed 1 in 300, on account of the extra labour of handling vehicles on inclines. Intermediate and junction stations should be situated on dead levels, and when a good length of level can be had, with gradients falling from it both ways, there is the greatest possible facility for working the traffic. Falling gradients towards a station of any kind are obviously objectionable; but unfortunately they cannot in all cases be avoided.

An abundant supply of good water, and ample means of drainage, are important at stations; and it is notorious that in some cases it has been found necessary to abandon stations after completion, from neglect in these particulars. There should be ample area of land to admit of the greatest possible extension of accommodation; and the erection of buildings on land adjacent to the station-grounds should be discouraged. Companies have been compelled to re-purchase, at greatly advanced cost, land originally disposed of by them as "surplus," and generally with a view to building operations. When this course is adopted, prudent managers will take care to secure, in the conveyance, power to re-purchase the freehold at original prices, with allowance for outlay in building or otherwise, by valuation. The expediency of providing new railways with the station appliances necessary for working them in a complete form, before they are opened for traffic, is a question of moment. Some have preferred opening with temporary arrangements; others have constructed permanent works adapted for the greatest extension of traffic. Of late years the latter course appears to have been the most in favour; but whether the result of good general policy, or of a desire to facilitate the closing of the capital account, does not readily appear—probably the former. It may also be due in some measure to the recently-adopted system of guaranteed contracts for the construction of works requiring their completion, with all their adjuncts. The main objections to this system appear to lie in the impossibility of deciding in all cases beforehand upon the proper sites, and the future requirements of the traffic. Errors on these points cause inconvenience in working, and lead to a waste of money, in subsequent abandonment, or in extensive alterations or amendments. Let a comprehensive plan be devised and adhered to, and only such portions be executed from time to time as are necessary for current requirements. In this way, unnecessary pressure upon the funds, when they are generally at a low ebb, may be avoided, and credit is obtained for attention to public wants by appearing gradually to yield to the public demand for accommodation. Engineers are occasionally blamed for alleged errors and oversights, which are due entirely to their inability to make others understand the whole bearing of a scheme when presented on paper. Railway officers generally should possess so much engineering and architectural knowledge as to enable them to judge of the merits of plans whilst yet only on paper; and for the same reason that the engineer should be a machinist, the manager should be an engineer. Difficulties, again, arise from the employment of architects to design and execute station-works for want of special knowledge. In railway works, the function of the architect should be limited to architectural decoration. Buildings with sundry wings, recesses, and returns, though it may be architecturally very effective, induce a marvellous amount of confusion and delay.

In laying out the approaches and station-yard of passenger stations, ample width and space should be provided, with well-defined means of ingress and egress, to facilitate the circulation of vehicles; and the setting-down pavement should be as long as possible, to admit of several carriages discharging passengers and luggage at the same time. The pavement should be wide, and sheltered from the weather by a roof, overhung beyond the kerb, or spanning the roadway; but in all cases free from columns. The position of the main buildings relative to the direction of the lines of rails is the distinguishing feature in terminal stations. When space permits, the usual course is to place them on the departure side, parallel to the platform (see fig. 45); but they are frequently placed at the end of the station, at right angles to the rails and platforms (see fig. 46). Or these two systems are combined in a third arrangement, in which the offices are placed in a fork, between two or more series of lines and platforms (see fig. 47). Of the metropolitan termini, the Great Northern (Plate I.), the Great Western, and the South-Western stations, are examples of the first class; the London Bridge stations, comprising the South-Eastern and the Brighton lines, and the Fenchurch Street station, comprising the North London, Blackwall, North Woolwich, and Tilbury lines, are examples of the second class; and the Eastern Counties, and the London

Stations.

and North-Western stations, are examples of the third class.

The first and usual class of stations commands the greatest length of setting-down pavement, ample space for booking and other offices, waiting-rooms, &c., and the shortest average distance for passengers and luggage from the offices to the outgoing trains. Nevertheless, where the traffic is various, involving the despatch of numerous trains to different points in quick succession, and necessarily with perfect regularity, the second system is the best. It admits of increase to any extent in the number of platforms for arrival and departure, with ready access to all; the rapid assortment of trains, with ready access to spare carriage-lines; and with the greatest economy of labour, the greatest facilities for the despatch and reception of trains, and the best general control over the business of the station. But where the frontage is limited, and for long traffic, there is inconvenience in the movement of luggage over a crowded platform. The third plan is probably the least commodious of the three; but it has the advantage of affording two arrival platforms, with carriage-roads alongside, the others having but one so situated. In all the classes, it may be observed, transverse lines are inserted with turn-tables, to place all the lines in compact communication, for turning on or off spare carriages, loaded horse-boxes, or carriage-trucks. Independently of the turn-tables, the lines of rail are connected by switches or points converging towards the two main lines of rail, outgoing and incoming; and thus the assortment and marshalling of trains may be effected by horse or engine power, independently of the turn-tables. Each plan of station comprises one or more large turn-tables for reversing the engine with its tender together.

The most convenient arrangement of the several offices and waiting-rooms, with all their accessories, is very important. A large exterior vestibule or hall, for those waiting for tickets, with ready communication from thence, for luggage, to the platform, clear of the stream of passengers, and a spacious well-lighted booking-office, with the greatest available length of ticket-counter, will give the greatest amount of comfort and convenience to the travelling public. The ticket-counter should be so constructed as to concentrate the business, and to reduce the number of clerks as much as possible; it should be provided with an inner glazed office, raised above the floor-level, to enable the head clerk to keep his eye upon his subordinates. The counter must be provided with numerous drawers for cash, spare tickets and books; and with a large number of ticket-tubes, arranged in series, according to the traffic requirements, each series having the means of being closed when not in use. These tubes should occupy the depth between the clerks' counter and the cash-shelf to which alone the public have access, the cash-shelf being placed breast-high, or about 4 feet from the ground. The ticket-windows ought not to be too numerous or too large, and should be legibly marked with their several distinctions. High barriers have usually been placed before each window to avoid crowding and to secure the pocket; but the recent substitution of wide tables is a decided improvement, as they permit the retention of parcels in the hand, and more effectually expose the pickpocket to detection. The separation of classes, before reaching the ticket-counter, is desirable under some circumstances; but offers many difficulties in arrangement, and increases the labour within the counter. Where the proportion of second and third class traffic is large, there can be no doubt as to the propriety of keeping it distinct, even at the risk of some additional outlay in duplicate conveniences of all kinds. After booking, it is the custom in this country to allow the passengers and their friends to wander almost indiscriminately over the company's premises,—much to the detriment of the convenient working of the traffic. It is a question whether it might not be desirable to adopt the continental system, and to provide large halls or saloons for each class, communicating with the booking-office and platforms, with a view to confine the passengers until a few minutes before the time of starting each train. Restricted space in building-area seems to be the obstacle to the adoption of so great an improvement; added to which, the inherent restlessness of the English traveller in the matter of luggage and its safety might present some difficulty. This, however, could be easily met, and with advantage in many respects, by altering the luggage system, and compelling the public to book and pay for the whole of it at an office distinct from the ticket-counter, and attached to the other vestibule. All railway managers know but too well how much the irregularity of trains is due to the want of punctuality on the part of the public, and in no small degree to their requirements in the way of luggage. Much of this might be avoided, if railway companies had the power of converting a portion of the fare into a toll upon luggage, combined with facilities for disposing of it upon the trains before the platforms are crowded with the passengers.

Stations.

In connection with the luggage question, reference must be made to the necessity for providing a spacious cloak or left-property room, which should be accessible from the outside of the station, be conveniently situated with respect to the arrival platforms, and be furnished with every requisite for ready stowage and sorting. If built fireproof, with an upper floor to serve as a lost-property store, additional safety and economy of space would be obtained.

The system of dividing the parcels office into two, distinguishing them as "in" and "out," or "up" and "down," does not seem desirable, as requiring more clerks and attendants than is otherwise necessary. One large, lofty, and well-lighted office, to combine the whole business, is preferable, if it can be placed centrally, so as to be readily approached from both platforms; but it is essential that there should be equally good access from the outside, with complete space for the vans and town-carts to stand under cover without impeding other traffic.

The same remarks apply to a certain extent to the position and arrangement of the telegraph offices; the main object being to give every facility to the public, without actually admitting them within the station premises, securing at the same time free communication with the platforms and offices for traffic purposes. Next in importance to the arrangement and construction of the offices are those of the platforms. The practice with regard to the height above the rails has varied considerably, the recent tendency being to raise them much higher than was usual at first. Three feet may be stated as the limit in this respect, but that height has probably been adopted as a necessary consequence of the increased width of the carriages, which prevents the use of a second step. Where there is no impediment, a mean of about 2 feet has seemed advantageous, as being sufficiently convenient for entering or leaving the carriages, and being safer for the station people, who frequently have to cross from one platform to another. Too much attention cannot be given to the necessity for obtaining the greatest possible width of platform. Where the platform is used on one side only, the width ought never to be less than 20 feet; and when both sides are required, 30 feet, or even 40 feet, should be allowed. The best mode of constructing the platform is undoubtedly with stone slabs laid hollow upon longitudinal walls, so as to admit of carrying beneath it the water and gas pipes, telegraph or signal wires, and the general drainage, with free access to each. Slabs of sawn slate have been used largely, and are found to be clean and quiet; but they are not to be depended upon for safety, as it is nearly impossible to obtain them thoroughly sound. There is also always a risk of lamination on the under side, which may proceed without dis-

Stations.

covery until the slab gives way suddenly under a weight of luggage or passengers. Hard Yorkshire landings are preferable, but they require rubbing on the upper surface, to avoid the accumulation of dust and dirt. Cutting out for turn-tables and openings for cross-lines of rails are frequently inevitable difficulties, which have given rise to various ingenious contrivances, as shifting-stages, draw-bridges, &c. The substitution of "traversers" for turn-tables goes far to remove one class of impediments, and the other is best met by the use of easy inclines, with crossings on the rail-level. Where the platforms do not exceed 2 feet in height, and the surface is smooth, gradients of 1 in 10 are not too steep for luggage barrows, nor are they dangerous in a crowd. The sorting of the different classes of passengers preparatory to entering the carriages is sometimes practised by means of barrier enclosures on the platform, as on the Greenwich Railway; but this is practicable only in cases where the trains are always uniform in length and arrangement. When the nature of the traffic renders it necessary, and time can be spared, the examination of the tickets before admission to the carriages, or before the starting of the train, is a more effective and simple precaution. Many serious accidents having arisen from carelessness in getting in and out of the trains while in motion at the platforms, attempts have been made by the companies, urged by the Board of Trade, to reduce the chance of casualty by some kind of barricade along the edge of the platforms. The danger of placing fixtures so near the sides of the carriages as would be necessary to obtain the desired result, seems to have hitherto prevented the adoption of any plan calculated to meet the case; but it may be worth consideration whether a system of rising barriers, counterpoised and guided from below, might not be contrived so as to secure safety, and to some extent to answer the same purpose as would be gained by separate waiting-saloons on the continental plan.

The greatest advance in station-works during the last few years has been the roofing over, in one span, of the lines and platforms, the main object being to do away with intermediate supports of every kind. That columns or pillars in a station are objectionable, seems to be agreed upon on all hands; but where two or more spans can be so arranged as to bring the columns in the centre of wide platforms, the great extra expense of large spans may be saved, and with some attendant advantages. Whatever may be the spans adopted, every effort should be made to obtain height, light, and ventilation. Too large a proportion of glass in skylights is to be avoided, as it is apt to render the heat in summer so great as to endanger the health of the men employed, and to injure the rolling stock beneath, to say nothing of the expense of continual repairs, and the difficulty of preventing leakage and condensation. Durability is of course the great desideratum; hence iron and slate will naturally form the chief materials of the structure. It is impossible, however, to avoid the use of timber to a large extent, particularly for the sash-bars for the skylights and the boarding for the slates. Iron sash-bars, though largely used, are not satisfactory in practice, as the effect upon them of changes in temperature is so great as to render it impossible to keep the glass water-tight. The slating is sometimes attempted on iron battens, without the intervention of boarding; but the unfinished effect below is so bad, and the deterioration of the battens so rapid, that there is nothing to recommend such a mode of construction. When boards are used to carry the slates, they should be laid horizontally, and not diagonally or vertically, with a view to discover readily through the droppings from the joints the position of any leaks in the slating. Louvre ventilators, from their exposed position on the summit of the roofs, should be made moveable, with the means of closing them at pleasure, as has been done with those at the Crystal Palace. Without such a precaution, there will either be defective ventilation or continual annoyance from the driving in of rain or snow. The use of galvanized sheet-iron, whether corrugated or flat, is not to be recommended as a covering material in or near a large town, as it will be found to perish rapidly, either through the galvanic action of the metallic compound, or from the chemical effect of the sulphurous fumes of coke and coal, when largely consumed in the immediate vicinity. That material may, however, be advantageously used in the country.

Stations.

The best position for the horse and carriage docks is a question not easily decided. Experience would lead to the conclusion that two sets, one for arrival and one for departure, are not absolutely essential; but if concentrated at one point it is doubtful at which end of the platforms they will work the most satisfactorily. Looking to the greater importance of time in the despatch of trains, as compared with a certain amount of delay attendant upon unloading on arrival, the balance of advantage points in favour of placing the docks at the extremity of the station-lines, where they may be so arranged as to communicate equally with both series of rails, securing at the same time ample length of siding space for spare stock. This system has been in use at the London terminus of the Brighton Railway for some years, and answers the purpose even in times of the greatest pressure; whilst at Brighton, where the plan is unavoidably reversed, outgoing trains are necessarily stopped after starting from the platform, to allow of carriage and horse boxes being attached—an arrangement obviously defective. Despatch and regularity will be found to depend not so much on the number of each kind of dock as in the perfection of the means provided for securing a constant succession of trucks, by passing off the loaded ones, and bringing in those that are empty, without allowing them to impede each other. The details of construction require attention, particularly as to the surface, which should be wood pavement for the sake of cleanliness, and to prepare horses for the floors of their boxes; also as to the means of admitting the buffers and draw-hooks without injury either to them or to the structure, the difficulty being to provide for variation in the heights of vehicles when loaded or empty, or when not uniform in build.

The correct arrangement and appropriation of the several lines of railway in a terminal station materially affect the economical and efficient working of the traffic. Circumstances will necessarily indicate a particular principle to be followed in each case, but there are a few general rules which cannot be overlooked. It is essential that every traffic-line, both in and out, should be provided with one or more spare sidings, in addition to those set apart for the break-vans, horse-boxes, and carriage-trucks, and for the locomotive department. All these lines should communicate with each other by means of points and crossings, to allow of shunting with engine-power, and to reduce to the lowest limits the number of turn-tables or their substitutes. Sharp curves are of course objectionable, and they ought never to have a radius of less than 800 feet. The use of self-acting points or switches may be assumed to be now universal, though it is believed that some managers still prefer the old eccentric or level switch, because they involve more constant attention on the part of the pointsman, and fix responsibility with greater certainty in case of casualty. The extensive use of three-throw and four-way points is sometimes objected to, as being more complicated and costly, but if they are well made and properly fixed, there is no real difficulty in working them, and siding space can frequently be so gained with much advantage. Turn-tables in a passenger-station, and especially when placed on the traffic-lines, can only be viewed as necessary evils. The wear and tear both to the rolling and to the fixed stock, the intolerable noise when passing over them and interference with the line of platform, and the waste of space between the lines of rails, are objections sufficiently obvious to condemn turn-tables where they can be dispensed with. The late Mr C. H. Wild secured some economy in width by the introduction of his three-way tables, fixed diagonally; but his plan of using inclines at the intersection of the cross-rails, to save the hammering of the passing wheels, is not approved, as it has been found injurious to the flanges of heavily-leaden vehicles, locomotives, and tenders. By far the best substitute for the turn-table yet introduced is the traverser. If well made and carefully worked, and attended to, the shifting of carriages from line to line can be performed without extra manual labour or interference either with the rails or the platforms. In cases where the edge of the platform is unavoidably indented by the position of a turn-table in the line adjoining, there is a choice of contrivances for preserving the line when the table is not in use; such as leaves folding back on hinges, circular trollies on low wheels, stages to slide or roll back above or below the platform, and sundry other plans, all of which are but so many additional sources of obstruction and expense; hence if the turn-tables can be so placed as to fall at the ends of waiting trains, the least evil seems to be to leave the platform open with barriers to prevent accidents.

The whole area of every large station ought to be paved with stones, or with Staffordshire blue bricks laid in mortar, great attention being paid to the surface drainage. Having regard to conveniences for washing carriages and general cleansing purposes, it will be found best to form the rise in the intermediate space, and the channels and gratings within or between the rails. A longitudinal timber road, with bridge-rails, will be found to give the greatest facilities for effective paving or pitching.

It is assumed that every terminus will be provided with one or more engine turn-tables according to the nature of the traffic, but it does not appear to be the general practice to construct engine-sheds as a part of the station, probably because most lines have suburban depots, which offer greater facilities for the purposes. If, however, space can be afforded, economy and convenience are obtained by placing a shed in communication with the turn-table and coke-lines large enough to contain as many engines as usually stand about during the day, or come out for working the morning trains. The lines leading to such a shed should connect directly with those of arrival and departure, and be distinct from those appropriated to the turn-table and the coke waggons; but the best arrangement of all is, to place the shed on a loop-siding connected at both ends with the main lines, so as to obtain the easiest means of access at all times. Good light and ventilation are essential points in a well-constructed engine-shed, with ample height to the roof, and width between and outside the rails. The gas-fittings should be such as to admit of examining any portion of the machinery with accuracy; and the water should be laid on with sufficient pressure to thoroughly wash out the boilers from time to time. It is not unusual to make the large water-tank for station use, do duty as a roof to the engine-shed. To this there can be no objection, provided the tank is fixed at a sufficient height to secure perfect ventilation; and this will also improve the pressure at the points of delivery. Such tanks cannot be too large, and should never hold less than one week's average consumption, to meet the chance of failure in the means of supply. Each line of rails within the shed should have engine-pits, properly drained, and contrived to admit of examining and repairing all parts of machinery from below; similiar pits should be constructed on each line outside the shed, to admit of raking out the fires or removing the clinkers, —operations which are best done in the open air. The arrangements for coking and watering are naturally connected with the turn-table and engine-shed. Large coke-sheds or stores are now generally considered unnecessary, it being found more economical to bring up the supply from the ovens or depôts as wanted, delivering direct from the waggon into the tender. For this purpose, coke sidings should be laid alongside those leading from the turn-table, with a platform intervening, on which the coke can be weighed or measured in transit. Much time is lost in watering if the cranes are not fixed in proper numbers or position; nor is sufficient attention generally paid to having them, and the service mains leading to them, of large diameter. The gain of a few minutes in filling a tender is frequently of vital importance in working the traffic to advantage.

The collection of tickets is a branch of railway business which generally involves special provision in the arrangement of a terminus. The practice of stopping the trains for this purpose at the entrance of the station is objected to by the public, but it cannot be avoided unless there is some station immediately preceding the terminus of sufficient importance to combine traffic purposes with collecting the tickets. When such is not the case, the next best course will be to utilize the time spent in collection by running the engine round from the head to the end of the train, instead of drawing it up to the platform. Every ticket platform is usually furnished with convenient offices and mess-rooms for the head collector and his men, fitted up for sorting and arranging the tickets, keeping the books, and taking their meals: attention of this kind to the comforts of the men is always highly appreciated by them.

The road for carriages-in-waiting, which adjoins the arrival-platform, should be wide enough to permit at least two ranks to stand, with passing room clear of them; and it is essential that the means of access should be distinct from that of exit, to secure a continuous stream of vehicles, and to avoid delay in turning or meeting others in an opposite direction. Protection from the weather and from cold draughts, by means of roofing and side walls, is important, where there is a good first-class traffic, because attention in a particular so apparently trivial will not unfrequently bias the owner of valuable horses in favour of one line as compared with another. The pavement should be of wood, creosoted, if the ventilation is good, and constant attention should be paid to sweeping and cleansing, without which the ammoniacal exhalations will prove injurious to the health of the men employed at the station. At the entrance to the cab road there should be a large area, sufficient to hold at least 100 cabs, as a reserve to meet the requirements of the heaviest trains, with proper conveniences of every kind, both for the men and the horses; and at the exit should be placed the cab-inspector's office for registering the departures.

Attention to the material comforts of the men employed, and particularly of those much exposed to the weather in the execution of their duties, being an important element of success in securing good and cheerful service, it is obviously politic to furnish every large station with distinct mess or waiting rooms for the engine-drivers, guards, porters, switch-men, &c. These should be spacious, well ventilated, lighted, and warmed, and be fitted with good cooking apparatus, cupboards, lockers, and tables, and be so placed as to be near the work of each class of men. Connected with the mess-rooms may be combined with advantage offices and store-rooms for the superintendents of the different departments, such as the permanent way, locomotive, and carriage superintendents, police, &c., thus giving each an opportunity of keeping an eye upon his men, and of readily communicating with one another.

Experience will dictate the necessity for constructing sundry other buildings as accessories to the effective working of a busy terminus. The lamp-room should, if possible, be detached and be fire-proof, with warm store-rooms for oil, tallow, and waste. The dressers for cleaning and trimming should be covered with polished zinc in preference to slate. The shelves or brackets for the lamps should be sufficiently extensive to hold the largest number in use, and there should be ready means for disposing of the waste and rubbish as they accumulate, to avoid all risk of fire. It is frequently found good economy to have a few small shops for the different classes of mechanics required for repairs and for odd jobs, such as smiths, gas-fitters, joiners, plumbers, &c., much time being wasted in sending men and materials to and from the general workshops of the line. Unless a large hotel is attached to the station, it will be found necessary to construct stabling for post-horses, and coach-houses for private carriages on arrival, or when waiting to go by the trains. The construction and arrangement of the closets and urinals are too important to be dismissed without brief notice. Comfort and decency will best be consulted by distributing the conveniences amongst separate buildings in various parts of the station area, and appropriating some of them to different classes of employés, distinct from those for public use. Urinals should be freely ventilated, and be paved with slate or some other non-absorbent material; the walls should be lined with glazed tiles for 7 feet or 8 feet in height, and the divisions and backs be of enamelled slate. Risers are objectionable, and quite unnecessary if the floor have a sharp incline towards the channel. Closets, whether for the passengers or for the company's men, cannot be too simple in their construction. All brass work should be avoided, or it will be stolen. The walls should be lined with glazed tiles, or be grained and varnished, to prevent the surface being defaced; a shelf should be provided in each closet for depositing parcels, and water should be turned on by the action of the door in opening and closing. In fact, a constant and abundant supply of water both to closets and urinals offers the only chance of confining within tolerable limits the annoyances necessarily connected with such structures. The importance of keeping a large station constantly swept and cleansed is too often overlooked, in consequence of the difficulty of disposing of the dirt and rubbish which so rapidly accumulate. To meet this, proper receptacles should be distributed at various points, with shoots or traps to receive from above, and means of access below for the scavengers' carts.

The details given thus far are obviously intended to apply in the main to metropolitan termini, or to those of equal importance and extent. The leading principles, however, will be found available, more or less, according to circumstances, for the arrangement and construction of terminal stations of every description. For the purposes of illustration, attention will now be drawn to the general features of small terminal stations on branch lines of railways, with the peculiarities of each, and the advantages and defects which have been met with in working them. The several parts of the stations are distinguished in the illustrations by their initials, thus:—B.O., Offices, &c.; P., Platforms; C.P., Coke Platform; W., Warehouse; C.S., Carriage-Shed; E.S., Engine-Shed; C.W., Cattle-Wharf; C.D., Carriage-Dock; G.Y., Goods-Yard; T.H., Tank-House; G.W., Goods Warehouse; L., Lodge; W.R., Waiting-Rooms; M.R., Mess-Rooms; S.B., Signal-Box.

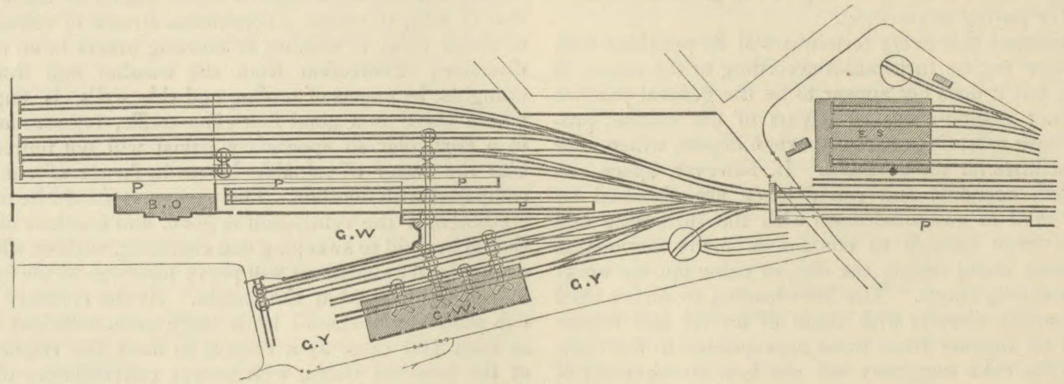

Fig. 48.

The first (fig. 48) is at the extremity of a double line of railway in an important town on the coast, and accommodates the traffic and trains of two separate companies. The peculiar shape of the land originally purchased, its position with relation to that part of the town from which the bulk of the traffic is derived, the necessity for providing means of extension, and the existence of a public street crossing on the level at the very entrance to the station, were the chief controlling elements in the original design. It will be observed that, by placing the offices and both platforms on one side, with the spare carriage lines adjoining, the frontage to the main street is economized, and left free for carrying one or more of the lines forward, as has since been done. The arrival and departure platforms are both accessible from the main lines at the same time, and are made long enough to allow one train belonging to each company to arrive and depart, or to stand one after the other; whilst an extra line, with its platform, is provided for special occasions. The great length of the station offers every facility for abundance of spare lines, which can be roofed over to any extent that may be desired at a moderate cost. The horse and carriage loading arrangements are combined with the goods and cattle lines and docks, and with the spare carriage sidings, and the whole of this department of the business is worked with great success. The approach, and the yard in front of the offices, are convenient as regards length for setting down and taking up, but are too much confined and narrow. The road should have been 50 feet wide at the least, including the footway, and the yard not less than 80 feet in width with roofing over some part of it. The position of the goods department is satisfactory, being sufficiently near to the town without any objectionable interference with the passenger station. The arrangements were not, however, so good as could be wished, having been devised under the impression that the goods traffic of two companies could be worked under joint management as easily as that of passengers. Experience has proved that separate warehouses, yards, and sidings ought to have been constructed, and that the whole accommodation should have been on a more extensive scale. The engine-sheds in duplicate, turn-table, offices, mess-rooms, shops, tanks, &c., are as well placed as the shape of the land would permit; but the table is too far from the platforms, and involves some loss of time, and the employment of extra police, to secure safety with so much crossing of the main lines. A second engine-table will be seen adjoining the goods-yard, which was found convenient, both to save time in turning, and to bring into use, with additional sidings, sundry corners of land which would otherwise have been wasted. The great defect in this station is the existence of a level crossing and a foot bridge close to the entrance, the thoroughfare being now a street, though originally but a narrow lane. Attempts have been made both by the public and by the Board of Trade to compel the companies to build a bridge, but neither being able to confer permissive or compulsory powers of purchase, nothing has been done in the matter.

Fig. 49 shows the outline of a station forming the terminus of a small single branch, the nature of the traffic on which necessarily admits of much simplification in all its arrangements. The trains being light, and only moving in one direction, a single platform suffices for passengers; but as goods are frequently attached to such trains, it becomes necessary to combine the goods-yard as intimately as possible with the passenger lines, so as to avoid loss of time on the arrival of the trains, and to clear the trucks, and leave the carriages ready for going out again, when the engine has been turned and brought round. On short branches, to which alone the single-line system ought to be confined, it is generally an object to despatch the incoming train back again as soon after its arrival as the engine can be connected for the purpose. It is therefore convenient to place the engine-table at the end of the station, beyond the platform, instead of connecting it with the engine-shed, as heretofore recommended, so that the engine may be turned round, run round the train by means of the middle spare line, and be hooked on, ready for starting, with the least possible delay, the coke and water being taken out after these operations, and while the outgoing train is being loaded. A station of this character should always be so arranged that a second line of way, as well as spare lines, may be added without involving the removal of any permanent works or buildings; in fact, it should combine in one the character both of a terminal and of an intermediate station. This rule will determine the position of the warehouses, goods and coal-yards, engine-shed, &c., and regulate the number of sidings. Reference to fig. 49 will show that such a course can be adopted by the simple removal of the carriage and cattle docks to the goods-yard, and of the engine-table entirely, the latter being no longer requisite. The position of the engine-table is convenient for working the goods traffic, and obviates the necessity for using any smaller ones. Attention may also be drawn to placing the warehouse directly opposite the offices, as affording facility for throwing a light roof from one to the other, to serve as shelter to the platform, and as cover for the spare carriages. Every such station should be provided with gas-works, large enough not only to supply its own lights, but the town also; as in most cases it will be found that the inhabitants are desirous of such a convenience. The proceeds from the sale of the gas and the carriage of coals will secure a handsome profit to the company, and the introduction of gas-lighting will encourage improvements in the town tending to increase traffic. The same course may be recommended with regard to water-works, when the station stands high, and good water can be obtained on the spot; added to which, there is economy in combining the gas-retorts with the boiler furnace. Too much stress cannot be laid on the importance of providing at first abundant space for goods traffic, with large yards for coal, lime, timber, &c., and plenty of siding space. Such traffic is generally by far the most remunerative for some time after the opening of a line of the nature indicated, and can only be secured by offering greater facilities. It should also be noted, that it is desirable, for reasons previously urged, to combine with the station comfortable residences for the station-master, porters, engine-drivers, and guards.

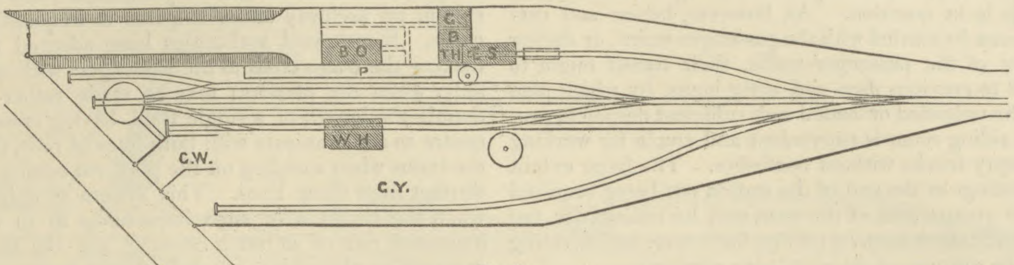

Fig. 49.
Branch Terminal Station.—Single Line.

Before leaving the subject of terminal stations, attention may be directed to one of a class indicated in fig. 50, the arrangements of which are peculiarly adapted for the working of unusually heavy passenger traffic on particular occasions, such as races or fairs. These consist mainly in placing a large number and considerable length of spare sidings at each end of the platforms, to admit of trains arriving, discharging, and drawing out of the way in rapid succession, and *vice versâ* on the return journeys. This system has worked very satisfactorily, and enables an almost unlimited amount of traffic to be conducted with perfect ease and safety. It may be objected, that with two platforms there will be

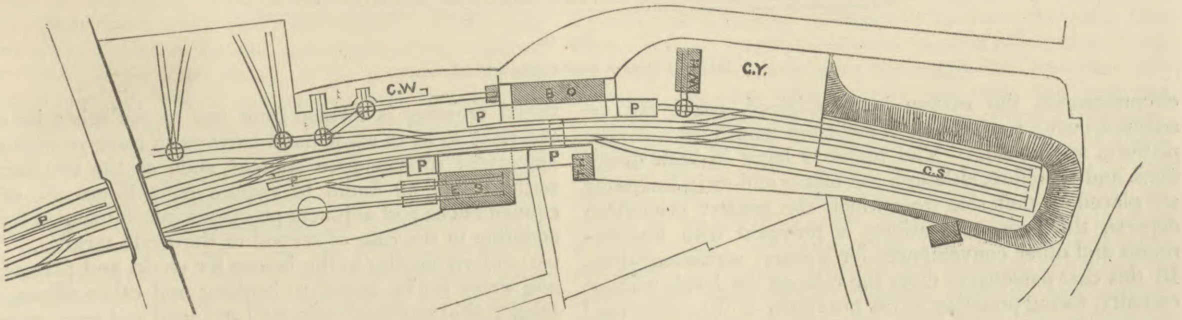

Fig. 50.
Branch Terminal Station for heavy Passenger Traffic.

some danger in crossing to the one opposite the offices; but in practice it is found that one platform only is necessary, as the traffic will always be in one direction at the same time. The second platform is convenient for special or foreign trains; and all danger can be avoided by connecting the two by a bridge over or under, though such an expedient is objectionable for this class of traffic. The small extent of carriage and horse docks may also be thought a defect when race traffic is in question. As, however, horses and carriages cannot be carried with the passenger-trains, or during the height of the passenger-traffic, their transit ought to be limited to previous days and early hours, by which plan they can be unloaded or loaded with sufficient despatch, provided the siding room is convenient and ample for working off the empty trucks without confusion. The large extent of spare sidings at the end of the station not being required during the greater part of the year, may be utilized for the time, to much advantage, by roofing them over, and devoting them to the purpose of stowing spare carriages.

Intermediate Stations.—Intermediate stations vary to a greater degree than terminals. The area to be occupied will naturally depend on the importance of the town, village, or district to be served; the character of the works on that of the railway where the station is to be placed; and the position of the offices, warehouses, and other buildings, on the special requirements of the traffic in each case. As respects extent of space and accommodation in the way of works, it has already been suggested that it is best to err, if at all, on the side of extravagance; but the situation of the offices, waiting-rooms, &c., relative to the platforms and lines of rails, when there are more than one, is a point of considerable importance. When the station is situated midway between towns of such extent as to cause an equal flow of traffic in each direction, offices may be requisite on both sides of the line; but where the bulk of the traffic tends one way only, it will be desirable to concentrate them on that side which involves the larger number of passengers and the greater extent of waiting space. This rule, again, will be modified by the position of the town or the district from whence the traffic is to be derived, especially if the railway lies on the natural surface, and adjoins a public road, whether crossing on the level or otherwise. This last condition is the most frequent one; and as some portion at least of the traffic must be expected to depart from the platform opposite to the offices, provision must be made for crossing with the least amount of danger to the public. When the passengers are numerous in both directions, over-bridges, as before stated, are objectionable; and in a surface-station an archway under the line is frequently impracticable. Some good authorities have adopted the plan of making the trains cross to the passengers with one platform only, when the platform may be made rather more than double the length of a single train, having crossings in the centre to communicate with both lines of rails, thus placing the trains when standing on the platform upon a loop-siding distinct from those lines. This system is only admissible when the traffic is of such importance as to warrant the increased risk of so much crossing, and the extra cost of maintaining the additional staff of men necessary to insure safety; in fact, it should never be adopted unless where all the trains are likely to stop, as the number of facing-points increases the elements of danger and of delay to the thorough traffic. Much will also depend upon the probable uniformity in the length of all the trains, as it is obvious that special provision must be made for the longest possible train to approach and to leave each station without interfering with the other; so that if there is much variation in the general length, unnecessary expense may be incurred without commensurate advantage. At the same time, it must be admitted that this system offers great convenience to the public when there is much first-class traffic and a large quantity of baggage; and it is especially applicable when the station partakes of the character of a terminal one, or is used as a receiver from branch or neighbouring lines, offering, as it does, great facilities for making up and receiving trains which may run over a portion only of the main lines, as well as for attaching and detaching the carriages intended or used for branch traffic.

An example is given (see fig. 51) of a large station where from the position of a level crossing, combined with other circumstances, the system last explained could not be adopted, owing to the want of sufficient length for a double platform on one side. The traffic is large in both directions, and therefore, although the offices and main buildings are placed on that side from which the greater proportion departs, the opposite platform is provided with waiting-rooms and other conveniences for general accommodation. In this case passengers cross the rails on the level, without casualty, owing probably to the proximity of the public road crossing where policemen are always in attendance. The placing of the platform wall opposite to the main buildings affords facilities for throwing a roof over in one span, which shelters both platforms most effectually at the least cost; and hence a satisfactory result is obtained, as there is a considerable amount of luggage to be conveyed across from one platform to the other. The extremities of both are furnished with easy inclines paved with smooth stones, and a paved crossing is formed from one to the other between the rails, so as to allow hand-barrows to traverse with ease. Important intermediate stations, such as the two last described, will be found to require most, if not all, of the conveniences and adjuncts previously recommended for the adoption in the case of second or third rate termini. This particularly applies to the houses for clerks and porters, gas and water works, complete booking and other offices, with comfortable waiting-rooms, well arranged and spacious warehouses for goods and coal and timber yards, with as much length of siding as can be obtained. Relative to the construction of houses for the company's servants, in connection with the general business premises, it may not be out of place to observe that there should be no door to communicate between the residence and any of the offices, both because such facilities frequently lead either to robberies or to neglect of duty, and especially because the whole

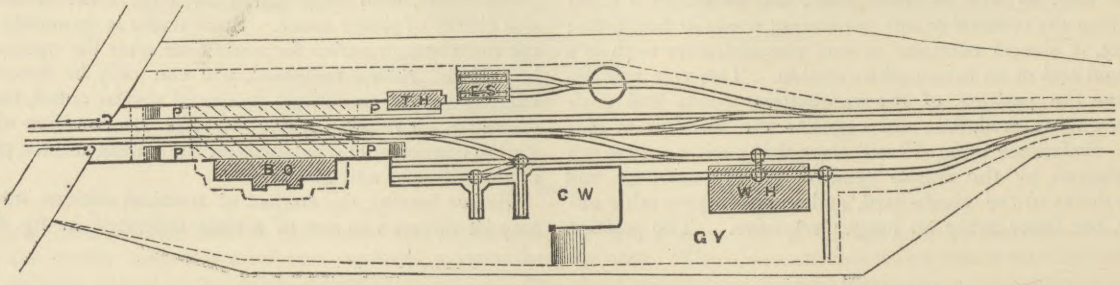

Fig. 51.

Railway Station with opposed Platforms.

block of buildings will be rendered liable to rates and taxes as an inhabited house.

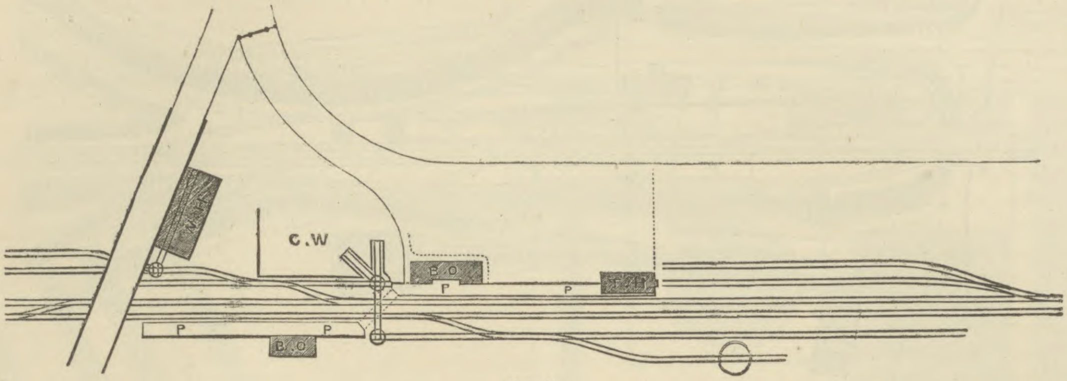

Fig. 52.
Railway Station with alternate Platforms.

The leading defect in the arrangement of the platforms (fig. 51), where no foot-bridge over or under is provided, lies in the difficulty of crossing where two trains arrive at the same time. This is sometimes met by arranging the platforms as shown in fig. 52, where the end of one is placed nearly opposite to that of the other, with a paved crossing between them, so that a clear space can always be maintained between the ends of the two trains when standing at the platforms. Such a plan offers many facilities for connecting sidings with the main lines and with one another, but is open to the objection of increased cost in consequence of the extra length, and is not popular with the public, on account of the greater distance to be traversed both by passengers and luggage.

It has already been urged, that when a station is necessarily situated on an embankment or in a cutting, it is true economy, in the first instance, to raise or to excavate a sufficient area to allow of conducting the whole of the business at the platform level, with easy inclined approaches to and from the public road. This applies particularly to cases where there is much "long" passenger traffic with heavy luggage, besides the ordinary horses, carriage, cattle, and goods business. Steps up or down ought, as a general rule, to be avoided at any cost; but when the station is situated near any large town, so that the traffic is chiefly confined to passengers, they may be adopted with some advantage, particularly if the line is in a cutting, and the offices can be placed over it and adjoining the public road-bridge, as at New Cross Station, near London. Peculiar facilities are offered by this plan when communication is desired with a middle platform, as must be the case when three or four lines of rails are used. It will then, however, be found necessary to build waiting-rooms on each platform, as the public will not be content to remain on the upper level until the trains arrive. There may also be some objection to the separation of the station-master from his platform duties, if he is confined to the booking-office; but this is partially met by the facilities given for general supervision over the subordinates below, as well as for an economical and simple concentration of the entire business of the station. A somewhat similar system is available when the station is on an embankment, and the offices can be constructed in connection with a bridge over the public road. But the advantages are by no means the same, as there is no power of supervision from the office; whilst the public will always object to the inevitable darkness, damp, and noise. Nor are there the same reasons for adopting the plan, as it is easy upon an embankment to place the offices on one side, and to connect them with the opposite or intermediate platforms by means of archways under the rails, which are not objectionable if well lighted and ventilated.

The junction station is a special variety of the intermediate or local class, which presents questions of too much importance and interest to be dismissed without distinct notice, however brief. Where two double lines of railway converge, it is frequently open to the engineer either to place the buildings and yards in the fork between the two, or beyond the point of junction. When the means of access for the public and of communication between the platforms are equally convenient, in either case he will be guided in his decision by the peculiarities of the traffic. If the branch or secondary line is simply a feeder to the main trunk, and the trains on both are worked in connection with each other, whether by attaching or detaching special carriages, or by transferring the passengers, the balance of convenience will lie with the second system, provided the sidings are so arranged as to enable the branch or subsidiary trains to clear the main lines before the others are due. If, on the other hand, the two lines joining belong to distinct companies, or are worked independently of each other, it will be far more convenient to adopt the first system, because two trains in both directions can draw up at the same time, without interference with each other, and special conveniences for accommodating subsidiary traffic or varying the size of the several trains can be arranged with the greatest facility. Judging from the general practice throughout the country, the latter seems to have become the more popular course.

Junction-stations for single-line branches may be arranged with greater simplicity, as the traffic upon them is generally of less magnitude, so that passengers and luggage can be transferred over a platform without the necessity of attaching or detaching carriages to or from the main line train. Fig. 53 supplies instances to meet either case, being the plan of a junction with two single-line branches, one of which connects directly with the main line, and the other only through the medium of an intervening platform, facing-points in both cases being avoided. On such a system, the offices will be placed on the side opposite to the through-line, the several platforms being connected by means of an archway under them and the rails wherever it is practicable. Waiting-rooms and their adjuncts must necessarily be placed on the further platform, and a roof in one or more spans should cover the platforms and sidings, such roofs being inclosed on both sides, and, as far as practicable, at the ends, to protect the passengers from the weather, to which their exposed position will render them peculiarly liable. Engine and tank houses, gas-works, engine-tables, and rooms for the men employed, will also prove as essential a portion of the general arrangements as in the case of terminal stations.

King's Cross station (Plate V.) is the most recently constructed, and the most extensive metropolitan station. It was built originally for the use of the Great Northern Railway only; but has recently been modified and extended in the goods department to accommodate the traffic of the Midland Railway, which, by an extension across the country from Leicester station to Hitchin station, on the Great Northern line, has found an entry into London by King's Cross, independently of the London and North-Western route. The whole station, for passenger and goods traffic, and for the purposes of the locomotive department, covers 26 acres of ground, and contains 18½ miles of lines of rail. The ground from King's Cross to Holloway, 1½ mile long, comprising the ground covered by the passenger and the goods stations at King's Cross, cost about L.470,000.

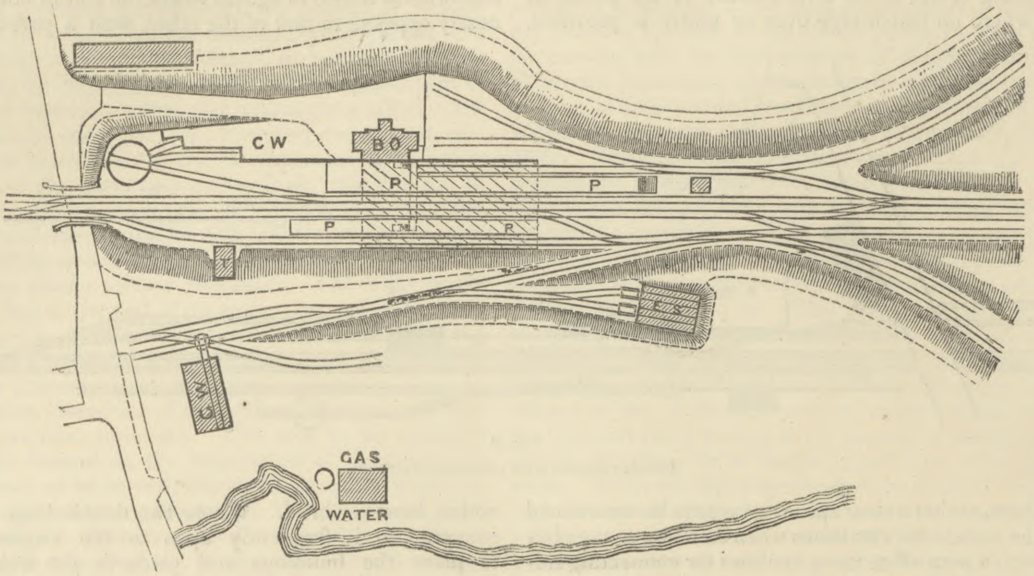

Fig. 53.
Railway Junction Station, having two Single-line Branches.

Huntingdon station, on the Great Northern Railway (see Plate V.) is one of the principal intermediate stations on the line. The station-yards are bounded by a road at one end and a river at the other, and the platforms are necessarily opposed. The main line is kept entirely free of turntables, which are placed only on sidings. The station is 760 yards in length, or nearly half a mile, between extreme points, and there are 3430 yards of siding, single line, or about 2 miles of siding in all, besides the up and down through lines.

The ordinary stations on this line are, with a wise economy, constructed to accommodate a great expansion of traffic. They are 700 to 800 yards in length, between extreme points, or nearly half a mile, and they contain about 2000 yards of sidings, single line, or more than a mile total length.

EXTENT OF SIDINGS.

The increasing traffic of the older railways has led necessarily to a greater use of the side lines, an increase of siding room, and an extension of stations. The distribution of siding accommodation on the London and North-Western Railway, as it existed in 1853, is instructive. On the main line of the southern division, from London to Birmingham, 113 miles, there were in all 53 miles of siding, single line; and on the total length of line, 315 miles, there were 88 miles of siding, single line:—in the proportion of about half the whole length for the trunk, and above a fourth for the whole division, or one mile of sidings, single line, to 3⅝ miles of railway. For the total length of railway, 635 miles, there is one mile of siding, single line, to 5½ miles of railway,—the stations averaging about four miles apart. The great preparation for the accommodation of the traffic, thus forcibly indicated by the proportion of siding room, suggests the great magnitude of the business done.

The stations of the Great Northern Railway are placed at average distances of 4 miles apart; so that the sidings of ordinary stations, each containing 2000 yards of single line, average of themselves more than one-fourth of the whole length of the railway. At King's Cross station there are 18½ miles of siding; and it may be assumed that there are many more miles of extra sidings at the principal stations down the line. The total length of siding accommodation on the whole line would then amount to one-third of the length of the railway, or one mile of siding for every three miles of railway. It would thus appear that the Great Northern Railway company have forestalled the demand for siding-room, which, in the experience of the older lines, has been found necessary, to meet the demands of growing traffic.

In estimating the total length of sidings on the whole railway system, it should be known that there were in 1858 upwards of 2950 railway stations in England, Scotland, and Ireland, for 9082 miles open for passenger traffic in that year; being at about the average rate of one station for every three miles of railway.

From what has been said, one mile of siding, single line, may be taken as the average allowance per station, including, of course, terminal accommodation of every description, which would show that the total extent of single line laid for sidings averaged one-third of the total mileage of railways. In addition, therefore, to the 9116 miles of line open for passenger and goods traffic, or for goods only, in 1857, of which 30 per cent. were only single line, there were 3000 miles of siding; which would make a total of upwards of 18,000 miles of single line in Great Britain and Ireland.

LOCOMOTIVE-STATIONS.

Locomotive-stations should be situated at or near the principal terminus of the railway, sufficiently near to a large town to insure the facility for obtaining materials and workmen; and sufficiently far off to be clear of the heavy local taxes with which such large establishments in all large towns are burdened.

The locomotive-station of the Manchester, Sheffield, and Lincolnshire Railway is selected for illustration. It is situated at Gorton, about two miles from Manchester, the first position where the railway and the land take the same level. The total quantity of land purchased is nearly twenty acres, about nine of which are occupied by the workshops and store-yard; the remainder is used for the construction of reservoirs for supplying the works with water, and for erecting cottages upon it for the work-people in the company's service.

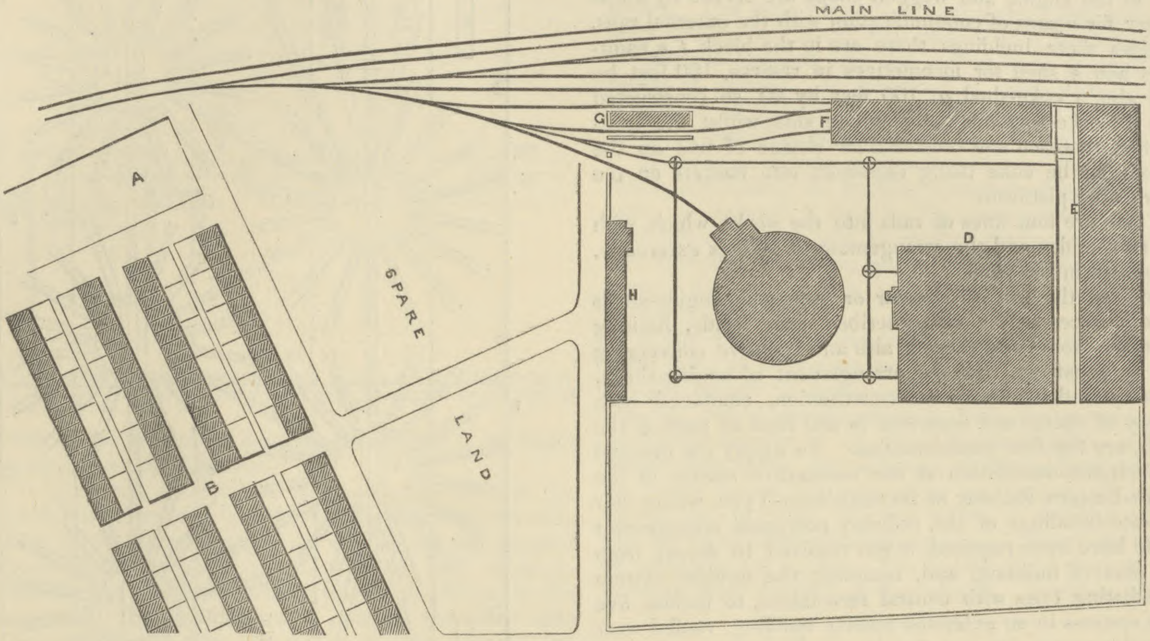

Fig. 54.
Gorton Locomotive-Station, on the Manchester, Sheffield, and Lincolnshire Railway.

The block-plan (fig. 54), shows the general arrangement and relative positions of the shops, cottages, reservoirs, &c. The reservoirs *a* are calculated to hold a month's consumption of water, and are supplied from the adjoining canal, the water passing through filter-beds in its course from the canal to the reservoirs. These reservoirs, from their elevated position, supply the water directly into the tenders upon the railway, and throughout the workshops, the canal being at a sufficiently high level to supply them. The cottages *b* are 140 in number, arranged in four blocks. The plan of the works is nearly square, the entrances being placed towards the cottages on the east side of the works; and adjoining are the offices and general stores *h*.

The engine-house, or shed for engines on duty, *c*, is a rotunda of 150 feet in diameter inside, and is capable of holding seventeen engines with their tenders, leaving the entrance and exit lines clear. The advantage of this arrangement, shown more in detail (fig. 55), over the ordinary polygonal engine-house, is in the absence of pillars for supporting the roof, of which there are twelve for a twelve-sided polygon; in this building there is but one column at the centre. To the left of the entrance is a furnace for holding live fuel, from which the engines are lighted; and there are two lines of rail across the central turn-table, on one of which the engines enter, and on the other depart. Between the rails of each radiating line a pit is constructed to afford access below the engines for inspection. The roof is of wrought iron, surmounted by a louvre for ventilation, which is glazed to admit light freely. To the left of the rotunda are the workshops, with stationary engine-house and boiler. The fitting and tool shop contained in the block *d*, is 120 feet by 60 feet, and contains nearly the whole of the tools. The smiths'-shop is contiguous to the fitting-shop, in the same block, and of equal dimensions; it contains sixteen smiths' fires, eight on each side. Next to this is the boiler-shop, of the same size, with eight smiths' fires and four fires for heating boiler-plates, and a finishing and shearing machine. Next to these is the erecting-shop, 150 feet long by 60 feet wide, containing nine transverse lines of rails, each to hold two engines; so that eighteen engines may be housed here at once. There are travelling cranes in the shop which traverse it for its full length, and capable of lifting any engine and moving it to any part of the shop.

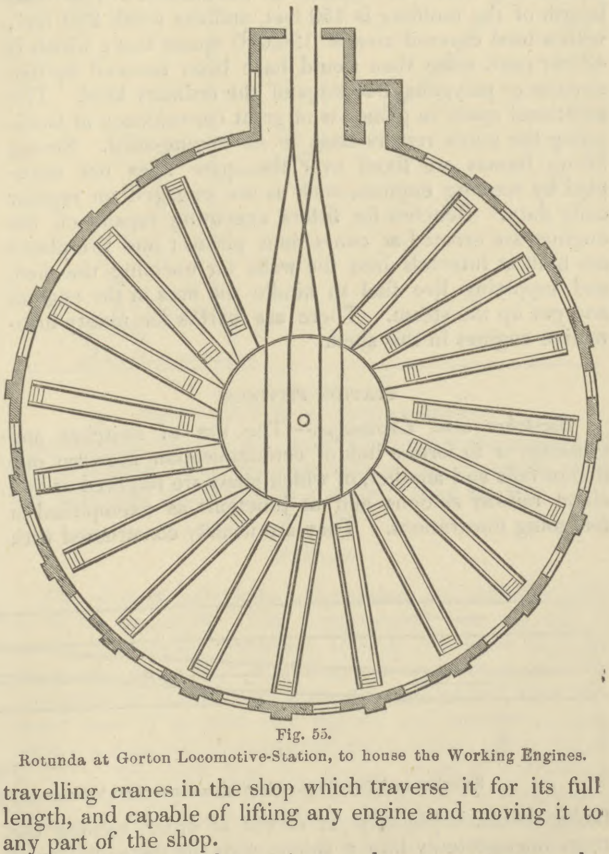

Fig. 55.
Rotunda at Gorton Locomotive-Station, to house the Working Engines.

To the left are the carriage and waggon shops *e*, the waggons being on the ground floor and the carriages above, to which elevation they are raised by a self-acting worm-

Station Fittings.

hoist worked by the stationary engine. These shops are 320 feet by 70 feet, and can receive fifty waggons and thirty-eight carriages; and attached to them are the lifting-room and the trimming and saddlery room. The lines of rail in the engine and waggon shops are served by a traverser, for means of communication with the external rails. Besides these buildings there are in the block *f* a paint-shop and a shed for locomotives in reserve, 160 feet by 40; also, a coke-shed *g*, 100 feet by 40, so constructed that the coke-waggons stand on one side, whilst the locomotives approach and receive their charge of fuel on the other side, the coke being measured into baskets on the intervening platform.

There are four lines of rails into the works, which, with the turn-tables and the arrangement of sidings externally, are shown in the plan.

But, in the use of circular or polygonal engine-sheds there is necessarily a circumscribed space inside, limiting the spare room; and there is also an expensive converging roof to construct. In the arrangement of engine-sheds, capacity and economy of construction, combined with facility of access and departure to and from all parts of the sheds, are the first considerations. To supply the demand for such accommodation at the locomotive station of the North-Eastern Railway at Newcastle-on-Tyne, where four separate buildings of the ordinary polygonal arrangement would have been required, it was resolved to depart from this plan of building, and, retaining the circular system of radiating lines with central turn-tables, to inclose five such systems in an extended oblong building, roofed over its entire area in five parallel bays, supported on the side walls and on four rows of columns. (See fig. 56.) The circular systems, as arranged in two rows, and alternating with each other, afford numerous direct lines of communication from one system to the others. The total length of the building is 450 feet, and the width 280 feet, with a total covered area of 126,000 square feet; which is 43 per cent. more than would have been covered by five circular or polygonal buildings of the ordinary kind. The additional space so gained is of great convenience in facilitating the minor repairs done in an engine-shed. Strong lifting frames are fixed over the spare lines not occupied by running engines, such as are engaged on regular daily duty. Benches for fitters executing repairs on the engines are erected at convenient places; and fire-places are built at intervals into the walls for warming the shed, and supplying live fuel to kindle the fires in the engines and get up the steam. There are berths for ninety locomotive engines in this shed.

STATION FITTINGS.

Switches and Crossings.—The use of switches and crossings is to form a link of communication between one line of rails and another, of which many are required at and about railway stations and at junctions, as exemplified in foregoing illustrations. They are usually constructed with ordinary rails, and are carried in cast-iron chairs spiked down to sleepers. The switch-rails are moveable, and are worked by rods to which heavy weights are attached; the function of the weights being to retain the points in one position, and to act as a self-acting adjustment in restoring them to it—their normal position—after having been shifted for the passage of a train. (See figs. 57 and 58.)

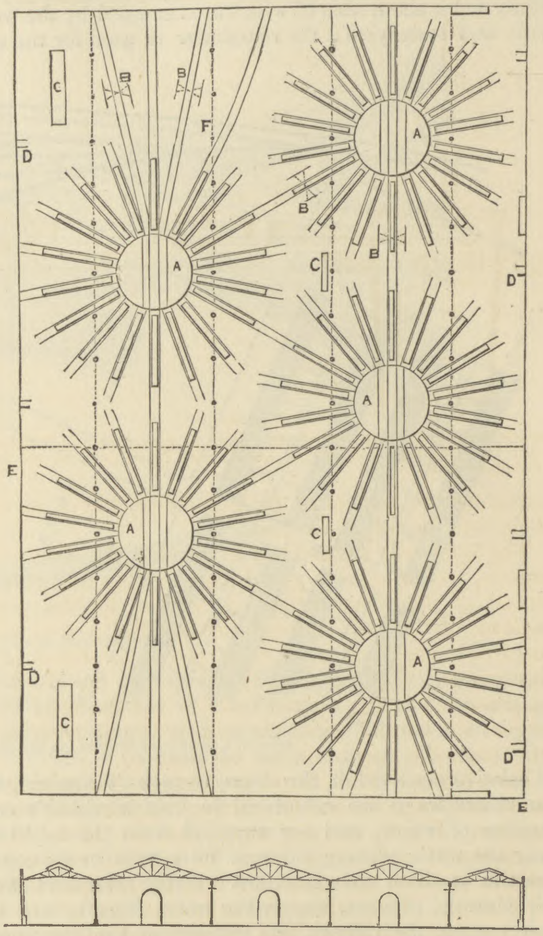

Fig. 56.
Locomotive Engine-Shed on the North-Eastern Railway.—A, Turn-tables; B, Lifting-frames; C, Fitters' Benches; D, Fire-places.

When only one of the terminal rails is moveable, it is called a single switch, and is used only on sidings or branch lines of rail; the double switches being more perfect in action, are adopted on the main line; and, as a general rule, switches on the main line are ordered to be laid with the points in the direction of the traffic, so that passing trains may run out of the points, and not into them. "Facing-points," as they are termed, are such as are laid on the main line, facing or pointing towards the regular advancing trains. Many accidents have been caused to trains by facing-points, improperly set or out of order, turning the train unexpectedly into a siding, with the impossibility of pulling up in time to prevent a collision; or throwing the train off the rails altogether, producing what is called "derailment" in modern railway parlance. So dangerous are facing-points felt to be, particularly on high-speed lines, that on some railways they are absolutely forbidden at all except terminal stations, and at intermediate stations

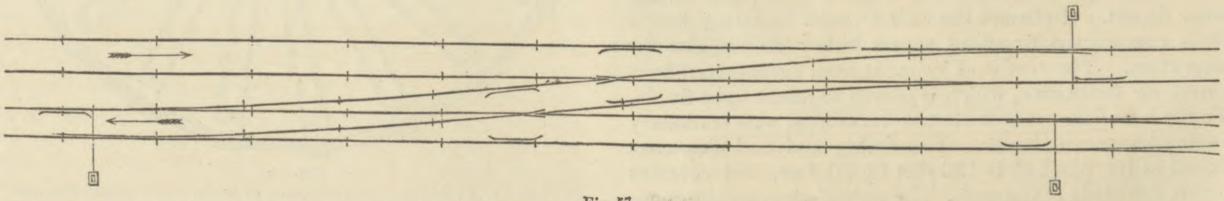

Fig. 57.
Switches and Crossings.—Showing a connection between two lines of rail, and the position of the Switches, Boxes, and Rods.

where every train is ordered to stop. In some situations this rule can only be followed by sacrificing simplicity and increasing the number of backing-points, but it no doubt diminishes the risk of accident.

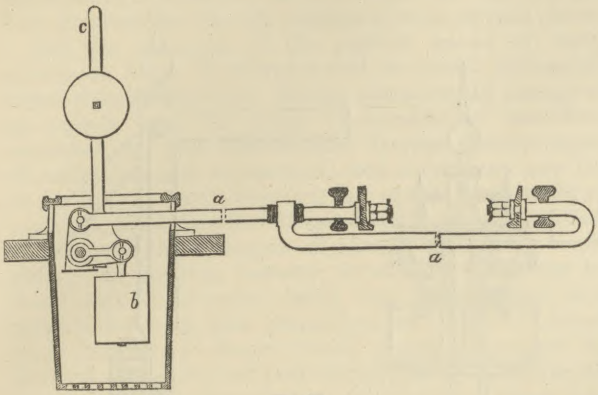

Fig. 58.
Switch-Box.—Rod *a* attached to the Points to work them; *b*, Weight to retain the Points in position; *c*, Lever, with Disc-signal, to act also as Counterweight.

The stock-rails are notched to receive the ends of the tongues, and in order to guard these notches from the rude contact of the wheel-flanges, as well as for the general guidance of the train through the switches and crossings, guard-rails are fixed at suitable places, as shown in the illustrations. In some designs of switches the fixed rails are preserved entire, without notches, and the sides of the tongues are housed under the rails, in lateral recesses; in these cases the guard-rails are not required.

Turn-tables.—These are of two classes—for turning carriages and waggons, and for turning engines and tenders together. For the carrying stock, they are 12 to 14 feet in diameter, sufficiently large to receive conveniently vehicles of which the wheels are 8 to 10 feet apart between the centres. Turn-tables ordinarily used are of cast-iron, carrying two transverse lines of rails, and revolve upon a central pivot, and conical rollers near the circumference, which are upheld and turn upon a cast-iron base bedded in cement, or on a built foundation. (See fig. 59.)

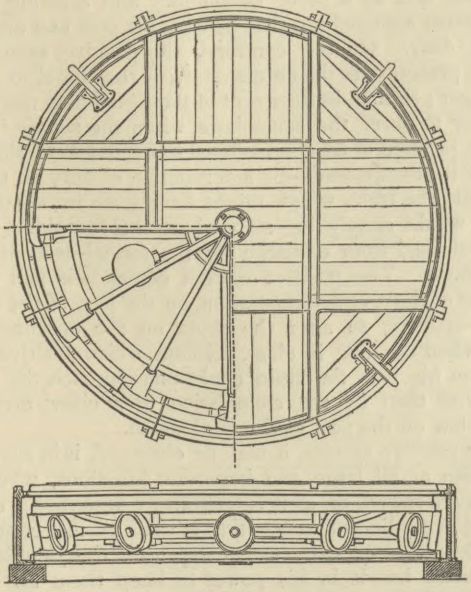

Fig. 59.
Carriage Turn-table, for Stations.

For turning engines and tenders together, and thus superseding the necessity formerly experienced of uncoupling them to be turned on small tables, turn-tables 40 feet long, or thereby, are required. A common plan of table consists of two longitudinal balks of timber, to carry a line of rails, framed together with cast-iron beams, to support the centre on a pivot and the extremities on rollers. The table revolves in a pit about 4 feet deep, on a large circular race of cast-iron bedded on a firm foundation, to carry the rollers, and the motive force is applied by means of gearing. In situations of much thoroughfare it is needful to extend the deck of the table laterally, like wings, to complete the circle, and so cover in the pit.

Traversers.—These are a convenient substitute for turn-tables, particularly for working a number of parallel lines of rails. A traverser is simply a low rectangular frame, made with two overhung rails, to receive carriages or waggons, and moveable on rollers across the lines of rail, so as to receive the carriage from any one line of rail, and deposit it on any other.

Water-cranes.—Water-cranes are erected at convenient spots for delivering water to the locomotives. The upright column is firmly erected, and contains the supply-pipe, which ascends within it from the ground. The horizontal member is in direct communication with the supply-pipe within the column; revolving freely, so as to be swung out of the way when not in use. It is sufficiently long to reach over the middle of the line of rails, and has attached to it a leathern hose to direct the current of water into the tender. The handle of the shut-off valve is shown near the base of the column. In other plans of water-cranes, the shut-off valve is placed at the upper end of the column, or at the extremity of the swinging pipe, and is opened and closed by a screw. (See fig. 60.)

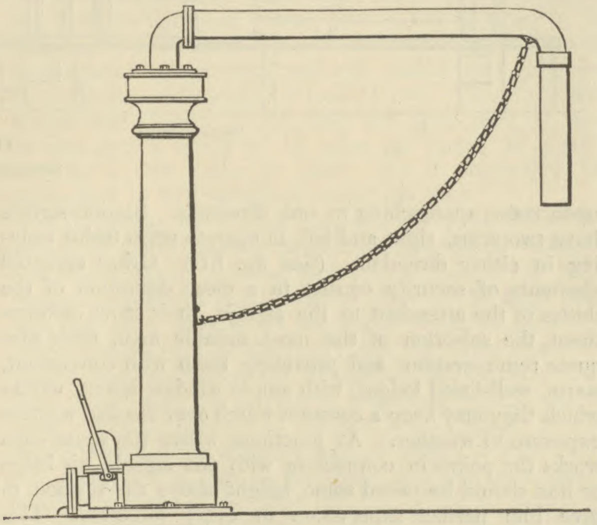

Fig. 60.
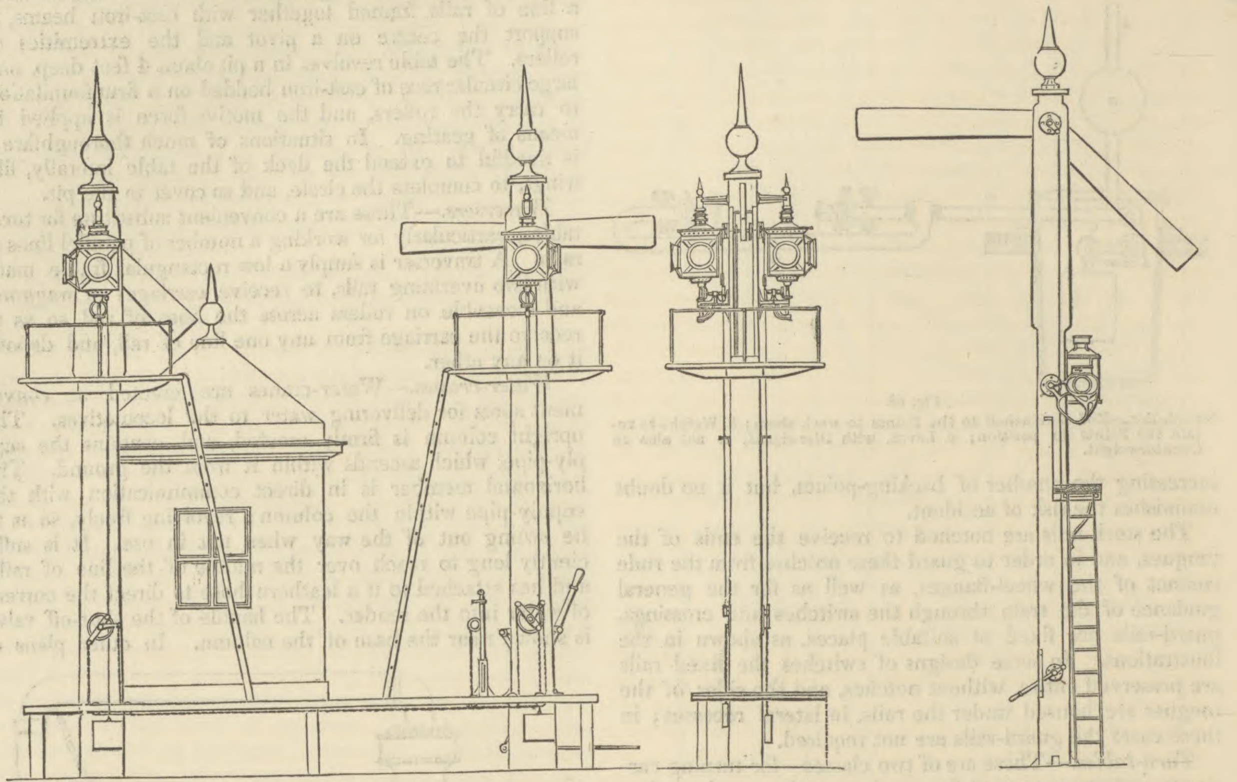
Water-Crane, to fill the Tenders of Engines.

SIGNALS.

The want of uniformity in the system and code of signals is to be regretted. The "semaphore" (see fig. 61) is now very generally employed, and has in a great measure superseded the "disc" as a means of signalling; but the companies do not all work it by the same code. One manager uses it to give two signals, and another to give three; a third will have an auxiliary or distant signal placed at 500 or 600 yards from the station, to act as a repeating signal, his neighbours perhaps preferring to use it only as a caution. There are companies which, rejecting the semaphores, use sundry varieties of the disc; and this, though simple and cheap, is limited in its application.

In the employment of the semaphore, the arm is turned straight out, perpendicular to the post, as the signal of danger; diagonally downwards, at an angle of 45°, as the signal of caution; and it is turned home, disappearing within the post, when the line is all right for the approach of the train. Distant-signals have but one arm, as they act only upon trains approaching in one direction. Station-signals have two arms, right and left, to operate upon trains arriving in either direction. (See fig. 61.) Other essential elements of security consist in a clear definition of the duties of the attendant to the signals, their strict enforcement, the selection of the most suitable men, their adequate remuneration, and providing them with convenient, warm, well-fitted lodges, with ample window-space, within which they may keep a constant watch over the line without exposure to weather. At junctions, where the signal-man works the points in connection with the signals, his lodge or box should be raised some height above the surface, to give him perfect supervision in every direction. This keeps him out of the way of gossips, and he is less likely to be distracted in the discharge of his duties. A similar precaution is of service at all other important signal-stations, even where points may not be wrought in connection with signals.



Junction Signals. *Station Signal.*

Fig. 61.
Semaphore Signals.

At night it is needful to supply the place of semaphores or discs by large and powerful lamps, with reflectors, capable of showing lights of three colours,—a white light, a blue or green light, and a red light,—signifying respectively safety, caution, danger. They are changed either by revolving the lamp on its axis, to present a different side with a differently-coloured glass, or by retaining the lamp as a fixture, and sliding differently-coloured glasses in "spectacle-eyes," or otherwise, before the light. Both of these methods of changing the signal are illustrated in the figures annexed.

Signalling has been a subject of much controversy; it has been distinguished by controversialists into two systems,—the "positive" system, and the "negative" system. The so-called negative system is in fact the current practice of the day; and by the epithet "negative" it is implied that, inasmuch as the normal state of the signal is that of caution, or that of safety, as the practice may be, and as it is only turned on to danger when specially required for the protection of the station on the line, the habitual caution or safety-signal is in effect no real signal at all, as except in cases of danger it does not demand any active demonstration from the signal-man as to the state of the line, and as a proof satisfactory and assuring to the engineman approaching that he is at his post and attending to his duty. On the contrary, the positive system, so-called, presupposes the normal state of the signal to be that of danger; so that, in the event of the signal-man neglecting his duty to lower the semaphore when the station is clear for the passage of an approaching train, it will at the most —so it is presupposed—be a dereliction of duty on the safe side, and the train, which might have gone innocently forward, would simply be stopped at the forbidding signal until released from embargo by the formal descent of the semaphore. The positive system demands in fact a positive act of duty, or demonstration, on the part of the signal-man,—namely, to alter the signal on the approach of a train when the line is clear, without which positive act of duty on his part the train could not approach the station otherwise than by the commission of a clear breach of signal-law on the part of the engineman.

The positive system, it may be observed, is in successful operation at all large and important junctions, where the signals are raised, or, as it is technically described "closed" against every line of rails,—that is their normal condition; and when one or more trains approach the junction, the signal-man has it in his power to keep them all out, or to "open" the signals, one at a time, for the safe and successive passage of the trains through the junction. In such a situation, the use of the positive system is manifestly conducive to the greatest degree of safety, as by the unavoidable intersections of the lines of rails there are many

Locomotive Power.

chances of collision. Peculiar situations of risk require peculiarly stringent codes of signals, and the exceptional character of the situation, and of the system of signals, is the best guarantee for the safe conduct of trains at such places.

But the extension of the positive system to every station on a line of railway would, no doubt, thoroughly defeat the object in view. For the uninterrupted passage of an express train, the active co-operation of successive signalmen at 3-mile intervals (the average distance apart of stations) would be essential; and should any one fail in the duty of timely lowering the signal, there would of course be an interruption of speed and a loss of time, and all the consequent dangers of want of punctuality would ensue. In practice, however, it would undoubtedly be found that engine-men, losing their respect and their patience for such false precautions as signals of danger when there was no danger, would generally disregard the elevated semaphore, and push through, to the extensive and dangerous demoralisation of engine-men and signal-men. It appears to be overlooked that the human brain is an indispensable element of the machinery of signalization, and that simplicity in the working of the brain is an element in the question, just as simplicity is, in the manœuvring of the semaphore. The use of the electric telegraph will be considered in treating of railway accidents.

LOCOMOTIVE POWER.

It is hardly necessary to observe that a locomotive engine differs in many particulars from other steam-engines. The source of power—the principle of mechanical life—is a point of agreement; it determines the order to which the locomotive naturally belongs. But in this we have a new species, adapted to other purposes, and possessing different capabilities. The machine, as its name imports, is intended for locomotion; and in order that it may fulfil its purpose, it must carry along with it the fuel and water which are necessary to maintain its action. This condition implies compactness and lightness of construction, combined with the requisite power. To obtain those first, the engine and boiler are united together in the same machine, and the parts are made of much smaller dimensions, in proportion to the power, than in other steam-engines. The requisite power is obtained by using steam of very high pressure—of such a pressure as will allow the steam-cylinders, when the power is developed, to be of small capacity; but, in order to obtain steam in sufficient quantity and of sufficient pressure from a boiler which must also be portable, it was necessary to depart from the common form, and to adopt a mode of construction by which the evaporative power of the boiler—that is, its power of generating steam—would be greatly augmented. The condition of locomotion at high velocity in so weighty a mass as the lightest and most compact locomotive must be, implies, moreover, subjection to violent strains and shocks, which must as far as possible be provided against by strength and firmness in the framing together of the whole.

It may readily be conceived that locomotive machines did not at once start into their present state of approximate perfection, but have been gradually matured by successive modifications and improvements. The first suggestion of the application of steam-power to the propelling of carriages is due to the illustrious Watt, who proposed it in 1759 to his friend Dr Robison, at Glasgow college. Oliver Evans, of Philadelphia, thought of the same thing in 1782, when he patented a "steam-waggon;" but it does not appear that anything more than a good high-pressure stationary engine was the result of his labours. In 1784 Mr Watt patented a locomotive carriage; and in the same year Mr Murdoch, his friend and assistant, constructed a non-condensing steam-locomotive of lilliputian dimensions. This locomotive was placed on three wheels; the boiler was of copper; the flue passed obliquely through it, and was heated by a spirit-lamp; the steam-cylinder was only ¾ths of an inch in diameter, with a stroke of 2 inches, turning a crank on the axle of the larger wheels, which were 9½ inches high. This little locomotive, standing not higher than 15 inches above the ground, could run at a speed of six or eight miles per hour.

Locomotive Power.

In 1804 Mr Richard Trevithick constructed a high-pressure locomotive for the Merthyr Tydvil Railway, in South Wales; but the great defect consisted in the slipping of the wheels, which Mr Blenkinsop endeavoured to obviate in 1811 by employing a rack-rail, in which a large toothed wheel was to work. In 1813 Mr Brunton of Butterley contrived a locomotive carriage, to be propelled by levers like horses' feet. In 1814 Mr George Stephenson constructed an engine for the Killingworth Railway, near Newcastle, in which toothed wheels were employed to engage and turn all the four wheels of the engine, and so to utilize all their adhesive power, to "bite" the rails.

The year 1829 is famous in the annals of railways for two things—the opening of the Liverpool and Manchester Railway, the type and forerunner of modern railways; and the invention and construction of the first high-speed locomotive of the standard modern type, the railway and the locomotive by Mr Stephenson and his son, Mr Robert Stephenson. This engine was made under competition for the Liverpool and Manchester Railway, and it gained the prize for lightness, power, and speed, awarded by the directors. It weighed 4 tons 5 cwt.; the tender following it weighed 3 tons 4 cwt.; and two loaded carriages drawn by it on the trial weighed 9 tons 11 cwt.; thus, the drawn weight was 12 tons 15 cwt., and the gross total 17 tons. It averaged a speed of 14 miles per hour; its greatest velocity was 29 miles per hour; and it evaporated 18¼ cubic feet, or 114 gallons of water, per hour.

This engine, the Rocket, comprised the three elements of efficiency of the modern locomotive, the internal water-surrounded fire-box, and the multitubular flue in the boiler, being a number of small tubes in place of one large tube; the blast-pipe, from which the waste steam of the engine was exhausted up the chimney; and the direct connection of the steam-cylinders, two in number, one on each side of the engine, with the driving or propelling wheels, on one axle. The subdivision of the flue into a number of small tubes proved to be of marvellous advantage in accelerating the absorption of heat by the water, and the generation of steam, in virtue of the great increase of heated surface exposed to the water, without adding to the size or weight of the boiler. But the evaporating tubes would have been of little avail practically had they not been supplemented by the blast-pipe in the chimney, which, by ejecting the steam from the engine after it had done its work in the cylinder, straight up the chimney, excited a strong draught through the boiler, and caused a brisk and rapid combustion of fuel, and generation of heat. The heat was absorbed with proportional rapidity through the newly-applied heating-tubes. The blast-pipe, thus designedly applied, was undoubtedly the invention of Mr Stephenson; in conjunction with the multitubular flue, it altered and vastly improved the range and capacity of the locomotive; and, in further conjunction with the direct connection of the steam-cylinder to one axle and pair of wheels, it was tantamount to a new and original machine.

Fledged and armed with wings, this locomotive, the Rocket, subsequently drew an average gross load of 40 tons behind the tender at 13·3 miles per hour. The old Killingworth engine could only work at a maximum of 6 miles per hour with 50 tons. The Rocket, in the earlier trial, attained a speed of 29 miles per hour. George Stephenson came eminently at the right time in scientific history, gathering into one magnificent fact all the floating prophecies of possibilities, solving the problem, and setting the question of the railway and the locomotive engine at rest for ever by his grand and masterly invention.

The key-note was struck. Constructors on all sides worked, each in his own way, at the locomotive, to improve the detail and increase the efficiency; and for many years the practice of builders was moulded into two general classes of engines, with two cylinders placed horizontally inside the smoke-box, under the chimney, and otherwise essentially similar to each other, except in one great feature, the number and disposition of the wheels. In one class there were six wheels, of which one pair was placed behind the boiler, typified in the engines of the day made by Mr Robert Stephenson; in the other class there were but four wheels, placed under the barrel of the boiler, leaving the fire-box overhung, typified in the engines made by Mr Bury for the London and Birmingham Railway. Experience has demonstrated the disadvantage of an overhung mass, with a very limited wheel basis, in the four-wheeled engine running at high speed; and now it is the general practice to apply six wheels to all ordinary locomotive stock.

The general features and characteristics of modern locomotive practice are represented by the illustrations (figs. 62 and 63). There are two leading types of passenger-engines, distinguished chiefly by the steam-cylinders being, in the first, situated within the framing, under the boiler, with the main driving axle cranked at two points to receive the power from the two cylinders; and in the second type, the steam-cylinders are placed external to the framing, and connected, not to the axle, which is straight, but to crank-pins fixed between the spokes of the wheels, in connection with the nave. From these distinguishing features, the two types of engines are known respectively as "inside-cylinder locomotives" and "outside-cylinder locomotives." In the latter, the general contour of the cylinders is usually visible at the fore-end of the machine. The tenders have six or four wheels, according to the taste of the designer, and they are supplied with powerful brakes, worked by screws, with blocks of wood placed against each wheel. A water-tank forms the upper part of the tender, namely, the two sides and the back, in the form of a horse-shoe, holding 800 to 1200 gallons; and in the hollow of the shoe the fuel is deposited, of which a full charge may weigh 30 cwt. to 2 tons. The engine and tender are suspended on springs placed over the axle-bearings.

Similarly, there are inside-cylinder goods locomotives, and outside-cylinder goods locomotives. In the former the wheels are all of one size, in order that the driving force may be transmitted from the central pair of wheels to the front and back pairs, by means of coupling-rods attached to crank-pins in the wheels, hence called a six-coupled engine. In the latter engine the hind-wheels only are coupled with the central wheels, and the fore-wheels are of less diameter, as, being free, they are not required to be so large; hence called a four-coupled engine. The six-coupled engine can take the heaviest train on a good straight railway,—that is, on one free, to a large extent, of curves or sudden turns in the line of direction of the train; but the four-coupled works most economically on curved lines, and may be made so as to take, in average practice, as heavy a load as the six-coupled engine.

American practice, after having passed through various phases, has arrived at two great types of locomotive for passengers and for goods traffic, which are universally adopted in the United States. The passenger-locomotive has eight wheels, of which four in front are placed in a moveable frame, called a "bogie" or "truck," which swivels on a central pivot, and adapts itself to the curves of the lines; the four wheels behind are the "drivers;" they are larger than the front wheels, and of equal size and coupled. The cylinders are placed outside, just over the truck, horizontally. A "cab" or "house" is placed upon the hinder part of the machine, behind the boiler, for the protection of the engine-driver and the stoker from the weather, with ample glazed opening, to afford a clear view ahead. The chimney or "stalk" is in form externally like an inverted cone, expanding upwards; internally, it is cylindrical, and the space between the outer and inner chimneys forms a reservoir for cinders and ashes thrown up through the inner chimney, which are deflected by a baffle-plate at the top, and thrown over into the reservoir, trap, or "spark-catcher." This contrivance is specially designed for the use of wood as fuel, and to prevent the risk of conflagration arising from the numerous sparks which would otherwise be discharged in passing through forests and other ignitable districts. As a further precaution for the prevention of sparks, the top of the stalk is covered with a fine wire-net. The steam-whistle is situated above the boiler for ordinary use; and the bell is hung near to the cab, with ropes within reach of the engineman. The bell is used in passing through the streets. The cow-catcher is hung in front of the engine, to ward off stray cattle, &c., and the American flag is hung behind it. The tender is carried on eight wheels, disposed under two trucks, fore and aft, to facilitate the turning of the tender on the curves. The goods-locomotive is placed on ten wheels, of which six are coupled, to supply driving-power, and the leading four wheels are hung in a swivelling truck.

Weight, Dimensions, and Cost of Locomotives.—The earliest four-wheeled engines made by Messrs Stephenson & Co. as an article of manufacture weighed 9 tons "with the steam up,"—that is, with a supply of fuel and water in the boiler. The six-wheeled engines weighed 11½ tons. An ordinary passenger-locomotive of the present time weighs 19 to 23 tons, and occasionally as much as 27 tons, which is excessive. A goods-locomotive of the most powerful stamp weighs 27 to 32 tons, distributed on six-coupled wheels. Tenders weigh from 10 to 15 tons, with fuel and water supply. Tank-locomotives, or such as are constructed to carry their supply of fuel and water in reserve, without the aid of a tender, weigh a few tons heavier than the same engine if fitted with a tender. But tank-locomotives are usually made of small size, to work light, branch traffic, and weigh lighter in consequence than most other engines,—from 12 to 20 tons gross. The Great Western broad-gauge 8-wheel passenger-engines weigh 35 tons, or with tender, 50 tons. The goods-engines are not so heavy, weighing about 30 tons, or with tender, 45 tons. But the heavy tank-engines used on the steep lines of South Wales and elsewhere weigh 40 tons gross.

Passenger-locomotives are commonly made with cylinders 15 or 16 inches in diameter, with a stroke of 20 to 24 inches, and driving-wheels varying from 5½ to 7 feet diameter, according to the duty for which the engine is made; for high-speed express trains the larger wheel is used. The cost of a modern passenger-locomotive and tender is about L.2300.

Ordinary goods-locomotives have cylinders 16 inches diameter, and 24 inches stroke, with 5 feet wheels. They cost about L.2800 with tender.

The fire-grates are 3 feet to 4 feet in length, and about 3 feet 6 inches wide; and the boilers contain 150 to 230 small flue-tubes, about 2 inches in diameter, and 10 to 11 feet in length. Some account of the performances of locomotives will be given in another section. The comparative magnitudes of recent broad-guage and narrow-guage engines and tenders may be apprehended from the skeleton elevations (figs. 62 and 63).

Carriages and Waggons.

Carriages and Waggons.

CARRIAGES AND WAGGONS.

The carriage-stock comprises all vehicles concerned in the conveyance of passengers and their luggage, and of private carriages and horses, the vehicles to carry the latter usually being attached to, and run as part of, the passenger train in which their owners are conveyed. The waggon stock comprises the vehicles employed in the conveyance of merchandise, minerals, and live stock. The common varieties of vehicles employed in railway traffic are as follows:—

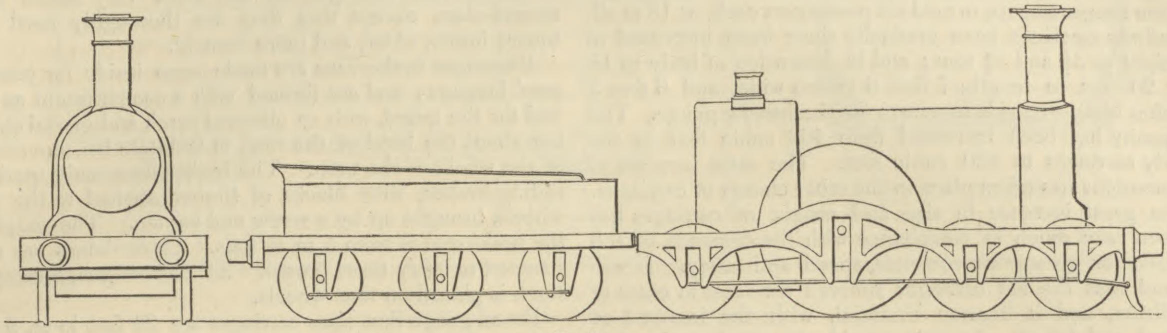


Fig. 62.

Broad-Guage Passenger Locomotive (skeleton elevation).

Passenger-train Stock.—First-class carriage, second-class carriage, third-class carriage, composite carriage, luggage brake-van, horse-box, carriage-truck. To these may be added the mail-carriage or travelling post-office.

Goods-train Stock.—Platform-waggon, open or box waggon, high-sided round-end waggon, covered goods-waggon, cattle-waggon, sheep-waggon, coal-waggon, coke-waggon, brake-van.

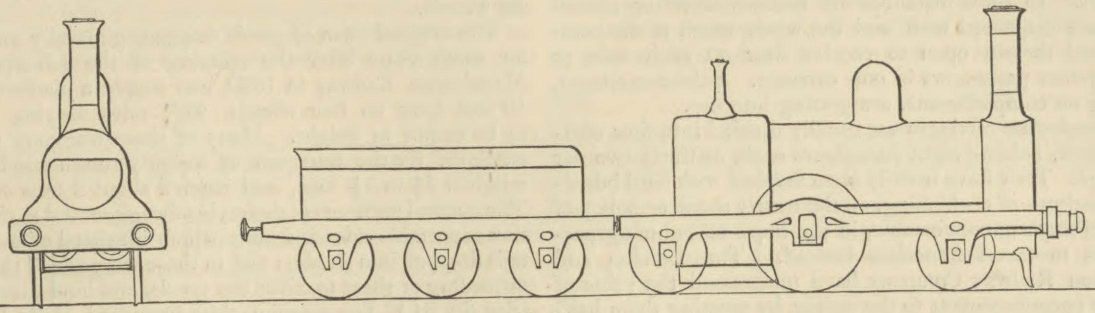

Fig. 63.

Narrow-Guage Passenger Locomotive (skeleton elevation).

Besides these, there are other waggons specially designed for special traffic, as gunpowder, salt, and lime. Also ballast-waggons, for the private use of the engineer's department.

The classification of carriages is designed to meet the various requirements of the travelling public; some preferring seclusion, ease, luxury, high speed; others preferring society, if tolerable, and economy, with moderate comfort and moderate speed; others looking to economy simply. For the sake of uniformity externally, and in many of the details, carriages are usually made of the same external length, width, and height, and suitably in the interior. The under-works of the stock may thus be identical in construction, and a uniformity of working and wearing parts is thus secured, which is conducive to economy of maintenance.

The waggon-stock should be as nearly uniform as possible. Uniformity of waggons is more important than that of carriages, as their total number and cost are much greater, and the supervision with which they are favoured is less minute; besides, the cost of maintenance is less than where many varieties of waggons exist on the same line. But whatever may be the upper-works, the under-works of the whole of the waggon stock should be entirely uniform. One of the greatest engineering evils that have been inflicted upon railway companies has arisen from the want of arrangement or consultation between the officers of different lines, in order to consider the question, common to all, as to the best plan and construction of vehicles to be used by them. The result has been, that several companies have built classes of stock unsuited to work conjointly the traffic of their own and other lines. The diversity of practice is no doubt partly occasioned by the growing wants of traffic, and the gradual increase in capacity and tonnage of the carrying stock, incurring unavoidable structural alterations of plan. Amongst the early contributors to the production of the railway waggon were to be found the great carriers, their agents, road-contractors, farmers, builders, wheelwrights, salesmen, graziers, timber merchants, and others whose occupations and opinions, it may be imagined, gave birth to a wide diversity of practice.

Another reason for the want of harmony in past practice has been the separation of the duties of engine and of carriage and waggon superintendence. The carriage superintendent, aiming at the utmost economy of maintenance in his department, has been continually adding to the quantity and weight of material employed in the construction of the carrying stock, as the remedy for the observed failure of weak parts; and thus the stock, particularly waggons, has been increased in strength rather by adding to the mass of matter than by studying to throw the same weight of timber and iron into superior combinations. Doubtless the stock was made very lasting and serviceable, but meantime the heavy trains, handed over to the locomotive department, induced similarly the construction of heavier and more powerful locomotives, when the maximum was quickly reached, and strongly evinced by the sufferings of the permanent way.

It was of course unavoidable, from the need of enlarged

Carriages and Waggons.

dimensions, capacity, and increased strength, both in carriages and waggons, that the dead weight should be to some extent increased. The early first-class carriages weighed 3¼ tons, the bodies or upper parts being 15 feet long, 6 feet 6 inches wide, and 4 feet 9 inches high, in three compartments, to hold six passengers each, or 18 in all. Railway carriages have gradually since been increased in weight to 5½ and 5¾ tons; and in dimension of body to 18 or 20 feet in length, 7 feet 6 inches wide, and 6 feet 3 inches high,—outside measures for the narrow guage. The capacity has been increased from 462 cubic feet in the early carriages to 820 cubic feet. The same increase of dimensions has taken place in the other classes of carriages. The great increase in size and weight of carriages has arisen very much in compliance with the demands of the public for greater convenience, speed, and safety. It was found that the old carriages suffered the most in cases of collision, and it became essential, with the increase of speed and length of trains, to add very much to the size, strength, and weight of the carriages. The wheels weighed originally 17 cwt.: they now weigh from 25 to 30 cwt.

First-class narrow-guage carriages are commonly divided transversely into three compartments, each six feet long, and well lined with cushions; in each compartment there are six seats, and there are in all seats for eighteen passengers. In some instances the seat-partitions or elbow-rests are dispensed with, and the whole width of the compartment thrown open to receive four on each side, or twenty-four passengers in one carriage. Saloon-carriages, having no compartments, are getting into use.

Second-class carriages are usually divided into four compartments, holding eight passengers each, or thirty-two per carriage. They have usually been finished with hard boarding, destitute of cushioning, on the nearly obsolete policy of making them uncomfortable, in the hope of inducing passengers to travel first-class instead. The London and Brighton Railway Company have understood the value of a little encouragement to the public, by meeting them halfway, and supplying comfortably-padded seats in the second class. The receipts in 1858 were materially benefited by the gracious experiment; and other companies must do the same.

Carriages and Waggons.

Third-class carriages do not differ very much from second-class, except that they are thoroughly hard and square inside, older, and more homely.

Passenger brake-vans are made open inside for passengers' luggage; and are formed with a compartment at one end for the guard, with an elevated perch and glazed chamber about the level of the roof, to facilitate his supervision of the whole of the train. The brakes commonly used are sliding-brakes, with blocks of timber applied to the four wheels, brought up by a screw and handle. The weight of the brake-van is from 5 to 6 tons. Horse-boxes are constructed to carry three horses. All narrow-guage carrying stock is placed on four wheels.

Broad-gauge first-class carriages are 24 feet long, 9 feet wide, and 6 feet high in the body, divided into four compartments, holding four passengers on each side, or altogether thirty-two. The second and third-class are 27 feet 2 inches in length; the second-class has five compartments for sixty passengers, and one for luggage; and the third-class has six compartments, for seventy-two passengers and a guard's brake compartment. All carriages are placed on six wheels.

The original form of goods waggons generally employed for some years after the opening of the Liverpool and Manchester Railway in 1829, was simply a platform about 10 feet long on four wheels, with sides varying from 4 to 10 inches in height. Many of these waggons are still employed for the transport of weighty rough goods; they weighed 2½ to 3½ tons, and carried about 2 tons of goods. The general unfitness of this style of waggons led to the adoption of portable sides and ends, which consisted of open crib-rails dropped into staples; and to these were added the costly tarpauling or sheet to cover the goods, and bind them down. (See fig. 64.) The waggon, thus appointed, made 13 or 14 feet in length, and weighing about 3½ tons, was fitted to carry 4 or 5 tons of ordinary goods. But loose or moveable parts of waggons are objectionable, as they occasionally fall away or are lost, or get out of order, and are costly to maintain. The use of tarpaulings is said to have amounted to an annual charge of L.12,000 on one railway. So uncertain is the duration of a tarpauling, that a new one may be spoiled the first day of its use, by injury from projecting angles of goods under cover. Crib-rails and tarpaulings have been to a great extent superseded by built covered waggons, 14 to 16 feet long, with sliding doors and moveable roofs (see fig. 65); so that the crane-chain can deposit or move a bale of goods, however heavy, from any part of the interior of the waggon; and the goods may be perfectly inclosed and protected from damage by fire, wind, or rain.

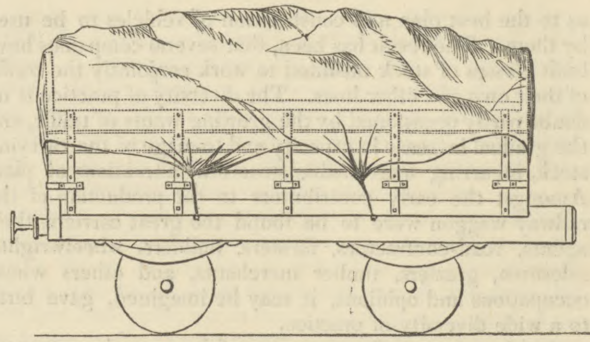

Fig. 64.

Ordinary Open Goods Waggon, loaded and sheeted.

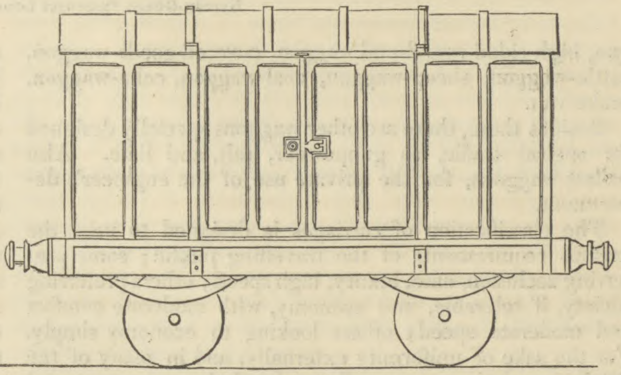

Fig. 65.

Covered Goods Waggon.

Covered waggons weigh from 4 to 5 tons, and can carry, according to their dimensions, 6 to 8 tons. The cost of maintenance of ordinary open waggons is said to amount to from 7 to 10 per cent. of the first cost, as against that of the covered waggons, which is stated to be only 4 per cent.

The Great Northern Railway coal-waggons, which are well designed and constructed, are made with open sides 2½ to 3 feet high, weigh 4 tons empty, and carry 7½ to 9 tons of coal (see fig. 66).

It may be stated generally that properly-made open waggons may carry twice their own weight of goods, and covered waggons 1½ times their own weight of goods; but that ill-designed, heavily-made waggons may carry no more than their own weight in goods. The great demand for weight in waggons arose, as much as from anything else,

Carriages and Waggons.

from the absence of spring-buffers at the ends, and the imperative need of strength to resist the inevitable hard concussions to which they were subject in daily use. To reduce the violence of such contingencies, and also not to add very much to the cost of the waggon, buffing-springs were applied at one end of each waggon, leaving the other end "dead," as shown in fig. 64. The benefits of this partial arrangement became evident; and as at the same time several forms of external buffers—compact, efficient, cheap, and easily applied,—had been matured, and had become regular articles of manufacture, the practice of springing one end of the waggon has been gradually extended in new stock to the other end, as in fig. 65. Waggons, as formerly made, were, in long trains, likewise subjected to violent shocks in starting into motion at stations and otherwise; and therefore the draw-bars also were placed upon springs. Some persons have gone further, and placed the guard or side chains upon springs. Thus the waggon has come to be defended by springs at all points. The substitution of elastic action for dead shocks has proved very beneficial in promoting the durability of waggon stock; and there is no doubt that the extra cost so incurred has been amply compensated in saving of materials and in durability. Spiral springs for buffing and drawing, made of round or of oval steel, have answered very well.

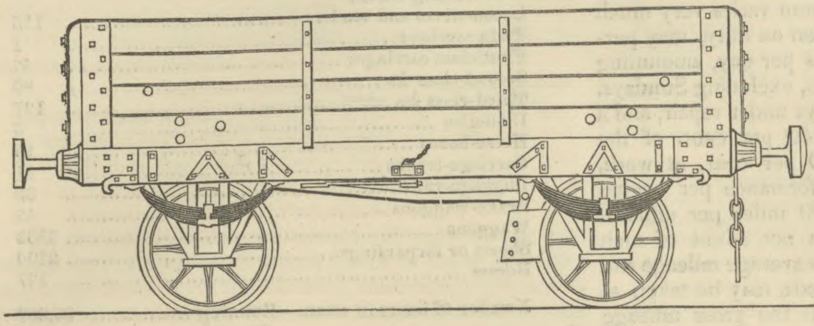

Fig. 66.
Coal Waggon on the Great Northern Railway.

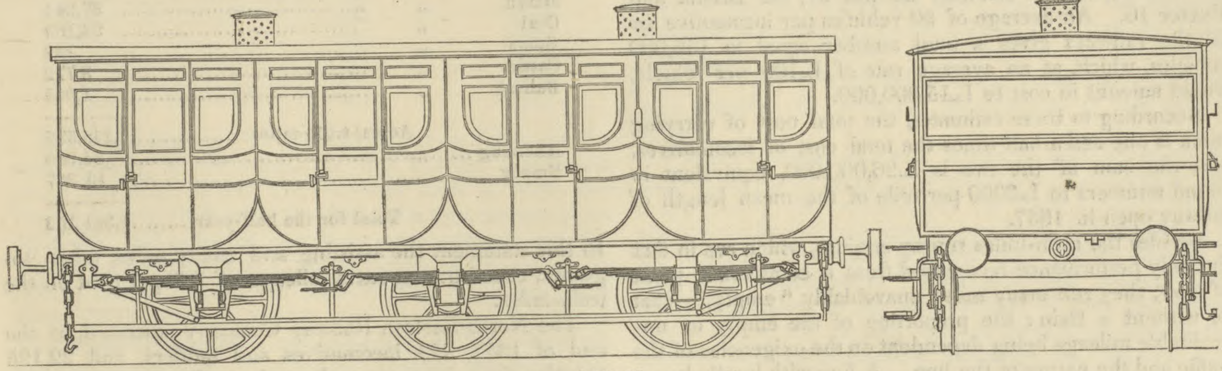

Fig. 67.
Broad-Guage First-Class Carriage.

Broad-guage waggons have been constructed sufficiently strong to carry 20 tons of load. But they are not generally made to carry more than 10 tons. They are carried on six wheels.

An impression of the relative dimensions and bulk of broad and narrow guage carriages may be gathered from the outline elevations of a first-class carriage of each guage (figs. 67 and 68) on the same scale. The relative costs are about L.340, narrow-guage, and L.640, broad-guage. A narrow-guage open goods waggon costs L.80, as compared with a broad-guage waggon costing L.140.

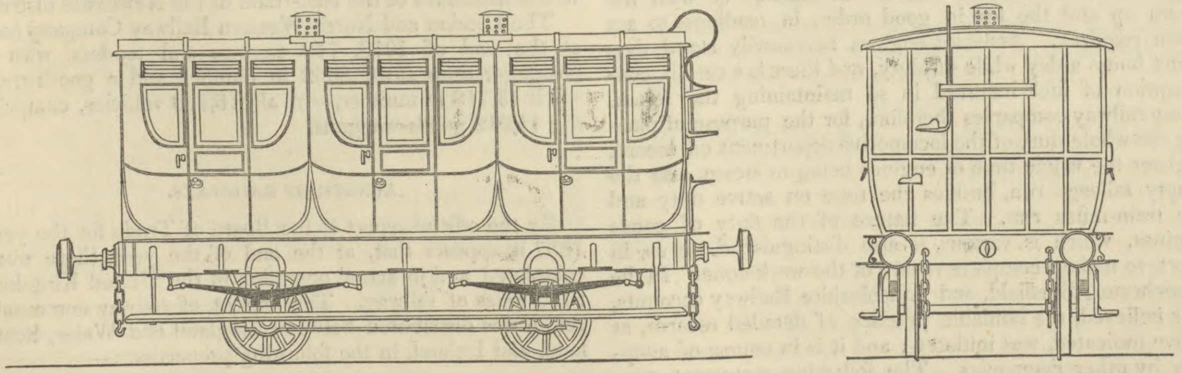

Fig. 68.
Narrow-Guage First-Class Carriage.

Magnitude, Cost, and Mileage of Railway Stock.

TOTAL MAGNITUDE, COST, AND MILEAGE OF RAILWAY STOCK.

The number of miles run per annum varies very much with circumstances. An engine, when on duty, may perform a duty averaging 120 train miles per day, amounting to upwards of 37,000 miles per annum, excluding Sundays. But as a portion of the stock is always under repair, and a portion in reserve, it is safe to allow 50 per cent. of the total number as off duty, leaving 50 per cent. at work, which would reduce the average performance per engine of the whole stock to 18,000 or 20,000 miles per annum. The circumstances of many lines do not admit of such a high average mileage; and the gross average mileage run by each locomotive, passenger and goods, may be taken at 16,000 train miles per annum; and as the gross mileage performed in 1857 amounted to upwards of 83,000,000 train-miles, there would be 5200 locomotives then on stock, which, if they be estimated at an average cost of L.2000 each, would amount in cost to L.10,400,000. The number of vehicles of all classes varies within very wide limits in proportion to the number of locomotives on different railways. The North-Eastern, doing a very large mineral traffic, has probably the largest proportion,—namely, 53 vehicles per locomotive. The Manchester, Sheffield, and Lincolnshire has 38 per locomotive, the Glasgow and South-Western 36, the Great Northern 27½, the Eastern Counties 27, the London, Brighton, and South Coast 25, the Midland 24, the Scottish Central 21, the Bristol and Exeter 16. An average of 30 vehicles per locomotive for all the railways gives a total number equal to 156,000 vehicles, which, at an average rate of L.100 per vehicle, would amount in cost to L.15,600,000.

According to these estimates, the total cost of carrying stock is one and a half times the total cost of locomotives, and the sum of the two is L.26,000,000, equivalent in round numbers to L.3000 per mile of the mean length of railway open in 1857.

Besides the train-miles run by engines, which are in fact the only performance recognised from a commercial point of view, they run many miles unavoidably "empty,"—that is, without a train; the proportion of the empty or unprofitable mileage being dependent on the exigencies of the traffic and the nature of the line. A line with locally heavy gradients must have "assistant" or "pilot" engines in readiness to assist the trains up the inclines, which usually have to return empty to the depot; and in cases of special trains, empty engines are run to or from the train, before or after duty, according to the situation of the engine-depot, as the case may happen.

There is another duty, of a passive description, which is imposed on engines,—to stand "in steam," or with the steam up and the fire in good order, in readiness to act when required. Assistant engines necessarily stand thus many hours a day while on duty, and there is a certain consumption of fuel incurred in so maintaining the steam. Some railway companies therefore, for the purpose of placing the whole duty of the locomotive department on record, register the whole time of engines being in steam, also the empty mileage run, besides the time on active duty and the train-miles run. The nature of the duty of goods engines, which is various, is also distinguished, so as, in short, to make a complete record of the work done. In the Manchester, Sheffield, and Lincolnshire Railway accounts, it is believed, the laudable practice of detailed records, as above indicated, was initiated; and it is in course of adoption by other companies. The following statement contains a list of the rolling stock of that line, and the particulars of the duties performed by the engines during the second half-year 1857; and it may be taken as an example of the proper method of recording such duties:—

Magnitude, Cost, and Mileage of Railway Stock.

Manchester, Sheffield, and Lincolnshire Railway.—Half-year ending December 31, 1857.

List of Rolling Stock,—

Locomotives and tenders	115
Twin carriage	1
First-class carriages	51
Second-class do.	89
Third-class do.	127
Dummies	6
Horse-boxes	19

" "	Standing	28,842
Total hours in steam		173,272

	Cwt.
Coke consumed	241,527
Coal "	229,681
Cost per hour	23·05 pence
" mile	2·45 "

Mileage run by Engines.

		Miles.
Passenger train-miles		693,921
Goods	"	360,243
Mixed	"	87,244
Coal	"	94,189
Stone	"	162
Cattle	"	8,772
Ballast	"	1,045
Actual train-miles		1,245,576
Assisting		34,250
Empty		81,327
Total for the half-year		1,361,153

In this statement the assisting and empty miles, taken together, constitute an extra mileage of 9·3 per cent on the train-miles.

The North-Eastern Railway Company possessed, at the end of 1857, 414 locomotives and tenders, and 22,125 vehicles for passenger and goods traffic, amongst which there were 2321 goods-waggons, 1362 trucks for timber, and 15,073 coal-waggons. The Midland Railway, with 413 locomotives, just one less than on the North-Eastern, had only 9944 vehicles, or less than half the number on the other line, including 8727 waggons; but the Midland waggons are of much larger capacity, as there are amongst the North-Eastern stock 10,050 chaldron-waggons suited to the habitudes of the coal-trade of the Newcastle district.

The London and North-Western Railway Company had, at the end of 1858, 779 engines and tenders, with a passenger-train stock 2552 in number, and a goods-train stock 13,718 in number,—in all, 16,270 vehicles, comprising 11,012 goods-waggons.

LENGTH OF RAILWAYS.

By the official report to the Board of Trade for the year 1857 it appears that, at the end of the year, there were completed and in actual operation in the United Kingdom 9116 miles of railway. This extent of railway communication was distributed between England and Wales, Scotland, and Ireland, in the following proportion:—

	Miles.
England and Wales	6777
Scotland	1269
Ireland	1070
Total	9,116

Railway Employés.

Of the 9116 miles open in 1857, there were only 740 miles of broad guage, and 261 miles of mixed guage; together 1001 miles in England, or 12 per cent. of the whole mileage in England and Scotland.

Of the 9116 miles open in 1857, the following were the lengths of single line:—

	Miles.		Of whole Mileage Opened.
In England and Wales	1715	or	25 per cent.
In Scotland	409	„	32 „
In Ireland	651	„	64 „
Total	2775		30 „

The rate at which the construction of railways has proceeded during the last fourteen years in these countries may be estimated from the following statement, showing the consecutive additions to the gross length of railway, year by year, in the second column, and the total lengths in the third column:—

Year.	Length of Line opened during the Year. Miles.	Total length of Line opened at 31st Dec. Miles.
1843	...	2036
1844	204	2240
1845	296	2536
1846	606	3142
1847	803	3945
1848	1182	5127
1849	869	5996
1850	625	6621
1851	269	6890
1852	446	7336
1853	350	7686
1854	368	8054
1855	243	8297
1856	421	8718
1857	398	9116

It may be observed that, subsequently to 1845, the annual addition to the length of line opened, which was about 300 miles in that year, doubled itself in 1846, and rose to nearly 1200 miles in 1848. During the five years 1846–50, 800 miles of new lines were opened annually. These accelerated rates of construction arose out of the railway mania of 1845–46, when, during these two years alone, 7238 miles of railway were authorized by acts of Parliament to be made. Subsequently to 1850, when the extreme pressure of construction subsided, the annual increase of mileage opened averaged 356 miles per year to the end of 1857; and, according to recent returns, about 340 miles were opened in 1858.

There were 774 miles of railway in course of construction in 1857, not opened in this year; and they make, in addition to the lines already opened, a total of 9890 miles, or nearly 10,000 miles.

RAILWAY EMPLOYÉS.

Upon the lines in course of construction during the ten years 1848–57 the average number of persons employed varied from 63·6 per mile in 1848, and a maximum of 69 per mile in 1849, to 44 persons per mile, or 44,037 persons on 1004 miles in June 1857.

Upon lines open for traffic on the 30th June 1857, in all 8942 miles, 109,660 persons were employed, or 12·26 persons per mile, variously employed, and distributed as in the annexed statement:—

			Per Mile.			Per Mile.
Secretaries or managers	221	or	·024			
Treasurers	26	„	·003			
Superintendents	398	„	·044			
Accountants or cashiers	201	„	·022

Labourers	26,285	„	2·938			
Miscellaneous	2,885	„	·322			
				60,317	or	6·745
Total				109,660	or	12·263

In 1848, 52,688 persons were employed upon 4252 miles, or 12·391 per mile, as against 12·263 per mile in 1857, showing that the total numbers per mile are the same. An analysis of the component elements, however, indicates a proportional reduction in the numbers engaged in the more general services of railways, and an increase in the numbers engaged in the out-door service of the traffic; thus, there were ·364 switchmen per mile in 1857, against ·249 per mile in 1848, showing an increase of nearly one-half more; gatekeepers, ·223 per mile in 1857, against ·094 in 1848, or two and a half times the number; guards or brakesmen, ·415 per mile in 1857, against ·352 in 1848, or one-sixth more. This comparative increase would appear to show that the safe working of the trains has been well provided for with the development of the railway system.

If it be assumed that each employé contributes to the support of two or more other persons, it would appear that 1 per cent. of the population of the United Kingdom was maintained by the railways in operation, independently of the considerable amount of labour employed on railways in course of construction. Mr Stephenson has estimated that, collaterally, in the manufacture of iron, the felling and transport of timber, the production of stores, the erection and improvement of buildings, &c., railways give employment to at least 50,000 men; and that, taking every one together, 2 per cent. of the population derive their maintenance from railways.

Money invested in Railways.

MONEY INVESTED IN RAILWAYS.

On December 31, 1857, the total amount of capital raised for the construction of railways was a small fraction under L.315,000,000 (or L.314,989,626), representing an expenditure of about L.35,000 per mile (or L.34,950). Some small portion of this cost belongs to the lines in course of construction at that date. The money has been raised in the following proportions:—

In 1857.

By ordinary share capital,	L.178,567,935,	or 57 per cent.
By preference shares	58,061,655,	or 18 „
By loans	78,360,236,	or 25 „
Total capital,	L.314,989,826	

Say L.315,000,000.

Average interest on preference shares	4·86	per cent.
Do. do. loans	4·52	„
Do. available dividend on the ordinary share capital	3·60	„
Average percentage of nett receipts to total capital and loans	4·06	„

The relative proportions of ordinary capital, preference capital, and loans above given, have been stationary during the three years 1855, 1856, and 1857; but during the previous six years the proportions of preference and loan

Money invested in Railways.

capital had been increasing from 9 per cent. and 22 per cent. respectively in 1849, to what they have just been stated to be in 1857, namely, 18 per cent. and 25 per cent.

In 1845–6 the dividends of railways appear to have been at their maximum, of which the following are examples:—

Railways.	Dividend on Share Capital in 1846.	
Dublin and Drogheda	4	per cent.
Eastern Counties	6¾	,,
Edinburgh and Glasgow	6	,,
Glasgow and Ayr	7	,,
Great Western	8	,,
Lancashire and Yorkshire	7	,,
London and North-Western	10	,,
London and Brighton	6	,,
London and South-Western	9⅔	,,
Midland	6¼	,,
South Eastern	6⅓	,,
York and North Midland	10	,,
York, Newcastle, and Berwick	9	,,

The precipitate influx of new lines during the four years from 1846 to 1850, the expensive contests before Parliament to prevent such competing lines from being made, the unhappy competitions for the privilege of constructing branch lines, the leasing of new lines by older lines at unremunerating rates, competition for traffic, and other causes leading to great extensions of capital, and arising from the attempts to execute works in three or four years which might advantageously have been spread over twelve or fifteen years,—such causes have been in operation to depress the dividends of railways, and with such power as to reduce the average proportion of nett receipts in 1849 to 2·83 per cent. of the total capital and loans raised at that time. Such, however, is the virtue of railway property that the nett receipts have increased since 1849 from 2·83 per cent. to 4·06 per cent. of the total capital and loans raised in 1857; and notwithstanding the accumulation of preference capital and loans, both taking precedence of ordinary capital, the available dividend on the latter increased from 1·88 per cent. to 3·6 per cent.

The average cost of railways per mile open in 1857 was as follows:—

England and Wales	L.39,275
Scotland	28,225
Ireland	15,664
Total average	L.34,950

—say L.35,000 per mile. But it is worthy of notice that the average cost of independent lines of railway authorized since 1848, and opened for traffic in the course of the ten following years, amounted to only L.11,823 per mile; namely, for England L.14,559; Scotland, L.7243; Ireland, L.7303 per mile. The difference in cost thus exhibited arises, among other causes, partly from the less costly character of the newer lines, and partly from the fact, that the existing lines, which have had no addition to their length for several years, have continually increased their capital. Thus, upon twenty-nine railways, having an aggregate length of 1200 miles, the capital increased from L.39,000,000 in 1853 to L.43,000,000 in 1857, or at the rate of above L.600 per mile per annum. But during the same period the nett receipts of these lines rose from 3·4 per cent. to 4·2 per cent. of the entire capital and loans. In 1849, when a total of 5996 miles had been opened, the total share capital and loans raised was L.229,747,778, or L.38,300 per mile; and as at that time a large proportion of capital was applied to lines in course of construction, this may be accepted as a full mileage cost; whereas, notwithstanding the additional construction of 3120 miles,—half as much again,—at much less mileage cost, the 9116 miles open in 1857 are found to average about L.35,000 per mile, not much less than in 1849, owing to the continual additions made to the capital of the older lines.

Money invested in Railways.

The number of railway companies, and the average length worked by them, was, for 1857, as follows:—

	Number of Companies.	Average Length of Lines in Miles.
England	52	123
Scotland	20	60
Ireland	21	51
Total	93	234

The London and Blackwall Railway, costing L.311,912 per mile, and the North London Railway, costing L.146,320 per mile, stand pre-eminently at the top of the list in capital expenditure per mile, for which their localization in and about London sufficiently accounts. But the third on the list, the Birkenhead, Lancashire, and Cheshire Junction, from Birkenhead to Chester and Warrington, costing upwards of L.75,000 per mile, stands, a beacon and an example to all railway companies, on the battle-ground of the London and North-Western and the Great Western companies. The exalted cost of that line was incurred partly by the protracted contests in which it has been involved with the neighbouring railways, and partly by the costly works of construction joining the railway to the docks at Birkenhead. The principal and older railways have been constructed at a heavy rate of cost per mile, compared generally with the more recent lines; the difference is attributable to the costly legislation and land charges they have incurred, as well as to the magnitude of the works of construction, involving deep cuttings, high embankments, long viaducts and tunnels, in order to obtain the most favourable gradients and curves, conforming, as nearly as possible, to a straight and level course. Of the railways in England, the Carlisle and Silloth Bay, one of the most recently opened, has the honour of standing at the foot of the list, 13 miles long, and costing L.6474 per mile, or little more for the whole line than the cost of a single mile of the Birkenhead, Lancashire, and Cheshire Junction.

Of the Scottish lines, the Caledonian stands at the head of the list, costing L.43,000 per mile; and the East of Fife, 7 miles long, at the foot, costing L.4351 per mile. But the cheapest lines of any length are the Forth and Clyde, costing L.5525 per mile; and the Peebles Railway, costing but L.20 more than that, L.5545 per mile.

Of the Irish lines, the Dublin and Kingston, a suburban line, 8 miles long, cost the highest amount per mile, about L.53,000. The next to it, of any considerable length, is the Ulster Railway, L.25,000 per mile. The cheapest line is the Limerick and Foynes, L.5282 per mile; and this appears to be the cheapest line of considerable length in the United Kingdom.

The proportions of expenditure on capital account cannot, from want of data, be exactly determined. The following may be accepted as an approximate analysis of average cost of the railways open in 1856–7:—

	Per mile.		Per cent.
Law and parliamentary expenses	L.2,000	or	6
Land and compensation	7,000	or	20
Works of construction and stations complete	17,500	or	50
Locomotive and carrying stock	3,000	or	9
Interest on stock, discounts, bonuses, dividends from capital, contingencies, &c.	5,500	or	15
	L.35,000		100

From this statement it would appear that the nett cost of construction and equipment is L.20,500 per mile, or above half of the entire cost; that the cost of land and compensation is L.7000 per mile, or one-fifth of the entire cost per mile. Out of 315 millions of capital, then, it would appear that above 60 millions have been absorbed in charges for land and compensation; of this sum, six-sevenths went intact into the pockets of the landowners, the remainder being dissipated in costs.

PASSENGER TRAFFIC.

The returns forwarded to and printed by the Board of Trade, from which the statistics of traffic are derived, are neither uniform nor complete; and it is difficult to balance the various elements of such returns. The data in many cases can only be approximated to; and they are here presented as nearly correct as is permitted by the nature of the returns. In some instances data are simply reproduced as rendered in the Report of Captain Galton, the secretary to the railway department of the Board of Trade.

The total number of passengers of each class conveyed in 1857 was as follows:—

Countries.	First Class.	Second Class.	Third Class and Parliamentary.	Total, including Miscellaneous.
England	15,671,096	36,603,060	63,562,252	115,858,806
Scotland	1,823,542	2,180,284	10,723,694	14,733,503
Ireland	1,112,188	3,382,941	3,912,183	8,416,579
Total	18,606,826	42,166,285	78,198,129	139,008,888

Note.—There were about 11,000 season or periodical ticket-holders in England, 3000 in Scotland, 4500 in Ireland; in all 18,500, averaging the two half-years.

The proportions were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total.
	Per cent.	Per cent.	Per cent.	
England	13·5	31·6	54·9	100
Scotland	12·5	14·7	72·8	100
Ireland	13·3	40·2	46·5	100
	13·4	30·4	56·2	100

The numbers conveyed per mile of the mean length of railway open in 1857—namely, in England 6610, in Scotland 1226, in Ireland, 1064 miles—were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total, including Miscellaneous.
England	2371	5537	9616	17,527
Scotland	1148	1778	8749	12,017
Ireland	1045	3179	3676	7,909
Total	2090	4737	8786	15,617

The average distances travelled by passengers of each class in 1857 were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total.
	Miles.	Miles.	Miles.	Miles.
England	19·0	13·5	11·7	13·6
Scotland	17·0	9·3	10·7	11·3
Ireland	17·8	12·2	15·2	14·3
Total	18·8	13·8	11·7	13·3

The number and mileage of passenger trains in 1857 were as follows:—

	Total Number.	Total Mileage.	Average Mileage per Train.
England	1,612,357	37,601,375	23·3
Scotland	218,031	3,972,494	18·2
Ireland	135,315	3,263,367	24·1
Total	1,965,703	44,837,236	22·8

The average number of passengers per train in 1857 was as follows:—

	Average Passengers per Train.	Average Mileage travelled by Passengers.	Average Mileage run per Train.
		Miles.	Miles.
England	72	13·6	23·3
Scotland	68	11·3	18·2
Ireland	62	14·3	24·1
Total	71	13·3	22·8

The actual receipts from passengers of each class in 1857 were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total, including Miscellaneous.
	L.	L.	L.	L.
England	2,753,123	3,147,398	2,921,158	9,004,769
Scotland	251,184	178,778	471,432	916,697
Ireland	163,161	248,812	244,628	671,332
Total	3,167,468	3,574,988	3,637,218	10,592,798

The proportions of receipts were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total, including Miscellaneous.
England	30·5	34·9	32·5	100
Scotland	27·4	19·5	51·5	100
Ireland	24·3	37·0	36·4	100
Total	29·9	33·7	34·3	100

Passenger Traffic.

The average receipts in 1857, per mile open, were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total, including Miscellaneous.
	L.	L.	L.	L.
England.........	416	476	442	1362
Scotland.........	204	146	384	746
Ireland	154	234	230	631
Total..........	356	402	409	1191

The receipts per train-mile run are reported to have been as follows:—England, 64·8d.; Scotland, 62·6d.; Ireland, 54·5d.

The average receipts per passenger of each class in 1857 were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total.
	d.	*d.*	*d.*	*d.*
England.........	42·2	20·6	11·0	18·3
Scotland.........	33·1	19·7	10·6	14·7
Ireland..........	35·2	17·6	15·0	18·7
Total	35·5	20·3	11·2	17·9

The average fares per train-mile, of passengers of each class, in 1857, were as follows:—

Countries.	First Class.	Second Class.	Third Class.	Total.
	d.	*d.*	*d.*	*d.*
England.........	2·01	1·41	·87	1·26
Scotland.........	1·77	1·55	·87	1.13
Ireland	1·81	1·35	·90	1·20
Total	1·97	1·41	·87	1·25

From the foregoing statements it appears that the average distance travelled, in 1857, by passengers of all classes, was only 13·3 miles; the greatest average was 19 miles by first-class passengers in England. These figures are suggestive:—they demonstrate that the bulk of the passenger-traffic is local, confined mainly to short distances, and that long journeys, though important, are but secondary sources of income. In 1843, first-class travelling averaged 26 miles per passenger; second-class, 14·4; third-class, 12·5 total, 16·1 miles. The generally lower averages of 1857 are to be ascribed to the extension of short local lines and branches, and to the improved accommodation for second and third class travellers, by which these classes of traffic were promoted. As might be expected, however, on different lines and in different localities the average distances travelled by the different classes vary within considerably wide limits.

The total number of passengers conveyed in 1857 has been seen to be upwards of 139 millions, and the total receipts to be upwards of 10½ millions sterling. Of this large amount of receipts, the third-class traffic, at less than a penny per mile, contributes the most. The first-class receipts are the lowest, and are about 30 per cent. of the entire receipts; the second-class receipts are about 34 per cent., and the third-class about 36 per cent.; and second and third conjointly amount to 70 per cent. of the entire receipts from passengers. It is obvious from these comparative results, that the lower fares pay the best, even with inferior accommodation. The excessive preponderance of third-class receipts in Scotland results partially from the practice of running only first and third class on the Caledonian and the Great North of Scotland railways.

There is a decided preponderance of third-class traffic on the continental railways. In Holland and Prussia the third-class receipts amount to 50 per cent. of the whole; and in France to 43 per cent. On continental lines generally, three-fourths of the passengers are third-class.

Goods Traffic.

GOODS TRAFFIC.

The total quantity of merchandise, minerals, live stock, parcels, &c., conveyed in 1857 are as in the annexed table:—

Heavy Goods Traffic in 1857.

Goods.	England.	Scotland.	Ireland.	Total.
	Tons.	Tons.	Tons.	Tons.
General merchandise	21,138,732	2,909,139	980,056	25,027,927

The proportions of merchandise and minerals carried in each country were as follows:—

Goods.	England.	Scotland.	Ireland.	Total.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
General merchandise	36	26	88·5	35
Coal	39	17	9	35
Unclassed minerals...	25	57	2·5	30
Total minerals...	64	74	11·5	65
Total	100	100	100	100

The weights carried per mile of the mean length of railway open in 1857 were as follows:—

	General Merchandise.	Total Minerals.	Total.
	Tons.	Tons.	Tons.
England (6610 miles).........	3198	5694	8892
Scotland (1226 miles).........	2373	6956	9329
Ireland (1064 miles)..........	920	120	1040
Total (8900 miles).........	2812	5202	8014

The number and mileage of goods trains in 1857 were as follows:—

Goods Traffic.

	Total Number.	Total Mileage.	Average Mileage per Train.
England.........	921,258	32,315,676	35·1
Scotland.........	197,461	5,249,496	26·6
Ireland...........	21,309	1,057,013	49·6
Total......	1,140,028	38,622,185	34·0

The actual receipts from goods-traffic in 1857 were as follows:—

By Goods-Trains.

Countries.	General Merchandise.	Minerals.	Live Stock.	Total.
England	L.6,728,667	L.3,313,256	L.410,267	L.10,452,190
Scotland......	767,297	657,592	47,912	1,472,801
Ireland	285,77[illegible]	16,444	59,177	361,400
Total	L.7,781,743	L.3,987,292	L.517,356	L.12,286,391

By Passenger-Trains.

Countries.	Parcels and Luggage.	Carriages, Horses, and Dogs.	Mails.	Total.
England	L.548,585	L.203,047	L.319,156	L.1,070,788
Scotland	38,128	17,570	56,283	111,981
Ireland.	28,216	16,807	67,628	112,651
Total.....	L.614,929	L.237,424	L.443,067	L.1,295,420

The proportions of the above receipts were as follows:—

By Goods-Trains.

Countries.	General Merchandise.	Minerals.	Live Stock.	Total.
	Per Cent.	Per Cent.	Per Cent.	
England	64	32	4	100
Scotland	52	45	3	100
Ireland	79	4·5	16·5	100
Total.........	63	33	4	100

By Passenger-Trains.

Countries.	Parcels, &c.	Carriages, &c.	Mails.	Total.
	Per Cent.	Per Cent.	Per Cent.	
England	51	19	30	100
Scotland.........	34	16	50	100
Ireland	25	15	60	100
Total.........	48	18	34	100

The average receipts from goods traffic in 1857, per mile open, were as follows:—

	By Goods Trains.	By Passenger Trains.	Total.
England..	L.1581	L.162	L.1743
Scotland	1201	91	1292
Ireland....................	340	106	446
Total...........	L.1380	L.144	L.1524

The receipts per goods train-mile are reported to have been as follows, though it appears from the foregoing figures they should be higher:—

	d.
England	76·6
Scotland	67·0
Ireland	82·6

These statistics of goods-traffic show that upwards of 71 million tons of heavy goods were transported in 1857 in the United Kingdom, two-thirds of which were minerals. But in Scotland the minerals constitute three-fourths of all the heavy goods carried; and the greatest tonnage of goods per mile open is carried in that country. There were upwards of 8½ millions parcels carried on all the railways; and 11 millions of live stock. The total receipts from goods-traffic exceeded 13½ millions sterling; and they stand highest per train-mile in Ireland, probably because the greater part of Irish goods-traffic consists of general merchandise and live stock, which pay better than minerals.

Passenger and Goods Traffic.

PASSENGER AND GOODS TRAFFIC.

The mileage of trains in 1857 was stated to be as follows:—

Countries.	Passengers.	Goods.	Total.
	Train-miles.	Train-miles.	Train-miles.
England	37,601,375	32,315,676	69,917,051
Scotland.............	3,972,494	5,249,496	9,221,990
Ireland	3,263,367	1,057,013	4,320,380
Total.........	44,837,236	38,622,185	83,459,421

The total receipts from all kinds of traffic in 1857 were as follows:—

	Passengers.	Goods.	Total.
England	L.9,004,769	L.11,522,978	L.20,527,747
Scotland............	916,697	1,584,782	2,501,479
Ireland..............	671,332	474,051	1,145,383
Total.........	L.10,592,798	L.13,581,811	L.24,174,609

The following is a general statement of the capital raised, and the gross receipts from passengers and from goods, in 1857, reduced to annual and weekly mileage rates:—

	England.	Scotland.	Ireland.	Total.
Mean length of railway open (miles)..........	6,610	1,226	1,064	8,900
Capital per mile open December 31	L.39,275	L.28,225	L.15,664	L.34,950
Receipts per mile per annum,—				
From passengers......	L.1,362	L.746	L.631	L.1,191
From goods...........	1,743	1,292	446	1,524
Total...............	L.3,105	L.2,038	L.1,077	L.2,715
Receipts per mile per week,—				
From passengers......	L.26	L.14	L.12	L.23
From goods	34	25	9	29
Total...............	L.60	L.39	L.21	L.52
Proportions of receipts—	Per Cent.	Per Cent.	Per Cent.	Per Cent.
From passengers.....	44	37	59	44
From goods	56	63	41	56
Total..............	100	100	100	100
Proportion of gross receipts to capital	7·9	7·2	6·9	7·8

The table shows that the goods is considerably greater than the passenger traffic, the former averaging 56 per cent., and the latter 44 per cent. of the whole receipts. These proportions are identical with those of England alone, whilst they differ widely from those of Scotland and Ireland individually. In Scotland there is much more goods than passenger traffic; in Ireland there is more passenger than goods traffic; whilst the proportions of traffic in England represent the average of Scotland and Ireland together. The gross receipts per mile for England, Scotland, and Ireland are in the ratio of 3, 2, 1; and the total average is L.2715 per mile per annum, or L.52 per mile per week. The goods-receipts are shown to be absolutely greater than the receipts from passengers. This preponderance of goods-receipts has been the growth of years, the increase of goods-traffic having from the first been greater than that

Passenger and Goods Traffic.

of the passenger-traffic. The proportional receipts in 1849 and 1857 may be thus contrasted:—

	1849. Per Cent.	1857. Per Cent.
Passenger receipts	53	44
Goods receipts	47	56
Total	100	100

Working Expenses.

WORKING EXPENSES.

The following table affords a summary of the expenditure of railways, as to the amount of working expenses per mile, per annum, and per train-mile run, as well as the proportion of working expenses, in Great Britain and Ireland, during 1857:—

Working Expenses for the Year 1857.

Countries.	Maintenance of Way.	Locomotive and Carrying Stock.	Traffic Charges.	Miscellaneous, including Police, Watchmen, Compensation, &c.	Rates and Government Duty.	Total.	Corresponding Receipts from Traffic.	Proportion of Expenditure to Receipts.
	L.	L.	L.	L.	L.	L.	L.	Per Cent.
England	1,533,259	3,701,238	2,563,837	1,191,971	717,193	9,707,498	20,195,460	48
Scotland	155,065	444,414	249,986	183,021	61,484	1,093,970	2,486,890	44
Ireland	63,998	190,172	110,381	54,124	20,096 (no duty)	438,771	1,139,296	38
Total	1,752,322	4,335,824	2,924,204	1,429,116	798,773	11,210,239	23,821,646	47
Working Expenses per Mile per Annum.								
	L.	L.	L.	L.	L.	L.

Total	15·5	38·4	26·3	12·7	7·1	100		

Note.—The receipts of such railways as have not made public their working expenses are not included in this table.

The appropriation of the gross receipts to working expenses, interest, and dividend, would therefore be as follows:—

	Per Cent. of Gross Receipts.	
Maintenance of way	7·3	
Locomotive and carrying stock	18 0	
Traffic department	12·4	
Miscellaneous	6·0	
Rates, &c	3·3	
Total working expenses		47
Interest on preference stock and loans		27
Balance available as dividend on ordinary share capital		26
Gross receipts		100

The relative receipts and expenditure per train, as reported, are as follows:—

Receipts.

	Passengers.	Goods.	Total.
	d.	d.	d.
England	64·8	76·6	70·3
Scotland	62·6	67·0	65·0
Ireland	54·5	82·6	60·7

Expenditure.

		Per Cent. of Receipts.	Surplus Receipts.
	d.		d.
England	32·8	48	37·5
Scotland	28·3	44	36·7
Ireland	24·9	38	35·8

Analysis of Locomotive Expenses.—The average cost of locomotive power has been found to be approximately 8¾d. per train-mile, passengers and goods; it is greater for main lines and less for secondary lines. The following are the usual proportions of the locomotive expenditure on principal lines for working, repairs, and renewals:—

	Passenger-Engines per Train-mile.	Goods-Engines per Train-mile.
	d.	*d.*
Wages of enginemen and firemen, cleaning, oil, tallow, water, coking-wages	2·5	2·5
Coke, at 16s. per ton	2·0	4·0
Repairs and renewals, including general charges	4·0	4·5
	8·5	11·0

It will be observed that the element of coke for fuel is a very important item of expense; and as the average cost of coke fit for railway purposes is more than double that of coal, it has become a desideratum to substitute coal for coke, in order to reduce the working expenses of railways. The difficulty hitherto in effecting this desirable object has consisted in the smoke discharged from coal, which is forbidden to be emitted on railways by act of Parliament. There is no doubt of the nuisance of coal-smoke, and of the desirability of extinguishing it; and Mr Joseph Beattie of the London and South-Western Railway has laboured since 1853, with much success, at the problem of smoke prevention on railways. Mr Sylvester Lees and others have followed in his track; and more recently, in 1857, Mr D. K. Clark introduced a method of burning coal without smoke by means of steam-inducted air-currents, delivered into the fire-box above the fuel, and amongst the smoke; a plan which has operated successfully in consuming the smoke, and in promoting the efficiency of the engine. In the course of a few years longer there is no doubt that coke will be generally superseded by coal on railways. By the proper use of coal, half the cost of fuel will be saved, say an average of 1½d. per train-mile, which, upon 83,000,000 miles, would amount to a saving of L.700,000 per annum in the item of fuel alone, and would raise the available dividend on the original capital of railways nearly one-half per cent. (See STEAM-ENGINE.)

THE DEVELOPMENT AND DISTRIBUTION OF TRAFFIC.

The statistics of traffic returns of railways in the United Kingdom, since 1842, indicate a remarkably steady and rapid increase of traffic. In 1842 the total receipts amounted to upwards of L.4,250,000 sterling; in 1852 they were nearly L.16,000,000; and in the five years ending 1857 they were as follows:—

Year.	Average Miles Open.	Gross Receipts.	Receipts per Mile.	Receipts per Mile per Week.
		L.	L.	L.
1853......	7488	18,035,879	2408	46
1854......	7846	20,215,724	2577	49
1855......	8177	21,507,599	2630	51
1856......	8502	23,165,493	2725	52·4
1857.....	8901	24,174,616	2716	52·2

Showing an increase of one-third in the gross receipts since 1853, with an increase of one-fifth in the miles open. The receipts per mile increase, notwithstanding their continual dilution by the infusion of new lines. These results, taken together, indicate the inherent elasticity of the railway system, and its seemingly inexhaustible resources.

As the main trunk-lines constitute the foundation of the railway system, so also those which converge towards and terminate in London—the metropolitan lines—are more important than the provincial lines. The county of Middlesex contained, according to census, in 1851, a population of nearly 2,000,000, or fully one-tenth of the whole population of England and Wales. London is the great heart of the country, and is the chief centre of commerce; and as, moreover, the metropolitan railways, taken together, possess a greater variety of traffic than others, they will be selected as the basis of the subsequent discussions, illustrative of the growing magnitude and distribution of traffic. Now it appears that, on the metropolitan railways, nine in number, including the London and Blackwall and North London, the following were the receipts for the four years ending 1857:—

Year.	Average Miles Open.	Gross Receipts.	Receipts per Mile.	Receipts per Mile per Week.
		L.	L	L.
1854......	2579	9,354,425	3627	70
1855......	2664	9,920,609	3724	72
1856......	2778	10,559,658	3801	73
1857......	2834	10,743,118	3792	73

The metropolitan railway mileage, it may be noted, constitutes one-third of the total mileage, whilst it produces nearly half the whole traffic receipts in the country; insomuch that the receipts per metropolitan mile are two-fifths more than the gross average receipts per mile. Again, it appears that 35 per cent. of the total increase of receipts during the four years 1854–57 was acquired from only 32 per cent. of the average mileage; and but for the baleful competition during 1856–7 between the London and North-Western and Great Northern companies, the proportion of increase would have been more nearly 45 per cent. Whether the increase of receipts be compared with the total increase or with the mileage, the traffic of the metropolitan railways increases the most rapidly, as it is also of the greatest absolute magnitude.

Separating, further, what may be distinguished as the coast lines to the south and east (the Eastern Counties, South-Eastern, Brighton, and South-Western) from the interior lines to the north and west (the London and North-Western, the Great Western, Great Northern, Blackwall, and North London), the receipts of the metropolitan lines may be thus classified and compared with the receipts in other parts of the United Kingdom for 1857:—

	Average Miles Open.	Receipts per Mile per Week in 1857.
Metropolitan interior lines	1515	L.86·5
Metropolitan coast lines	1319	56·5
Other English lines not included in the above	3610	51·5
Scottish railways	1183	40·5
Irish railways	1044	21·0

This comparative statement shows that the densest traffic in England, averaging L.86, 10s. per mile over 1515 miles, lies to the north and west of the metropolis; that the railway traffic of the country is very partially distributed, and that, taking London as the great focus, the traffic radiates and converges in all directions with generally decreasing intensity as the distance from London increases. The northern and western districts, it is true, were in 1857 more freely supplied with railway communication than the southern and eastern districts. But the chief concern of the railway economist is to equalize the flow of the traffic, and, with this design, to provide a sufficiency and suitable localization of converging lines. It is easy to foresee that a third line between London and Oxford, on the narrow guage, occupying the territory between the London and North-Western and Great Western railways, shall be one day constructed as a direct outlet for the densely-crowded

Development and Distribution of Traffic.

traffic of the north-western districts. A railway was in fact projected with this object, and a bill applied for in 1853; but the bill was thrown out under the combined opposition of the neighbouring railway companies,—the opposition of party, with the bugbear cry of injurious competition.

The capacity of a railway for traffic is regulated by the number and weight of the trains, by the speed at which they can be run, by the degree of punctuality of their arrivals and departures at all the stations, and by the length of the line. The number of trains must be limited ultimately by the contingencies of the traffic, and the regularity with which they can be propelled; for the same conditions of safety and expedition which require the use of distinct up and down lines, operate also in limiting the number of trains per day moving in the same direction. A margin must be allowed for unforeseen delays and the want of absolute punctuality; and therefore some fixed intervals must be adopted as the minimum period of time which can be interposed between the starting of successive trains from a terminus.

The weight of the trains is another important element, and it is one which has been overlooked in the economy of railways. Heavy trains demand heavy engines, capable of drawing heavy loads and of keeping time. Now heavy engines at high speeds operate most injuriously upon the road, and so seriously as to have made it a matter of certain experience that the economical limits of engine-weight has on some lines been exceeded. The more nearly the speeds of trains can be approximated, the higher may the speeds be, and the greater the number which may be run, though of course the probability of accidents by collision or otherwise, at the higher speeds, is increased by unforeseen causes of irregularity. The reason is obvious; fast trains are not so shortly brought up as slow trains, and collisions are greatly more disastrous. The length of line also affects the capacity for traffic, as the contingencies of transit increase in proportion with the length; and the daily number of through trains should be less. The shorter the lines in general, the more frequent are the trains. Great and continuous length of line is then, so far, an element of weakness, as much of the traffic on every section of a long line depends upon the arrivals from other parts; and its safe and beneficial working must depend all the more upon the aid of the telegraph.

The traffic of the London and North-Western Railway affords ample illustration of the foregoing doctrine. The main line was partially opened in 1837, and in 1838 it was opened through. The traffic of this line sprang up from very small dimensions in 1837, and rapidly developed, as may be observed in the following historical summaries of the traffic. The daily numbers of trains to and from the principal termini or stations of different sections of the line, at successive intervals of years, were as follows:—

Railways.	1837.	1848.	1852.	1857.
	No.	No.	No.	No.
London (Euston)	19	44	86	109 trains.
Stafford	14	38	104	... „
Manchester	(1831.) 26	90	102	... „
Total...............	59	172	292	109 „

The average weight of engines working these trains varied from 7 tons in 1831, to 18 or 19 tons in 1848. In 1852 the weight of engines, with tenders, averaged 36 tons at Euston, 28 tons at Stafford, and 32 tons at Manchester; and in 1857 the average of engine and tender rose to about 40 tons at Euston. The running speed of goods trains averaged from 10 miles per hour in 1831 to 20 miles per hour in 1848–57. The average weight of trains, without engine and tender, was as follows:—

Development and Distribution of Traffic.

Railways.	Trains.	1837.	1848.		1852.	1857.
		Tons.	Tons.		Tons.	Tons.
London	Passenger.........	46	57	72	87	140
	Goods	112	141			
Stafford	Passenger.........	45	53	66	75	...
	Goods	118	159			
Manchester...	Passenger.........	(1831.) 11	55	58	64	...
	Goods...............	45	111			

These data show a great increase both in number and in weight of trains at all the stations;—from 172 trains per day in 1848, to 292 trains per day in 1852. Taking London trains for special analysis, there went into and out of Euston station 44 trains daily, averaging 72 tons weight, in 1848; 109 trains daily, averaging 140 tons weight, in 1857;—showing an increase to two and a half times the number, and to double the weight; or, upon the whole, to five times the magnitude of the London traffic, as it was in 1848, during the subsequent period of nine years. This appears an overwhelming rate of progress; and it looks still more formidable when it is considered that, into and out of London, during the period from 1848 to 1852, the daily number of trains increased 10·5 per cent. per annum; 1852–57, 4·6: the weight per train increased, 1848–52, 4 tons; 1852–57, 11 tons: the whole train weight increased, 1848–52, about 1000 tons; 1852–57, 1500 tons per annum.

This statement plainly indicates that in the earlier stages of development, whilst yet the line was free and unburdened with business, the number of trains was freely increased to conduct the growing traffic, with a small increase in their weight; but that subsequently, as the line became crowded with trains, and the circulation of traffic embarrassed, the number of trains was much more slowly increased, whilst considerable additions were made to their weight; so much so, that the whole train-weight, indicating the general magnitude of the traffic, has increased in an accelerating ratio since 1848.

So early as 1849 the question of heavy engines and high speeds, incidental to the crowded traffic of the London and North-Western Railway, was one of considerable embarrassment in its engineering aspects. The effects on the rails and other parts of the permanent way, produced by the increased weight and speed of the engines and trains, had become very marked, and the deterioration of the road had increased very rapidly under the heavy engines introduced; and further, the immediate damage to both the road and the rolling stock, from high speed, outweighed, in positive loss to the company, the additional fare received. To remedy this state of affairs, it was proposed to reduce the number of passenger-trains, augmenting their weight and diminishing their speed, in order to give more scope for the working of the heavy goods-trains, which were often obliged, even at that time, to be taken at speeds of 25 to 30 miles per hour, though timed for 20 miles an hour. In dealing with the passenger traffic, it was proposed by the general manager to use the lighter class of engines for short local trains, and on branch lines to run fewer carriages with trains, by causing passengers to change their seats at junction instead of attaching the carriage itself; in connection with which it was found that the average capacity and actual number of passengers in the carriages, in 1848–9, were as follow:—

	Capacity for Passengers.	Average Number of Passengers per Carriage.
First class....................................	18	7
Second class	25	13
Third class	32	21

Development and Distribution of Traffic.

It was obviously considered in 1849, that at that time the natural limits of the traffic of the London and North-Western Railway were, if not exceeded, at least, under the circumstances, fully attained.

Nevertheless, in 1853, as compared with 1849, the engine-mileage increased 16 per cent., merchandise and mineral tonnage 56 per cent., train-weight 33 per cent., and engine-weight practically 10 per cent., on the lines open in 1848. To provide for the working of this largely-increased traffic, many of the lighter engines were condemned as unfit for the purpose, and were replaced by heavier engines. *Secondly*, The road was made much stronger, with heavier rails and chairs, larger sleepers, deeper ballast, and better drainage. But the damage to the road, and cost of maintenance, notwithstanding its greater strength, has unavoidably increased; and it was estimated that in 1853 the "life" of the rails was reduced from 20 years to 15 years. *Thirdly*, The electric telegraph was extensively introduced over the line, the use of which greatly facilitated and economized the working of the traffic, and practically doubled the capacity of the railway for traffic.

In 1856 an extension of the system of telegraphic signalling, by detail sections, was applied and in operation over the entire distance from London to Rugby, 83 miles,—the section of greatest traffic,—upon a plan which was considered by Captain Huish in 1858, after two years' experience of its working, to be the nearest to perfection that could be arranged. A signal apparatus was stationed every 2½ miles on the whole distance; and every train as it comes upon a fresh length of 2½ miles is telegraphed forward to the next station in the series, and when it leaves that length its passage forward is telegraphed back to the station behind. By this means they have the power of preventing trains being within 2½ miles of each other, be their speed or irregularity what it may. This system of communication has conduced very materially to the safety of the line, and it inspires great confidence into the men whose duty it is to work the traffic. During fog, the telegraph apparatus is of inestimable utility, in conjunction with the use of fog-signals, which are fixed to the rails, and discharged with a loud report by the engine in passing over them. Captain Huish mentions that, during two days of such intense fog that a train could not be seen at the distance of its own length, 400 trains were run, without diminishing the speed, by the aid of the signals, and without accident. It was like a discharge of platoon firing from one end of the line to the other. In view of the formidable and increasing traffic, a third line of rails was in 1858 commenced to be laid down from London, for a distance of 54 miles, for the running of the goods and mineral trains, at slower and more economical speeds, without interfering with the rapid trains of the main line; and it was anticipated that the saving of tear and wear, by diminished speed, and the saving of shunting and delaying slow trains to let the fast trains pass, would pay the interest of the cost of the third line. There can be no doubt of the sound policy of this course.

Meantime, the pressure exerted upon the resources of the railway by the mixing of slow with fast trains, has driven the London and North-Western Railway Company to the expedient of working the majority of their slow or goods trains during the night, when the road is comparatively clear. Thus, the average number of passenger and of goods trains on the southern division, that passed Tring station, 32 miles from London, during the twenty-four hours, in April 1857, was as follows:—

	Passenger Trains. No.	Goods Trains. No.	Total Trains. No.
6 A.M. to 12 noon	16·2	7	23·2
12 noon to 6 P.M.	18·4	10·4	28·8
6 P.M. to 12 midnight	11	13·4	24·4
12 midnight to 6 A.M.	2	26·2	28·2
Day's total (specials extra)	47·6	57·0	104·6

Showing that the greater number are goods trains; that 26 goods trains, or nearly half their whole number, were run after midnight; and that the busiest periods of the 24 hours were after mid-day and after midnight, so equally and unavoidably was the traffic distributed over the day and night: the stupendous machine being in ceaseless operation, working double turns. The greatest average number of passing trains, about five per hour, indicates an arrival at average intervals of 12 minutes, or 24 minutes interval each way, up and down. This appears a fair allowance of time, but it conceals the inequalities of speed and the unpunctualities of slow and fast trains. It was found, in the course of one week's observation at Tring station, that there were, in the arrivals of passenger-trains alone:—*Up-trains*, 18 arrivals behind time 5 minutes and upwards,—maximum lateness 34 minutes; *down-trains*, 29 arrivals behind time 5 minutes and upwards,—maximum lateness 16 minutes; in all, 47 late arrivals, or 8 per day;—being at the rate of one late arrival in six passenger trains, independently of the irregularities of goods trains. It is superfluous to dwell on the highly-disciplined organization which is demanded to insure the safe working of traffic so complicated and of such magnitude.

Such is, in brief, the material history of the most hardly-worked line in the kingdom,—a "representative" line—developing the successive stages of a growing traffic, and the successive contrivances and organizations to provide for it.

RAILWAY SPEEDS AND LOCOMOTIVE PERFORMANCES.

Railway Speeds and Locomotive Performances.

"Railway speed" is a variable quantity, varying in the same country, and different in different countries, according to the amount of business done and the relative value of time. The cost of transport is affected by the element of speed more, perhaps, than by any other condition:—the actual tractive force of engine necessary to draw a given train increases much faster than the ratio of the speed simply. At the higher speeds it increases nearly as the square of the speed. Thus, if an engine and tender, weighing together 32 tons, and exerting a given tractive force, takes, say, forty loaded carriages, weighing 290 tons, at 20 miles per hour on a level, the loads which it could take if it exerted the same tractive force at higher speeds, would be only as follows:—

On a Level.

At 20 miles per hour,	40 carriages,	weighing 290 tons.
„ 30 „ „	30 „	„ 220 „
„ 40 „ „	21 „	„ 160 „
„ 50 „ „	15 „	„ 115 „
„ 60 „ „	11 „	„ 85 „
„ 70 „ „	8 „	„ 60 „

The influence of gradients, also, is very important. If an engine and tender, weighing together 32 tons, be capable of drawing a maximum train of, say, 56 loaded carriages, weighing 420 tons, at 20 miles per hour on a level, it would only draw the following loads, at the same speed, on the following inclines:—

At 20 Miles per Hour.

Level..............	56 carriages,	weighing 420 tons.
Incline 1 in 600,	45 „	„ 340 „
„ 1 in 300,	36 „	„ 270 „
„ 1 in 150,	27 „	„ 200 „
„ 1 in 100,	20 „	„ 150 „
„ 1 in 75,	16 „	„ 120 „
„ 1 in 50,	12 „	„ 90 „
„ 1 in 40,	9 „	„ 65 „
„ 1 in 30,	6 „	„ 45 „
„ 1 in 20,	3 „	„ 24 „
„ 1 in 10,	*nil* „	„ *nil* „

It is here shown that, on an incline of 1 in 20, the engine would only be capable of taking up three loaded carriages, about 24 tons weight, and that on 1 in 10 its whole power

Railway Speeds and Locomotive Performances.

in this particular case would be absorbed in pulling up its own weight. Hence the prime importance, in the early stages of railway experience, of constructing the gradients as nearly level as was practicable, as they absorbed, according to their steepness, large proportions of the power of the light engines of the time, in ascending hills; and that which would otherwise appear unwarrantable—the costly construction of the early railways by expensive tunnelling, viaducts, bridges, and cuttings, to approximate to the desiderated horizontal standard—is abundantly explained by the paramount necessity of usefully employing the limited power of the engines then constructed. This was the stand-point of the elder Stephenson; he maintained the superiority of "flat" gradients, and the sound policy of incurring a large expenditure in construction in order to avoid otherwise heavy inclines and heavy expenses. The ruling gradient of the Liverpool and Manchester Railway was fixed at 1 in 900, excepting of course the inevitable inclines at Rainhill summit, for working which special provision was made; that of the next great line, the London and Birmingham, was fixed at 1 in 330; and it is well known at what cost even this gradient, though considerably steeper than the Liverpool and Manchester, was obtained. It was the object of Mr Stephenson to make this railway as mechanically perfect as possible, reducing the gradients to the minimum consistent with the conformation of the country. On the Great Western Railway, one of the earliest made lines, the ruling inclination is 1 in 1320 for the greater part of the way. Mr Joseph Locke initiated the system of cheaply-constructed railways, as the facilities for increasing the power of locomotives became better understood; he constructed lines with long steep gradients, some of them 1 in 70, 1 in 75, 1 in 80. The Great Northern Railway, of comparatively recent origin, is constructed on a ruling gradient of 1 in 200; and in general the more recently made lines have the steepest gradients. Following thus the variable surface of the country, this system became known as the "undulating system," and it has even been deemed preferable to the system of perfect or approximate levels, being supposed to afford breathing intervals, as was thoroughly understood in coach-driving, when the horses were eased by "getting the shoulder off the collar" going down-hill. The analogy is not sound; an engine never tires, and its power does not necessarily fluctuate like horses' power. The question of levels *versus* gradients appears to involve the question of straight lines *versus* curves; for, inasmuch as steep railways are generally also lines of frequent curves, which by common consent operate very prejudicially in absorbing locomotive power, the question is rather as between gradients and curves on the one part, and levels and straight lines on the other part. Moreover, the ruling speeds, as they may be called, have in the course of years increased. The question is not susceptible of a comprehensive and satisfactory solution otherwise than by means of a comparative analysis of all the elements of working expenses during a series of years.

Working Speeds of Passenger-Trains.—The average speed of express trains, including stoppages, varies from 36 to 42 miles per hour; and of parliamentary trains, stopping at all the stations, the average speed, including stoppages, varies from 17 to 21 miles per hour. The speeds of ordinary trains are intermediate between those of express and parliamentary trains, dependent on the frequency of the stoppages.

If the delays incurred by stoppages be allowed for in bringing up express trains, and in getting up the speed, for which four minutes per stoppage may be allowed, and also the time standing at stations, the average speed while running with steam on, would vary from 42 to 48 miles per hour. The following are the comparative speeds of express trains on the broad and narrow guages in 1859:—

Railway Speeds and Locomotive Performances.

	Average Speed, including Stoppages.	Average full Speed while Running.	Maximum Speed in Practice.
	Miles per Hour.	Miles per Hour.	Miles per Hour.
BROAD GUAGE—			
London and Birmingham	42	...	...
Average	37	45	About 60
NARROW GUAGE—			
London and Brighton	40·4	...	...
Average	38·5	45	About 60

The average full speed on the Great Northern Railway (narrow guage) is 47 miles per hour, and a speed of 62 miles per hour is frequently run. During periods of active competition the trains on the Great Western Railway (broad guage) have been run at a speed of 65 miles per hour. But, such a high speed can only be run, with any pretension to safety, on the best parts of the lines, free of curves, and with the road in first-rate order. The average practice in speeds of passenger-trains appears to be the same on the broad and the narrow guages.

Working Speeds of Goods Trains.—The ordinary average progress of goods-trains, including all detentions, varies from 10 to 18 miles per hour over long distances. The ordinary actual speed while running varies from 15 to 25 miles per hour; 20 miles per hour is a common running speed. The very large goods-traffic of the London and North-Western and Great Northern Railways is conducted at higher than average speeds, in order to clear the passenger traffic—15 to 20 miles per hour, including stoppages, and frequently at a running speed of 30 to 35 miles per hour, or occasionally 40 miles per hour when the stoppages are long.

Locomotive Performances.—The duty and performance of locomotive engines vary materially, as may be supposed, on different lines, according to the nature and extent of the traffic. The following are a few characteristic performances on different railways.

London and North-Western Railway, southern division. The principal passenger trains have been classified thus:—

Description of Train.	Number of Carriages.	Train Weight.	Running Speed.	Number of Stoppages.
		Tons.	Miles per Hour.	
1. Express	9	46	42	3
2. Day mail	13	66	38	5
3. Night mail	17	86	34	7
4. Stopping train	21	106	31	9
5. Heavy stopping train	25	126	28	11
6. Extra train	34	171	36	5

The average speed, including stoppages, and the consumption of coke per mile run, are as follows:—

	Average Speed.	Consumption of Coke per Mile run.
	Miles per Hour.	lb.
1. Express	39	21
2. Day mail	33	30·6
3. Night mail	31	26·6
4. Stopping train	27	30·6
5. Heavy stopping train	26	29·2
6. Extra train	33	42·3

Goods-trains have been run from Rugby to London (81½ miles) with the following results:—

	1st Goods Train.	2d Goods Train.
Number of waggons	53	45
Train weight (tons)	450	402
Running speed (miles per hour)	17	17
Number of stoppages	10	10

The average speeds, including stoppages, and the consumption of coke, were as follows:—

Accidents on Railways.

	Average Speed. Miles per Hour.	Consumption of Coke. lb.
1st goods train	12	71·4
2d ,, ,,	14	54·2

The coal-trains on the London and North-Western, Midland, and Great Northern railways, are generally made up of 30 to 35 waggons, carrying each 6 or 7 tons of coal, or a total load of 200 to 240 tons coal, amounting to a total train-weight of 400 tons. This train is taken by a six-wheel coupled goods-engine, with two steam-cylinders, 16 inches diameter, and 24 inches stroke, and 5 feet wheels, weighing 30 to 32 tons, with a tender 13 to 15 tons. The gross weight of engine, tender, and train, is therefore about 445 tons, which ascends inclines of 1 in 200 at a speed of 10 to 15 miles per hour, and travels the entire route to the metropolis, including stoppages, at a speed of 18 miles per hour. The steam-pressure in the boiler is usually 120 lb. per square inch; but on the Great Northern Railway 140 lb. steam is employed in the goods-engines, and they can take a train of 40 loaded waggons, carrying 290 tons of coal, weighing altogether 455 tons, or, with engine and tender, 500 tons gross, up an incline of 1 in 178 at 10 miles per hour, and otherwise perform the whole journey in good time.

The Lickey incline of the Birmingham and Gloucester line is 2⅛ miles in length; gradient, 1 in 37. A tank-engine, with cylinders 17 inches diameter and 24 inches stroke, with 4 feet 4 inch coupled wheels, can take a train-weight of 134 tons, or a total gross weight, including the engine, of 168 tons, at 8 miles per hour. The exertion of engine-power to perform this duty would be equal to the traction of a gross weight of seven times the amount, or nearly 1200 tons, on a level.

The Kittybrewster incline, on the Great North of Scotland Railway at Aberdeen, is made on a gradient of 1 in 59, with quick curves, and about 2 miles long. A tank-engine, with cylinders 15 inches diameter and 24 inches stroke, and four 4½-feet coupled wheels, weighing 25 tons, can take up a train-weight of 200 tons at 10 miles per hour, equivalent to a gross weight of 900 tons on a level.

But perhaps the most extraordinary example of a dead pull by one engine is to be seen on the Vale of Neath Railway, broad guage, with a gradient of 1 in 90, worked by a six-wheel coupled tank-engine weighing 40 tons, with cylinders 17 inches diameter and 24 inches stroke, wheels 4 feet 9 inches diameter. This engine can take up the incline, 1 in 90, a train of 25 loaded waggons, 15 tons each, or 375 tons total, and, with the engine, 415 tons gross,—equivalent to a gross weight of 1245 tons on a level.

A goods-engine, working at full power, exerts a tractive force of 10,000 to 12,000 lb., or about 5 tons pull on the train; so that a pull of 5 tons from the engine suffices to draw behind it 1000 tons on a level.

A tractive force of 10 or 12 lb. is capable of drawing 1 ton on a level at 10 miles per hour. At 60 miles per hour the required tractive force is about 45 lb. for 1 ton of gross weight.

ACCIDENTS ON RAILWAYS.

The question of railway accidents involves the whole question of railway management in detail. Accidents may be called the weak points of the system, where imperfection is manifested, where failure crops out, and where the line of demarcation may be drawn between the practicable and the impracticable. "If the road is perfect," says Captain Huish, "if the engine is perfect, if the carriages are perfect, and I will go on to say, if the signalman is perfect, and if everything about the railway is perfect, almost any amount of speed that can be got out of an engine may be done with safety. But we deal not with theoretical excellence, but with practical facts, and none of these things are perfect; and in a large machine like a railway they cannot always be kept perfect." "The question of railway communication," he adds, "divides itself into two great parts:—there is the great commercial principle involved, there is the great public principle of safety and convenience." The adjustment of the claims of the proprietors, who look for a return for their money on the one part, and the claims of the public looking for increased accommodation on the other part,—this is an expression of the whole question, and involves of course the consideration of railway accidents.

Accidents on Railways.

Safety to life and limb is of course the most important consideration in the working of railway traffic. Yet the problem is substantially this:—there are upwards of 140 millions of passengers and 70 million tons of goods per annum conveyed over our railways; assumed that all these must be transported by railway, what is the best way to do it? It must at the best be by a species of compromise; there must be a limit to tentative measures, there must be a risk. "If you do not go at all," says Mr Seymour Clarke, "there is no risk of an accident; if you go one mile an hour it is more risky than if you stand still; it is a natural attendant upon all travelling that there is a liability to accident of some sort." And, again, Mr Locke thinks "that where you have the certainty of inflicting an inconvenience on the public by a prospective advantage in the saving of an accident, you should be very careful how you entail a perpetually recurring inconvenience for the sake of preventing an accident which may never arise."

The evidence adduced before the select committee of the House of Commons on railway accidents in 1858, from which the foregoing extracts have been made, has led the committee to the conclusion, that accidents on railways arise from three causes:—inattention of servants; defective material, either in the works or the rolling stock; and excessive speed. Of the accidents reported to the Board of Trade that happened in 1857, there appears to have been twice as many by collision between trains as by running off the rails; and of the accidents by collision, five-sixths took place between passenger-trains and goods-trains; and only about one-sixth between passenger-trains, one against another. It further appears that a very small proportion, not above one in twenty, of the accidents reported, have directly arisen from excessive speed, but in every case in conjunction with imperfections in the permanent way. It may be observed that the greater proportion, if not all of these accidents, may be traced primarily to the crowding of trains, timed for unequal speeds, and the want of punctuality, which involve the risk of every kind of accident as a consequence:—by a want of perfect manifestation or apprehension of signals, or by excessive speeds. As tentative measures, the free use of the electric telegraph for giving intelligence of the exact relative positions and circumstances of trains on the line, and the use of the most powerful brakes for bringing up the trains in the shortest practicable distance, are probably of the most urgent necessity. The admirable utility of the road-telegraph is undisputed; and Captain Galton adduces some remarkable illustrations of its beneficial operation in the entire prevention of accidents by collision on lines where it is thoroughly enforced, and where previously to its use such accidents were incurred. Perfect brakes are also indisputably promotive of safety in working traffic and in compensating for unavoidable irregularities. With the usual amount of braking power, a train at 50 miles per hour may not be stopped within 900 or 1200 yards. An instantaneous brake is not of course what is wanted; on the contrary, a length of 200 yards appears to be the shortest desirable space within which a train at 50 or 60 miles per hour should be stopped, so that the process of retardation should not be accompanied by the risk of carriages over-riding each other, or of violence to the passengers; and this appears to have been accomplished on the Lancashire lines by Newall's and by Fay's brake; Chambers' and Champion's brake, applied to a series of carriages in a train, has been proved to be serviceable and efficient on the North London Railway, where it is employed in working the traffic of that line, than which there is not a more hardly-wrought line in the kingdom, in its special character of an omnibus line, with stations averaging a mile apart, at which all the trains are stopped, the journey being run at an average speed of 16¼ miles per hour, including stoppages. There are other very powerful systems of train-brakes in operation. Steam-brakes applied to the locomotives and extended to the tenders, and even to the brake-vans, have been found beneficial, and capable of stopping a train within half the usual distance.

The general adoption of a simple method of communication between the guard and the driver of a train in motion is a desideratum. There are various plans obvious and sufficient enough, but it would appear that, to insure their adoption by all railway companies, legislative interference must be invoked.

RAILWAY LEGISLATION.

Since Parliament began to legislate for railways, a multitude of laws have been placed upon the statute-book, which will certainly excite the wonder, if they fail to be the admiration, of future generations. The London and North-Western Railway alone is regulated by nearly two hundred different acts! Not only are the statutes numerous; they are irreconcileable in principle and detail. Several different select committees have, at various times, deliberately reported against the possibility of maintaining competition between railways, and to this principle Parliament has as often assented. Yet, the practical operation of the laws which have received legislative sanction has been throughout, and at the same time, to negative this principle, by almost invariably allowing competition to be obtained wherever it has been sought. Whatever may have been the effect for the time, the competition which Parliament permitted has generally been terminated by combination. As Mr Stephenson puts it:—"Where combination is possible, competition is impossible."

The expenses, direct and incidental, of obtaining an act of Parliament have been in many cases enormous, and generally are excessive. There are three parties responsible for such extravagance,—Parliament itself, the railway companies, and the landowners. In 1855, it was shown, by a return of Mr Hadfield, which was, however, far from complete, that the amount expended by existing railway companies in obtaining the acts of Parliament by which they are incorporated was no less, in parliamentary, legal, and engineering costs, than fourteen millions sterling! The adherence to useless and expensive forms by parliamentary committees, in what are called the standing orders, or general regulations for the observance of promoters of railway bills, on the one part, and the itching for opposition of railway companies, to resist fancied inroads on vested rights, and supposed injurious competition, on the other part, have been amongst the chief sources of excessive expenditure. By a return of Colonel Wilson Patten, in 1859, it was shown that the parliamentary expenses alone, incurred by railway companies owning L.263,000,000 capital, amounted to about 8½ millions sterling, or 3·2 per cent. Mr Stephenson mentions an instance showing how Parliament has entailed expense upon railway companies by the system complained of. The Trent Valley Railway was, under other titles, originally proposed in 1836. It was, however, thrown out by the standing orders committee, in consequence of a barn, of the value of L.10, which was shown upon the general plan, not having been exhibited upon an enlarged sheet. In 1840, the line again went before Parliament. It was opposed by the Grand Junction Railway Company, now part of the London and North-Western. No less than 450 allegations were made against it before the standing orders sub-committee, which was engaged twenty-two days in considering those objections. They ultimately reported that four or five of the allegations were proved, but the committee nevertheless allowed the bill to proceed. It was read a second time and then went into committee, by whom it was under consideration for sixty-three days; and ultimately Parliament was prorogued before the report could be made. Such were the delays and consequent expenses which the forms of the House occasioned in this case, that it may be doubted if the ultimate cost of constructing the whole line was very much more than the amount expended in obtaining permission from Parliament to make it. This example serves to show the expensive formalities, the delays, and difficulties, with which Parliament surround railway legislation. Another instance, quoted by the same authority, will show not only the absurdity of the system of legislation, but also the afflicting spirit of competition and opposition with which railway bills are canvassed in Parliament, and the expensive outlay incurred by companies themselves.

In 1845, a bill for a line now existing went before Parliament, with eighteen competitors, each party relying on the wisdom of Parliament to allow their bill at least to pass a second reading! Nineteen different parties condemned to one scene of contentious litigation! They each and all had to pay not only the costs of promoting their own line, but also the costs of opposing eighteen other bills. And yet, conscious as government must have been of this fact, Parliament deliberately abandoned the only step it ever took on any occasion of subjecting railway projects to investigation by a preliminary tribunal. Parliamentary committees generally satisfied themselves with looking on and watching the ruinous game of competition for which the public are ultimately to pay. In fact, railway legislation became a mere scramble, conducted on no system or principle. Schemes of sound character were allowed to be defeated on merely technical grounds, and others of very inferior character were sanctioned by public act, after enormous parliamentary expenses had been incurred. Competing lines were granted,—sometimes parallel lines through the same district, and between the same towns.

The following are the costs incurred in obtaining the original acts of some of the older railway companies:—

Great Western Railway act	L.88,710
London and Birmingham act	72,868
Eastern Counties act	45,190

It is not, of course, to be ignored that the parliamentary agents and the general body of lawyers—solicitors, conveyancers, and council—concerned in railway enterprise, get up and carry out new lines and branches as a matter of business, and that they necessarily profit by the complications and delays incidental to parliamentary routine. It has been found that in past years legal and parliamentary expenses have varied from L.650 to L.3000 per mile. In one contest, L.57,000 was spent amongst six counsel and twenty solicitors. The sum expended by one company alone in nine years, in legal and parliamentary expenses, had reached L.480,000, averaging L.53,300 a year. Notwithstanding the greatly diminished cost of railway-making in more recent times, the average capital expenditure on railways has, as formerly observed, been nearly maintained, by otherwise excessive expenses, at the same high rate,—having amounted in the end of 1857 to L.35,000 per mile.

But the expenses incurred through the opposition of railway companies amongst themselves, influenced by the bugbear competition, are indeed secondary to the charges for land and compensation. Parliament affords extraordinary facilities to landowners to make extraordinary demands for compensation. Having given them these facilities, it then makes the legal steps by which such demands can be resisted so expensive that it is frequently difficult to decide whether, if all the desired reductions can be made, the cost of obtaining the saving will not exceed the whole amount that can be saved. And yet it is well known that, except in regard to houses actually demolished, nearly every piece of property which is intersected undergoes improvement in value, in consequence of the construction of the lines. In towns and villages the land abutting on railways becomes valuable as frontage; and at country stations the land becomes desirable for building purposes. The millions which have been paid by railway companies to landowners may be fairly said to be so much put into their pockets as an inducement to allow their property to be increased in value. "Once the greatest obstacles to railway enterprise," says a writer in the *Edinburgh Review*, "owners of estates have of late years been amongst its chief promoters. Since the Liverpool and Manchester line was first defeated by landed opposition, and succeeded with its second bill only by keeping out of sight of all mansions, and avoiding the game-preserves,—since the time when the London and Birmingham Company, after seeing their project thrown out by a committee of peers who ignored the evidence, had to conciliate their antagonists by raising the estimate for land from L.250,000 to L.750,000,—since the time when parliamentary counsel bolstered up a groundless resistance by the flimsiest and absurdest excuses, even reproaching engineers with having trodden down the corn of widows, and destroyed the strawberry-beds of gardeners;—since then a marked change of policy has taken place. Nor was it in human nature that it should be otherwise. When it became known that railway companies commonly paid for land and compensation sums varying from L.4000 to L.8000 per mile,—that men were indemnified for supposed injury to their property by sums so inordinate that the greater part has been known to be returned by the heir as conscience-money,—that in one case L.120,000 was given for land said to be worth but L.5000,—when it was bruited abroad that large bonuses in the shape of preference shares and the like were granted to buy off opposition,—when it came to be an established fact that estates are greatly enhanced in value by the proximity of railways, it is not surprising that country gentlemen should have become active supporters of schemes to which they were once the bitterest enemies." The Eastern Counties Railway Company had, up to 1846, paid not less than L.809,950 for land and compensation, equal to about L.12,000 per mile. The cost of the land purchased by the original London and Birmingham and Great Western railway companies averaged not less than L.6300 per mile.

But the most conspicuous example, in recent times, which overshadows all others, of excessive expenditure in parliamentary litigation, as well as in land and compensation, is supplied in the history of the Great Northern Railway Company. The preliminary expenses of surveys, notices to landowners, &c., commenced in 1854, and the bill was introduced into the House of Commons in 1855, when it was opposed by the London and North-Western, the Eastern Counties, and the Midland railways. It was further opposed successively by two other schemes called the London and York and the Direct Northern. The contest lasted eighty-two days before the House of Commons, more than half the time having been consumed by opposition to the bill. The bill was allowed to stand over till next year (1846), when it began before the committee of the House of Lords where it left off in the Lower House in the year 1845, on account of the magnitude of the case. The bill was before the Upper House between three and four weeks; and in the same year (1846) it was granted. The promoters of the rival projects were bought off, and all their expenses paid, including the costs of the opposition of the neighbouring lines already named, before the Great Northern bill was passed; and the "preliminary expenses," comprising the whole expenditure of every kind up to the passing of the bill, was L.590,355, or more than half a million sterling, incurred at the end of two years of litigation. Since the passing of the act an additional sum of L.172,722 has been expended for "law and engineering expenses in Parliament" to 31st December 1857, which has been spent almost wholly in obtaining leave from Parliament to make various alterations. Thus it would appear that a sum total of L.763,077 was spent as parliamentary charges for obtaining leave to construct 245 miles, being at a rate of L.3115 per mile.

During the same period, the payments made by the Great Northern Railway Company for "land and compensation" amounted to L.1,901,371, or nearly two millions sterling, at the rate of L.7760 per mile. The parliamentary and land and compensation charges together make a sum of L.2,664,448, or L.10,875 per mile of the original line. The total payments on capital account were L.11,299,300; and of this amount, those items constitute the formidable proportion of 23½ per cent., being nearly one-fourth of the capital forestalled before the ground was broken.

The particulars of the Peebles Railway may next be quoted in contrast to those of other lines, as a perfect example of economical construction and legitimate expenditure. The railway is a single line, 18¾ miles in length, from Peebles station to the point of junction with the North British Railway at Eskbank station, 8 miles from Edinburgh. There was no opposition to the project in any quarter, and the landowners agreed to give the lands required at thirty-five years' purchase of the agricultural value,—the value and severance damage being fixed by arbitration. Nor did the turnpike-road trustees make any claim for damages. The act was passed in July 1853, and the actual cost of obtaining it was only L.650, no fees to counsel having been found necessary. The total parliamentary expenses, up to the obtaining of the act, was L.1569; but further expenses were incurred in 1857 in applying for power to raise new capital. The charges for land and compensation amounted to L.21,222, or L.1131 per mile. Seven stations, with approaches, including Peebles station, averaging one for every 2¾ miles, were built at an average cost of about L.1200 each. The works were constructed for about L.3600 per mile, and the locomotive and carrying stock cost about L.1000 per mile. The railway was opened in July 1855, two years after the passing of the act. The total cost at the end of 1858 amounted to L.6688 per mile, of which the following is an analysis:—

	Total.	Per Mile.
Preliminary and parliamentary expenses	L.2,753	L.147
Engineering and surveying	2,400	128
Land and compensation	21,222	1131
Works	67,157	3582
Stations, sheds, &c.	8,352	445
Interest	543	29
General charges	1,424	76
Electric telegraph	710	38
Machinery	259	14
Locomotive and carrying stock	20,590	1098
Total capital cost in 1858	L.125,410	L.6688

Reform in Railway Legislation.—In 1858 a select committee of the House of Commons was appointed to consider the best means of amending the tribunal for the examination of railway bills. One object was to diminish the time and labour of the members of committees on railway bills; the other was to diminish the cost of the pro-

Railway Legislation

ceedings. From the evidence taken it appeared generally that there was a want of consistency and uniformity of principle in the modes of dealing with railway bills by committees of the House, and also a needless expenditure of time and money, in consequence of the changing elements of committees, and their want of experience; that the permanent appointment of paid chairmen of character and experience would considerably expedite the business of committees, and diminish expenses, principally from their being able to direct the inquiry, to conduct deliberations, to prevent irrelevancy, to restrain superfluous evidence, and to keep counsel in check. It was also suggested, that all parties should be allowed to appear in opposition before committees, and that the check upon the abuse of that privilege should be the power of examining witnesses on oath, as is done before committees of the Upper House, and of awarding costs in cases of vexatious or unnecessary proceedings. It appeared in evidence that during the eleven years 1847-57 the number of railway bills introduced was 913, or 83 per annum, on which the committees sat 1676 days, or 152 days per annum. The committee reported in favour of a few obvious expedients suggested by the evidence, but did not deal with the essential elements of reform,—namely, the recognition of a permanent tribunal or, at all events, of permanent chairmen or judges, and the power of awarding costs.

Mr Stephenson, in 1856, suggested that, instead of leaving the treatment of railway bills to inexperienced tribunals,—the ordinary parliamentary committees,—a mixed commission should be organized of practical men of acknowledged legal, commercial, and mechanical ability, willing to devote its attention to railway subjects only. "Give us," he said "a tribunal competent to form a sound opinion. Commit to that tribunal, with any restrictions you think necessary, the whole of the great questions appertaining to our system. Let it protect private interests, apart from railways; let it judge of the desirability of all initiatory measures, of all proposals for purchases, amalgamations, or other railway arrangements; delegate to it the power of enforcing such regulations and restrictions as may be thought needful to secure the rights of private persons, or of the public; devolve on it the duty of consolidating, if possible, the railway laws, and of making such amendments thereon as the public interests and the property now depending upon the system may require; give it full delegated authority over us in any way you please; all we ask is, that it shall be a tribunal that is impartial, and that is thoroughly informed; and if impartiality and intelligence are secured, we do not fear the results." Mr Stephenson, apprehends, nevertheless, that any such tribunal appointed by government would fail to give adequate security for the proper fulfilment of the high duties which they would have to perform. Probably such an intermediate course as that suggested in the evidence, already alluded to, before the committee on railway legislation, would be advisable, as a preliminary step to a more perfect institution. No one will doubt, after the experience of the last 30 years, that it would have been better for the railways had they never appeared against each other at all; for it is clear that the money which has been spent unproductively, in opposition before committees, would have been economized. It is obvious that the reduction of dividends to less than one-half of their former amount by a course of fruitless litigation and profitless accumulation of capital, which has nothing to show for it, had better have been effected by doubling the extent of railway communication and subdividing the traffic, even supposing such a declension of dividend to follow of necessity the extension of railways. The fact is, however, that the dividends would have continued undiminished under liberal management, even with all the additional new lines, because the business of the old-established lines really has not declined, but, on the contrary, has wonderfully and unexpectedly augmented.

Railway Management.

MANAGEMENT OF RAILWAYS.

Railways, as a system, have been upwards of twenty years in operation, and have been wrought with various degrees of success. In all that appeals directly to common-sense, common feeling, discretion, judgment, and reputation, railways have upon the whole been successfully and creditably managed. They have, however, been afflicted with the worst evils characteristic of joint-stock management, of which the central vice and weakness may be expressed in a few words,—namely, that the interests of the managing class are different and distinct from those of the proprietary body. Mr Stephenson, sensible of the defects of the prevailing system of management, promulgated in 1856 a plan of working railways on lease, which appears to provide for the real necessities of the situation. "Looking at the question in a broad point of view," he says, "the consideration occurs, whether it might not be possible, by some operation analogous to that of a trading company under the Limited Liability Act, to give an entirely new and greatly improved character to the relations between shareholders and managers? Suppose a limited number of men of business, varying say from ten to twenty, and capable of giving good security, agreed together to take a line from the shareholders at a fixed rental. They might depute their management to two or three of their own body; or even, if the line was short, to one *gérant*. Under such circumstances there would be no clamour from shareholders at half-yearly meetings—no sudden changes of directorates, involving ruinous alterations of policy,—no cabals between one set of directors and another,—and no mischievous interferences with the development of the system. The manager, free from the apprehension of being saddled personally with all the responsibility and liability, would be able to embark in enterprises not comprehended in the terms of the act of Parliament, but essential to the prosperity of their line." "They would be free from apprehensions as to the liabilities they incurred; and whilst they would not be turned from their course of policy by the outcry of any discontented individual able to make his voice heard through any public channel, they would give practical security that the public interests would be consulted, because the interests of the public and those of the managers would be in every respect identical." These important observations point precisely to the general principle essential to permanent success; and it may be added that they are confirmed by the great authority of Mr Bidder, who has frequently directed his large capacity and pure analytical mind to the most complicated and most delicate questions of railway policy. (D. K. C.)

(The following authorities have been consulted in the preparation of this article:—*Report of the Railway Department of the Board of Trade*, 1857; *Report of the Select Committee of Parliament on Railway and Canal Legislation*, 1858; *Report of the Select Committee of Parliament on Accidents on Railways*, 1858; *Minutes of Proceedings of the Institution of Civil Engineers*, 1850–1858: "Permanent Way," "Railway Stations," "Railway Accidents," Address of Mr Stephenson as president, Address of Mr Locke as president; *Minutes of Proceedings of the Institution of Mechanical Engineers*, 1851–58: "Railway Carrying Stock," "Locomotive Workshops;" *Railway Machinery*, by D. K. Clark, 1855; *Statistics of Metropolitan Railways*, by D. K. Clark, 1853; *European Railways*, by Holley and Colburn, 1857; *On Deterioration of Railway Plant and Road*, by Mark Huish, 1849; *Railways, their Capital and Dividends*, by E. D. Chattaway, 1856.)

RAIMBACH, ABRAHAM, a distinguished line-engraver, was a Swiss by descent, and was born in London in 1776. His eminence in art was attained by assiduous industry. Becoming an apprentice to Hall the engraver in 1789, he continued in that capacity till 1796, engraving under his master's eye all day, and training his hand in sketching at night. He then had recourse to various means of improvement. Part of his working-time was devoted to the study of drawing in the Royal Academy; another part was occupied in executing occasional engravings for the booksellers; his leisure hours were employed in eking out his scanty income by painting portraits in miniature. It was not until he had laboured in this manner for about nine years, that he received a sufficient number of commissions in engraving to engage all his efforts. Raimbach had not been long established in his profession when he formed an intimacy with Sir David Wilkie, and the result was, that in 1812 he began to engrave some of that master's best pictures. With such great originals as models, his prints attained the highest excellence. "The Village Politicians," "The Rent-Day," "The Cut Finger," "Blind-Man's Buff," "The Errand-Boy," "Distraining for Rent," "The Parish Beadle," and "The Spanish Mother and Child," although at first they did not sell so well as was expected, raised him in the estimation of connoisseurs. The French especially held him in great honour. At the time of his death, in 1843, he held a gold medal which had been awarded to him for his "Village Politicians," at the Paris Exhibition of 1814, and the title of Corresponding Member of the Institute of France, which had been bestowed upon him in 1835. The autobiography of Raimbach was edited by his son, for private circulation, under the title of *Memoirs and Recollections of the late Abraham Raimbach, including a Memoir of Sir D. Wilkie, R.A.*

RAINBOW. See METEOROLOGY, and OPTICS.

RAISINS are the dried fruit of the grape-vine (*Vitis vinifera*, Linn.; Nat. Ord. *Vitaceæ*, Lind.; the *Ampelideæ* of Decandolle). The grape, which is the most extensively useful of all known fruits, is, according to its varieties, and the methods used in preparing them, converted into various kinds of raisins, some of which form very important articles of commerce. The finest are those which are dried on the vine, and retain the beautiful bloom which covers the ripe grape. They are called *Muscatel* raisins, and are imported to this country chiefly from Malaga, whence they come in boxes, in which the bunches are entire, and are carefully packed in layers, with white paper between them. To prepare Muscatel raisins, the grapes, when ripe, are allowed to remain on the vines, but the main stalk of each bunch is partially severed, enough only being left uncut to prevent the weight of the cluster from breaking. The leaves which shade the grapes are cut off, and the bunches fully exposed to the sun, which makes them shrivel, and loose much of their original watery fluid. The pulp remaining becomes by concentration very sweet. Thus prepared, they are often called "raisins of the sun," but are generally termed Malaga or Muscatel raisins.

The more common sorts of raisins are gathered when ripe, and are either laid in the sun, or are dried in heated rooms; they are sprinkled whilst drying with an alkaline lye, which is generally made by burning the prunings of the vines, and filtering water through the ashes. The water dissolves the potash in the ashes, and becomes strongly alkaline. This part of the process causes the saccharine matter of the grape, which is a peculiar variety of sugar imperfectly crystallizable, to form rounded concretions, and also partially to exude and cover the skin of the raisin with a thin saccharine varnish. A lye made of water, ashes, and oil, is sometimes used, and the raisins prepared with it are in consequence named *Lexias*. The *black Smyrna* raisins are small, dry, and black, without the white concretions of grape-sugar, which are so abundant in the Sultana, Valentia, and Denia raisins, or Lexias, as the two latter varieties are sometimes called. The best kinds of Lexia, or lye-prepared raisins, are gathered with the bunches entire, and are hung on lines in the sun; when they begin to shrivel they are dipped in the lye once or twice, and again hung up to complete the curing; they are then carefully packed in boxes (containing about 56 lb.), half-boxes, and quarter-boxes. The fine Turkish raisins, called *Sultanas*, are always packed in cylindrical boxes, technically called *drums*. The grape from which this most delicious of all raisins is prepared is remarkable for being seedless and small; whereas the only other Turkish raisin known in commerce, the black Smyrna, has very large seeds, although it is a small fruit.

Another instance of a seedless variety of the grape is found in the common *currant* of the grocers, the Corinth or Corinthian grape of old writers. This is the smallest of all the varieties of the grape; it is only cultivated in the Greek islands, where it forms a most important crop. It is most extensively grown in Patras, Zante, Ithaca, and Cephalonia, comparatively few coming from Corinth, whence its commercial name was derived. The clusters of the Corinth grape are remarkably small, generally about 3 inches in length, the grapes being only the size of peas; they are gathered from the vines when ripe, and are laid up in heaps, called *couches*, exposed to the sun. When dry, they are cleaned from the stalks and deposited in rooms called *seraglios*, where, owing to the exudation of grape-sugar on their surface, the berries become sticky, and they adhere firmly together, so as to require digging out. When required for use, they are trodden into large casks called *butts*, averaging about 18 cwt.; *caroteels* or *tierces*, averaging about 7 cwt.; and *barrels*, of from 2 to 3 cwt. each. They are also now very frequently packed in boxes of from 1 to 1½ cwt. Although these different kinds of dried grapes are only used in cooking and confectionary, the trade done in them is enormous, and, as far as this country is alone concerned, employs a very large amount of shipping. The imports in 1858 were:—

	Cwt.
Of Raisins,—	
From Spain	243,147
,, Italy and Sicily	4,701
,, Turkey	57,309
,, Other countries (into which they have been imported)	5,263
Of Currants,—	
From Greece	308,763
,, Ionian Islands	63,270
,, Other countries (into which they have been imported)	32,820

Wine is often made from raisins, and that of Malaga is chiefly manufactured from the dried grape. The luscious Hungarian wine, Tokay, is made from grapes partially converted into raisins on the vine. Raisin wine was made by the ancient Romans, and other nations of antiquity. The raisin wines of Crete, Cilicia, and Africa, were highly prized by the epicures of Rome. (T. C. A.)

RAJAH, a hereditary prince among the Hindus belonging to the warrior caste, or the Cshatriya. (See CASTE.)

RAJAHMUNDRY, a district of British India, in the presidency of Madras, lying between N. Lat. 16. 18. and 17. 38., E. Long. 81. 7. and 82. 40., bounded on the N. by Orisa, N.E. by the district of Vizagapatam, S.E. and S. by the Bay of Bengal, W. by the district of Masulipatam, and N.W. by the Nizam's territories; area, 4501 square miles. The northern and north-western portions of the district are occupied with hills, which resemble in character the eastern ghats farther to the west, and are of a granitic structure, mixed with gneiss, trap, and calcareous tufa. The centre of the country contains some lower hills of alluvial formation, and the ground along the coast is low and flat. The only large river is the Godavery, which enters the district from the north, and flows through it in a southerly direction for 49 miles. It then divides into two branches, that to the right flowing S. and S.W. for 45 miles, and the other S.E. and E. for 52 miles. In the delta thus formed lie some of the richest and most fertile tracts in the whole of India. The soil of the level ground is generally alluvial and fertile, especially along the banks of the river, where there is a rich dark mould suitable for the growth of cotton. Besides this plant, tobacco, indigo, sugar, rice, maize, millet, pulse, and other crops, are raised in the district. The Godavery is navigable for boats, and much teak wood is floated down by it. The water is used for the purposes of irrigation. In the bed of the river are many small islands of rich soil, some formed naturally by the deposit of silt, and others by artificial means. The climate is warm, and generally healthy, except in the valleys and jungles towards the north-west, where a deadly malaria prevails. Rajahmundry, the principal town of the district, stands on a rising ground on the left bank of the Godavery, 285 miles N.E. of Madras, and 580 S.W. of Calcutta. It has one main street, lined with low mud houses roofed with tiles. This street contains the chief bazaar, and runs along the river's bank; and several smaller streets branch off from it on either side. To the north of the town stands a square fort surrounded with mud walls, and containing barracks, hospital, jail, and magazine. There are many mosques in the town, but the Mohammedans are few and poor. Pop. of the town, 15,000 or 20,000; of the district, 1,012,036.

RAJESHAYE, a district of British India, in the presidency of Bengal, bounded on the N. by the district of Dinajepore, N.E. by that of Bogra, E. and S.E. by that of Pubna, S. by that of Nuddea, W. and N.W. by those of Moorshedabad and Malda; length, from E. to W., about 62 miles; breadth, 50; area, 2084 square miles. It is a very moist region, being traversed by numerous rivers from the Himalayas in the north. The largest of these is the Ganges, which washes the S.W. border of the district. There are also many swampy lakes, some of them of large size; and in the periodical inundations to which the country is subject, many channels, generally dry, are filled with water. Rice is the chief crop raised here, but corn and pulse of various kinds are also grown. Indigo and silk are the most important commercial products of the country. Pop. 671,000.

RAJMAHAL, a town of British India, in the district of Bhangulpore, presidency of Bengal, and 196 miles N.W. of Calcutta, on a steep bank on the right side of the Ganges, which sweeps past with a broad, impetuous current, sometimes washing away large portions of the land. It contains the ruins of two palaces and two mosques, one of which is a large imposing building, though of rude execution. The houses are generally mean and ruinous, clustered round twelve separate market-places; and the appearance of the town is wretched. Rajmahal is a place of very great antiquity; according to one account, having been founded more than 3000 years B.C. It was ceded to the British in 1765. Pop. estimated at 30,000.

RAJPEEPLA, a petty state of India, in the province of Guzerat, presidency of Bombay, lying between N. Lat. 21. 23. and 21. 59., E. Long. 73. 5. and 74; area, 1650 square miles. It is partly mountainous, and occupied by wild tribes of Rajpoots and Bheels; but the peasants of the plains are an industrious, peaceful class, devoted to agricultural pursuits. The most important products of the country are cornelians, which are obtained from mines, and conveyed to Cambay, where they are cut and polished. The profits derived from this source have recently fallen off to a considerable extent. The chief river in Rajpeepla is the Kurgun, on which Nandode, the capital, stands. The state was at first independent; then for a time it became tributary to the sovereigns of Delhi; and finally to the Guicowar state, to which it still pays tribute. The British government has, however, a certain authority over Rajpeepla. Pop. 122,100.

RAJPOOTANA, an extensive region of India, lying between N. Lat. 23. 35. and 29. 57., E. Long. 70. 5. and 77. 40.; bounded on the N. by the British district of Butteeana; N.E. and E. by those of Kurreeana and Goorgaon, and by the states of Jhujhur, Bhurtpore, Dholpore, and Gwalior; S. by the territories of Scindia, Holkar, and the Guicowar, by Jabbooa and Myhee Caunta; and W. by Scinde and Bhawulpore. Length, from E. to W., 420 miles; breadth, about 400. It is divided into the following distinct states:—

	Area in Sq. miles.	Population.
Beekaneer	17,676	539,250
Shekawuttee	3,895	...
Alwur	3,573	280,000
Jessulmere	12,252	74,400
Joudpore	35,672	1,783,600
Jeypore	15,251	1,891,124
Serohee	3,024	...
Mairwarra (British)	282	37,715
Ajmere (British)	2,029	224,891
Kishengurh	724	70,000
Tonk	1,864	18,672
Oodeypore	11,614	1,161,400
Bhoondee	2,291	229,100
Kotah	4,339	433,900
Jhallawar	2,200	...
Doongerpore	1,000	100,000
Banswarra	1,440	144,000
Pertabgurh	1,457	145,700
Kerowlee	1,878	187,800
Total	122,461	

The country derives its name from the Rajpoots, a peculiar race of men who inhabit it. They are believed to be descended from the *Kshestriyas*, or warriors, one of the four original castes of the Hindus. It is not known at what period they first appeared as a distinct nation, but they attained a high degree of power and renown just before the Mohammedan conquests in the twelfth century. At that time they possessed an extensive dominion, including Delhi, Kunnouj, and Guzerat. In 1193 and 1194 the Rajpoot chiefs sustained more than one defeat at the hands of the Mohammedans, and were deprived of all their possessions except the regions they now occupy. In many other parts of India, however, scattered members of the Rajpoot race are to be met with. The character of this people is remarkable, and exhibits many traces of their military origin. A sort of feudal system is the polity of the nation; the various clans into which the people are divided form societies of men, closely connected one to another, and devoted to their chieftains; and these chieftains, again, are similarly related to each other and to the rajah. Many of the peculiar features of the mediæval chivalry are or were discernible among the Rajpoots, though perhaps after a ruder and less elevated pattern. Among these are the deference paid to women, the code of honour towards their enemies, the pride of birth, and the delight in warlike exploits which mark this warrior tribe of Hindus. These good qualities are not unmixed with the greatest vices. Suttee and infanticide are the most atrocious of these; treachery and cruelty are by no means unknown among them; and even their courage, so far from being a cool and steady determination, is avowedly stimulated by the intoxication of opium. Improvements are now being introduced gradually into the country, under the protection of the British, which is proving very beneficial. It is exercised through an agent for the states of Rajpootana. This connection with the British originated about the beginning of this century, when the Rajpoots proved unable to defend their country against the Mahrattas.

RAKE OF A SHIP is that part of the hull which hangs over both ends of the keel. That which is before is called the *fore-rake* or *rake forward*, and that which is behind is called the *rake-aft* or *afterward*.

RAKKA, a town of Asiatic Turkey, capital of a pashalic of the same name, on the left bank of the Euphrates, 92 miles S.E. of Birr. It contains the ruins of a palace of the Caliph Haroun-al-Raschid. The ancient *Nicephorium*, a town founded by the Macedonians, occupied this site; a fortress was erected by Justinian; and new defences were added by the Emperor Leo, from whom it got the name of *Leontopolis*. Pop. 8000.

RALEIGH, SIR WALTER, fourth son of Mr Walter Raleigh of Fardel, in the parish of Cornwood in Devonshire, was born in 1552 at Hayes, in the parish of East Badley, a farm belonging to his father. About the year 1568 he was sent to Oriel College, Oxford, where he continued but a short time. He became one of the hundred volunteers, commanded by Henry Champernon, who, with other English troops, were sent by Queen Elizabeth to assist the Queen of Navarre in defending the Protestants. He has described some of the great battles in which he was engaged in his *History of the World*. In 1577 or 1578 he proceeded to the Low Countries with the troops sent by the queen to assist the Dutch against the Spaniards, and probably shared the glory of the decisive victory obtained over Don John of Austria in 1578. On his return to England, a new enterprise engaged his attention. His half-brother, Sir Humphrey Gilbert, having obtained a patent to plant and inhabit some parts of North America, Raleigh embarked in this adventure; but meeting with a Spanish fleet, after a smart engagement, they returned without success in 1579.

The following year the King of Spain, in conjunction with the Pope, having projected a total conquest of the English dominions, sent troops to Ireland to assist the Desmonds in the Munster rebellion. Raleigh obtained a captain's commission under Lord Grey of Wilton, then deputy of Ireland, and embarked for that kingdom, where he greatly distinguished himself both for bravery and for skill. He returned to England, and attracted the notice of Queen Elizabeth, owing, as we are told in Naunton's *Fragmenta Regalia*, to the following accidental piece of gallantry:—The queen, as she was one day taking a walk, being stopped by a soft place in the road, Raleigh immediately took off his new plush mantle, and spread it on the ground. Her majesty trod gently over the soft foot-cloth. Surprised and pleased with the adventure, and much struck by the noble appearance of the young soldier, she admitted him to her court, and employed him first as an attendant on the French ambassador Simier, upon his return home, and afterwards to escort the Duke of Anjou to Antwerp. During this excursion he became personally known to the Prince of Orange, from whom, at his return, he brought especial acknowledgments to the queen, who now frequently conversed with him. But the inactive life of a courtier did not suit the enterprising spirit of Raleigh. He took advantage of his favour with the queen to obtain in 1584 a patent empowering him to possess such countries as he should discover on the continent of North America. Accordingly he fitted out at his own expense two ships, which sailed in the month of April, and returned to England about the middle of September, reporting that they had discovered and taken possession of a fine country, to which the queen gave the name of *Virginia*. About this time he was elected knight of the shire for the county of Devon, and soon afterwards received the honour of knighthood. To enable him to carry on his designs abroad, the queen granted him a patent for licensing the venders of wine throughout the kingdom. In 1585 he sent a new expedition to Virginia, commanded by his relation Sir Richard Greenville, who left a colony at Roanoak of 107 persons, under the government of Lane; and by the establishment of this colony he was enabled to import tobacco into England. In the same year Sir Walter Raleigh obtained a grant of 12,000 acres of the forfeited lands in the county of Cork in Ireland, which, instead of yielding him any profit, cost the proprietor L.200 a year to keep them from invasion and havoc. This consideration induced Raleigh to sell his lands to Boyle, afterwards Earl of Cork. About the same time he was made seneschal of the duchy of Cornwall, and warden of the stanneries.

In the year 1587 he sent another colony to Virginia; but his various undertakings and offices obliged him to assign his patent to a company, and the plan of colonizing was by them speedily relinquished; so that the unfortunate colonists were left to their fate. About this time we find Raleigh distinguished by the titles of "Captain of the Queen's Guards," and "Lieutenant-General of Cornwall." From this period to the year 1594 he was continually engaged in projecting new expeditions, defending the kingdom from the insults of the Spaniards, and transacting parliamentary business, with equal ability and resolution. Sir Walter fell under the queen's displeasure on account of an alleged intrigue with the daughter of Sir Nicholas Throgmorton, one of the maids of honour; however, he married the lady, and lived with her in great conjugal harmony. During his disgrace at court he projected the conquest of Guiana in South America, and in 1595 sailed for that country, in the vain hope of discovering the golden region of El Dorado, supposed to be situated in the depths of Guiana. He returned to England the same year, and soon afterwards published an account of his expedition. In the following year he was one of the admirals in the successful expedition against Cadiz, gained mainly by his skill and valour, under the command of Howard and the Earl of Essex; and in 1597 he sailed with the same commanders against the Azores. Soon after these expeditions we find him assiduously engaged in parliamentary business. His speeches evince a knowledge of political economy far superior to any man of his time. He had so far regained the royal favour as to obtain a grant of the manor of Sherborne in Dorsetshire, which he magnificently embellished. Fuller mentions a tradition that the first orange-trees that ever grew in England were planted by his hand. This tradition is rendered the more likely by his recorded fondness for horticulture. In truth his genius was as varied and discursive as it was powerful. He could turn himself with surprising facility from mathematics to poetry, from the profoundest cosmographical speculations or metaphysical disquisitions to the lighter subjects of music, from ornamental gardening or painting to historical or antiquarian researches; and all the while kept up his intercourse with the world and the court, and was ready to avail himself of any new avenue which might open up to his ambition or his love of glory. In 1600 he was sent on a joint embassy with Lord Cobham to Flanders, and on his return made governor of Jersey.

Queen Elizabeth died in the beginning of the year 1603; and with her Raleigh's glory and felicity sunk, never to rise again. Upon the accession of James, Sir Walter lost his interest at court, was stripped of his preferments, and foully accused of a plot against the king. He was arraigned at Winchester, and, on his trial, was insulted with the most shocking brutality by the famous Coke, attorney-general, who influenced the jury to convict him without any legal proof of his guilt. After a month's imprisonment, however, in daily expectation of his execution, he was reprieved and sent to the Tower, and his estates were given to Car, Earl of Somerset, the king's favourite. During this confinement he wrote many of his most valuable pieces, particularly his *History of the World*. In March 1615, after sixteen years' imprisonment, he obtained his liberty, and immediately began to prepare for another voyage to Guiana, which proved equally abortive and ruinous. His eldest son, who bore his father's name, and a lad of infinite spirit, was slain by the Spaniards, and Captain Keymis, the head of the expedition, committed suicide. In the year 1618 he returned to England, where he was soon afterwards seized, imprisoned, and beheaded. He was sacrificed by the pusillanimous monarch to appease the Spaniards, who, whilst Raleigh lived, thought every part of their dominions in danger. He was executed in Old Palace Yard, and buried in St Margaret's adjoining, in the sixty-sixth year of his age. His behaviour on the scaffold was manly, unaffected, cheerful, and easy. Being asked by the executioner which way he would lay his head, he answered, "So the heart be right, it is no matter which way the head lies." He was a man of admirable parts, extensive knowledge, undaunted resolution, and perhaps the best prose writer of his age. He was upwards of six feet in height; and in his demeanour, says Aubrey, "he presented an awfulness above other mortals." His great work, the *History of the World*, is a truly remarkable performance, both for matter and style. It has often been reprinted. His Life has frequently been written, and once exceedingly well by Patrick Fraser Tytler for the "Edinburgh Cabinet Library," 1833. An edition of his whole works was published at Oxford in 1829, in 8 vols. 8vo.

RAMADAN. See Bairam.

RAMBERVILLERS, a town of France, in the department of Vosges, on the right bank of the Mortagne, here crossed by a stone bridge leading to a suburb on the opposite side, 16 miles N.E. of Epinal. It is in general well built, but contains no conspicuous public edifices. There are a public library of 10,000 volumes, forges, tanneries, manufactories of woollen cloth, linen, pottery, &c.; and some trade in corn, hemp, hops, cutlery, and other articles. Pop. 4841.

RAMBLA, a town of Spain, Andalucia province, and 17 miles south of Cordova. It has straight and well-paved streets, good houses, and several squares; but few of the public buildings are particularly deserving of notice. There are several convents and churches, and the people are mostly employed in farming, but also in the manufacture of earthenware, linen, and woollen fabrics, &c. Pop. 9040.

RAMBOUILLET, a town of France, in the department of Seine-et-Oise, 17 miles S.W. of Versailles. The dull place is remarkable for nothing but the ugly, gloomy, red brick castle, with five flanking stone towers, surrounded by a large park and forest. In the great tower is the room where Francis I. died in 1547. Here, too, another monarch took his leave of the French throne,—Charles X., under the terror of the fate of Louis XVI., signed his abdication August 2, 1830. Since then the building has not again been the residence of royalty; but the present emperor made it, in 1852, a seminary for officers' daughters. Pop. (1856) 4363.

RAMESES. See Egypt.

RAMGURH, a district of British India, presidency of Bengal, bounded on the N. by the district of Behar, N.E. by that of Mongheer, E. by that of Beerbhoom, S. by that of Chota Nagpore, and W. by that of Palamow; lying between N. Lat. 23. 20. and 24. 50., E. Long. 83. 30. and 81. 38: length, from E. to W., 675 miles; breadth, 90; area, 8524 square miles. Much of the surface is gently undulating, with groups of hills here and there, and in some places extensive table-lands. Granite, quartz, and other primitive rocks are the components of some of the hills; and the country is rich in ores of coal, iron, lead, antimony, and probably also silver. Numerous rivers, but none of large size, water the country. They flow generally to the S.E., discharging their waters into the estuary of the Ganges; but some take a northern course, and join that river at a higher point. Vast, dense, and impenetrable are the forests with which a great part of the district is covered, haunted by many kinds of wild beasts and poisonous serpents, the dread of the inhabitants, who are thinly scattered over the country, dwelling in mud villages, and engaged chiefly in tilling the soil. Nothing that deserves the name of a town is to be seen. Pop. 372,216.

RAMMOHUN ROY, Rajah, a Hindu of wonderful talents and enlightenment, was born at Burdwan in the province of Bengal, about 1774. His parents, descended from Brahmins who had held high offices, both secular and sacred, resolved to make their boy worthy of his distinguished ancestry. The greatest care was taken in fitting his mind for his high prospects. The Persian and Arabic tongues were taught him, that he might attach himself to the court of Mohammedan princes. Sanscrit also was added to his education, that he might be competent to hold a sacerdotal office among the Hindus. Yet the young lad had not reached his sixteenth year before circumstances occurred to turn his thoughts in a direction different from that which had been marked out for him. His intercourse with the Moslems made him acquainted with the doctrine of the unity of the Godhead. The dogma recommended itself to his understanding, and shook his faith in the idolatrous system of worship which his fellow-Brahmins were observing. This feeling of doubt drove him to the ancient Hindu scriptures for further enlightenment. Finding that they distinctly taught the existence of one Supreme Being, he became from that time an advocate of monotheism. Boy though he was, he lost no time in composing a manuscript to show how the Hindus had corrupted the primitive simplicity of their faith. Frowns and rebukes from the entire circle of his acquaintance immediately assailed him; but they were only the means of making him pursue the investigations which he had already begun. Driven from home by the coolness of his father, and induced to sojourn for a time in Thibet, he studied all the forms of religion that came under his view. Then, after a lapse of two or three years, he returned to his paternal abode, confirmed in his aversion towards idolatry, and bent upon seeking additional enlightenment both in the oracles of his own caste and in other religious creeds.

About 1814 Rammohun Roy, living in a house in the Circular Road, Calcutta, began to be known as the most extraordinary man among the Brahmins. There were many qualifications which combined to give him this position. His patrimony was handsome. His bearing was pleasing, courtly, and imposing. His moral character was pure, earnest, and philanthropic. Still more striking were the intellectual attainments which he possessed. A more richly endowed, active, and far-searching mind could scarcely be found. The weapons of logic were thoroughly at his command. He could also range through the provinces of Sanscrit, Persian, and Arabic literature. Especially was he at home in English politics and letters. In fact, wherever in the entire region of learning truth seemed to point the way, thither did he strive with a European daring and invincibility.

This energetic and gifted native could not long remain inactive, and Rammohun Roy soon appeared in the character of a reformer of Brahminism. The plan he employed was, to seek out and lay before the Hindus those simple precepts of religion and morality which he might find within the range of his reading. He began his endeavours by translating into Bengali, Hindustani, and English the *Vedant*, "the most celebrated and revered work of Brahminical theology." He then published in English and Bengali some of the principal chapters of the *Veda*, the body of Hindu divinity. His next attempt was to draw up a compendium of the morality of the Christian religion. Greek and Hebrew were accordingly acquired, that he might examine and prove the Scriptures in the original. The result was a book, produced in 1820, in English, Sanscrit, and Bengali, and entitled *The Precepts of Jesus the Guide to Peace and Happiness.* More selections would also have been prepared by him had he not been engaged for three years in defending his last publication against the animadversions of Dr Marshman and other Christian writers.

Rammohun Roy's labours for the enlightenment of his countrymen ended with 1830. A visit to England had long been one of the cherished enterprises of his mind. Taking advantage of his appointment as ambassador from the King of Delhi to the British government, he now set sail, and arrived at Liverpool in 1831. He was just beginning to form a large circle of friends throughout the country when he died at Stapleton Grove, near Bristol, on the 27th of September 1833. (See *A Review of the Labours, Opinions, and Character of Rammohun Roy*, by Lant Carpenter, LL.D., London, 1833.)

RAMNAD, a town of British India, presidency of Madras, in the district of Madura, capital of a zemindary of the same name, stands near the coast of Palk's Bay, 60 miles S.E. of Madura. It is inclosed by a wall and ditch about 2½ miles in circuit; but the former is now in a ruinous condition, and the latter nearly filled up. Viewed from the flat country around, the town presents a conspicuous appearance, with its massive triangular fort, its ancient and richly-adorned palace, and its pagodas rising to the sky. The streets are narrow and ill kept, but the houses are pretty good. A Protestant church, Roman Catholic church, several inconspicuous but elegant mosques, and two bazaars, are among the other buildings. The only manufacture is that of coarse cloth. Pop. 13,000, of whom about 6000 live in the fort.

RAMPANT. See HERALDRY.

RAMPART. See FORTIFICATION.

RAMPOOR, a jaghire or fief of British India, in the division of Rohilcund, bounded on the N. by the district of Pilleebheet, E. and S. by that of Bareilly, and W. by that of Meradabad, lying between N. Lat. 28. 30. and 29. 11., E. Long. 78. 55. and 79. 30. A level, fertile country, watered by the Kosila and Nahul, flowing southwards, it is partially occupied in the north by marshy forests and jungle, where the climate is exceedingly unhealthy; but in the south it presents a wide expanse of waving corn-fields, broken only by small villages or groups of mangoes and bamboos. It is occupied by an industrious and intelligent people, who are chiefly employed in farming. The capital is a large and populous town of the same name, on the left bank of the Kosila, 789 miles N.W. of Calcutta. It is built chiefly of mud, but contains a lofty mosque. Pop. estimated at more than 320,000.

RAMSAY, ALLAN, a Scottish poet, was born at Leadhills in Lanarkshire on the 15th October 1686. His father was employed in the management of Lord Hopetoun's mines at that place, but died whilst the poet was yet in his infancy. He remained at the parish school of Leadhills with tolerable regularity till he reached his fifteenth year, and was employed in washing, preparing the lead ore for smelting, and other operations about the works. In 1701, when in his fifteenth year, he was bound apprentice to a wigmaker in Edinburgh, an occupation at which he continued till 1716. One of the earliest of Ramsay's productions now known, an address to the members of the Easy Club, appeared in 1712, when he was twenty-six years of age; and three years afterwards he was humorously appointed their poet-laureate. Many of his poems written about this time were published in the form of separate pamphlets. After having followed the occupation of wigmaker for a considerable time, he finally abandoned it for that of bookseller, as being more congenial to the literary turn of his mind. His detached pamphlets were afterwards published by him in the year 1721, in one volume 4to, which was encouraged by a very liberal subscription. The first volume of his well-known collection, the *Tea-table Miscellany*, was published in 1724, and ran through twelve editions in a very few years. He soon afterwards published what is called the *Evergreen*, being a collection of Scotch poems written by ingenious poets prior to the year 1600. In 1725 appeared his *Gentle Shepherd*, part of which, called *Patie and Roger*, was printed in 1721, and *Jenny and Maggy* in 1723, the great success of which induced him to form them afterwards into a regular drama.

In the year 1728 he published a second volume of his poems, which was afterwards reprinted in 8vo. These performances so rapidly enlarged the circle of his fame and reputation that in 1731 an edition of his poetical works was published by the booksellers of London, and two years afterwards they appeared at Dublin. From his shop opposite to Niddry Street he removed to one at the east end of the Luckenbooths. In this shop he continued to sell and lend out books until he was far advanced in years; and we have reason to believe that he was the first person who established a circulating-library in Scotland. His collection of *Fables* appeared in 1730, after which period he may be said to have almost discontinued the occupation of author. Such, however, was his enterprising spirit that he built, at his own expense, the first theatre for dramatical performances ever known in Edinburgh, which took place in what is called Carrubber's Close, in the year 1736; but he did not long enjoy his character of manager, for the magistrates of Edinburgh required him to shut it up, as an act of Parliament prohibited all such amusements without a special license and his Majesty's letters-patent. It is generally understood that he relinquished the trade of bookseller about the year 1755, being then sixty-nine years of age, and lived the remainder of his days in a small house erected by himself on the north side of the Castlehill. A scorbutic complaint, attended with excruciating pain, deprived him of his teeth, and, after corroding one of his jawbones, put a period to his existence on the 7th of January 1758, in the seventy-third year of his age. He was buried in the Greyfriars Churchyard, Edinburgh.

Ramsay possessed a very considerable share of poetical genius. Of this, his *Gentle Shepherd*, which will continue to be admired as long as the language in which it is written shall be understood, and especially by the natives of North Britain, to whom only the peculiarities of dialect by which it is distinguished can be familiar, affords the best proof. Some of his songs may contain far-fetched allusions and childish conceits; but many of them are equal, if not superior, in their pastoral simplicity, to productions of a similar nature in any other language. Some of the imitations of the ancients by this poet are extremely happy; and several of his tales have all the excellences that belong to that species of composition. But of a great proportion of his other productions it may be pronounced with truth that they are mere prosaic compositions, filled with the most commonplace observations, and destitute even of the ornament of smooth versification and correct rhymes. A complete edition of his works, with a *Life* written by the late George Chalmers, was published in 2 vols. 8vo, 1800. A reprint of *The Gentle Shepherd*, with some account of the author's life, has recently been brought out in Edinburgh, in 1856.

The poet's son Allan attained to considerable eminence as a portrait-painter. (See Chambers's *Biographical Dictionary of Distinguished Scotsmen.*)

RAMSAY, *Andrew Michael*, generally known by the name of the *Chevalier Ramsay*, a polite Scottish writer, was descended of a respectable family, and was born at Ayr in 1686.

He studied at the Edinburgh university, where he was distinguished for his industry and abilities. His talents and learning recommended him as a tutor to the son of the Earl of Wemyss; after which, conceiving a disgust for the religion in which he had been educated, he in the same humour reviewed other Christian churches, and, finding none to his liking, rested for a time in Deism. Whilst he was in this uncertain state of mind he went to Leyden, where, falling into the company of Poiret, a mystical divine, he received the infection of mysticism, which prompted him to consult Fénélon, the celebrated archbishop of Cambray, who had imbibed principles of the same nature, and who in 1709 gained him over to the Catholic religion. The subsequent course of his life received its direction from his friendship and connection with this illustrious prelate; and being appointed governor to the Duke de Chateau-Thierry and the Prince de Turenne, he was made a knight of the Order of St Lazarus. Ramsay was sent for to Rome by the Chevalier de St George to undertake the education of his children; but on his arrival there in 1724 he found so many intrigues and dissensions astir, that he obtained the chevalier's leave to return to Paris. He died in 1743, in the office of intendant to the Duke of Bouillon, Prince de Turenne. His works are,—*History of the Life and Works of M. Fénélon, Archbishop of Cambray*, in French and English, 1723; *A Philosophical Essay upon Civil Government*, London, 1721, afterwards republished under the title of *An Essay on Politics; The Psychometre, or Reflections upon the Different Characters of the Mind; The Travels of Cyrus*, in French and English, 1727, 2 vols., and 4to, 1730, written with much elegance, but too much overloaded with erudition and reflection; *The History of Viscount Turenne, Marshal of France*, in French and English; *The Philosophical Principles of Natural and Revealed Religion*, 2 vols. 1749, printed at Glasgow after the author's death.

RAMSDEN, Jesse, a distinguished optician, was the son of an innkeeper, and was born near Halifax in Yorkshire in 1735. His love for mathematical studies began to appear while he was attending a school in his native county. A period of apprenticeship to a cloth-worker in Halifax did not extinguish it. At the age of twenty-four he was found in London, a mathematical and philosophical instrument-maker, skilful in hand and intelligent in head. His growing excellence soon enabled him to open a shop for himself, and to commence a successful business. A sextant invented shortly before 1766 was the first of a series of improved mathematical instruments which issued from his establishment. There followed at intervals a dividing-machine, a theodolite, an equatorial, a telescope, a mural quadrant, a micrometer, and several minor inventions. On account of these services to science, Ramsden was held in high estimation towards the close of his life. At his death in 1800 he was a member of the Royal Society, a fellow of the Imperial Academy of St Petersburg, and the wearer of a Copley medal.

RAMSEY or Ramsay, a market-town of England, county of Huntingdon, on a tongue of high land stretching into the fens near Ramsey Mere, a lake now partially drained, 12 miles N.N.E. of Huntingdon and 69 N. of London. It consists of two streets crossing at right angles, and has a small stream running through the middle of it. Most of the houses are old and built of brick, but many elegant ones have recently been erected. A fine old church, partially exhibiting the transition from the Norman to the early English architecture, is the chief ornament of the town, and is conspicuous for its embattled tower. A ruinous but richly-sculptured gateway is the only remnant of a once famous and wealthy abbey. Places of worship for various denominations, several schools, and a literary institution, are to be found here. The people are mostly engaged in farming. Pop. 4645.

Ramsey or *Ramsay*, a seaport on the N.E. coast of the Isle of Man, 17 miles N.N.E. of Douglas. It is irregularly built; but has wide streets, and contains several churches, a grammar school, and a court-house, where most of the law courts for the north of the island are held. The anchorage in the bay is good, and there is a pier and lighthouse. Herring fishery is a productive source of profit, and corn and provisions are exported. Pop. 2701.

RAMSGATE, a seaport and market town of England, in the county of Kent, at the S.E. corner of the Isle of Thanet, 15 miles E.N.E. of Canterbury, and 73 E. by S. of London. Its older portion lies in a narrow valley, opening out to the sea, between the chalk cliffs that line the coast, and on which many fine new streets and villas have been erected, commanding a beautiful view. In the older portion, where the streets are narrow and the houses mean, there is a market-house, bank, public library, and other edifices. A large and elegant parish church in the Gothic style, with a lofty tower, a chapel of ease, district church, and places of worship for Baptists, Methodists, Independents, Roman Catholics, and Jews are the chief ecclesiastical buildings in Ramsgate. Education is afforded by various schools; the places of amusement include a theatre, assembly-rooms, and baths; and for charitable purposes there are an hospital and a dispensary. Ramsgate has for a long time been resorted to as a sea-bathing place, and indeed its prosperity is chiefly owing to this circumstance. The harbour, which is formed by two piers, and has an area of 48 acres, is the most important feature of the place, and one of the finest works of the kind in the country. It is formed by two piers, built of Portland and Purbeck stone and Cornish granite. The eastern pier is nearly 3000 feet long, the western about half that length, having on it a lighthouse. For repairing ships there are here a dry dock and a slip. The number of sailing-vessels registered at the port, December 31, 1857, was 103, tonnage 5115; of steamers 1, tonnage 10. In the year 1857 there entered coastwise at Ramsgate 388 sailing-vessels, tonnage 30,998; and there cleared 95, tonnage 6118. From foreign ports there entered 29 sailing-vessels, tonnage 3456; and for foreign ports, cleared 16, tonnage 982. In all, there entered 417 vessels, tonnage 34,454; and there cleared 111, tonnage 7100. The trade of the port is very considerable; coal, timber, eggs, and other articles are imported. Ship-building and rope-making are the chief manufactures. Fishing is also an employment to many of the inhabitants. Ramsgate is a member of the Cinque port of Sandwich, and is governed by a deputy appointed by the mayor of that town, and by commissioners under a local act. It was originally a mere fishing-village, with a few mean houses and a wooden pier; but after the Revolution of 1688 some of its inhabitants acquired wealth in the Baltic trade. This business is not, indeed, now carried on here, but it was the first circumstance that led to the prosperity and improvement of the town. The harbour was constructed in 1780–95 by Smeaton, Rennie, and others; and the town was one of the earliest popular watering-places for the Londoners, though at first not so much frequented as Margate. Pop. (1851) 11,838.

RAMUS, Petrus, the Latinized form of the name Pierre de la Ramée, a man celebrated alike by the persecutions of which he was made the object, and by the reforms which he endeavoured to introduce into philosophy, science, and public instruction, was born at the little village of Cuth in Picardy in 1515. His father, Jacques de la Ramée, pursued the humble occupation of a field labourer, but could date back his descent in a few removes to nobility. The boy lost his father at a very early age, and it was reserved for his mother, Jeanne Charpentier, to nurse him in poverty, and teach his young hands early to handle the instrument of toil. Thrift and want combined early to develop his mind; and when only eight years old, we are told of his visiting Paris all alone in pursuit of food and knowledge. Misery pursued the poor child there also, and he was compelled to retrace his steps. Again and again he visited the capital at short intervals, when his maternal uncle, struck with his great perseverance, afforded him temporary shelter. Honoré Charpentier, who pursued the carpenter's craft, could not do more than allow him fairly to commence his studies. Ramus, who had now reached his twelfth year, was endowed by nature with a singularly robust constitution, and entered the college of Navarre in the quality of a domestic. In this position he spent the day in his masters' service, and the night was devoted to study and sleep. He attended the public course given by the Faculty of Arts in 1527, when he left it greatly in love with logic, and with a profound aversion for the manner in which it was taught. The first occasion on which Ramus expressed publicly his dissent from the logic of Aristotle was at his examination for his master's degree. This occurred in 1536, when Ramus had reached his twenty-first year. He chose for his thesis the startling paradox, *Quæcumque ab Aristotele dicta esse, commenticia esse* (All that has been affirmed by Aristotle is a fabrication). A subject so novel placed the judges in the very greatest embarrassment. "The master said it," was no guarantee to Ramus of the truth of a single proposition; and it was entirely in vain that all the peripatetics which Paris contained, united their influence to crush him. The young candidate urged his replies with so much spirit and vivacity, he managed his objections with so much subtlety, and sent them home with so much address, that all Paris was filled with astonishment and admiration. His admission to the rank of Master of Arts was a real triumph.

Having thus emphatically won the right of instructing in the liberal arts, Ramus, in conjunction with Omer Talon, an able professor of rhetoric, and Barthélemy Alexandre, a distinguished Greek scholar, established themselves in the little college of Ave-Maria. When in his twenty-eighth year Ramus published two books in Latin, of which even Joseph Scaliger condescended to extol the style. The title of the one was *Dialecticæ partitiones ad Academiam parisiensem;* of the other, *Aristotelicæ Animadversiones,*—the latter of which in particular subjected its author to incredible persecutions. Hardly had these two books seen the light when the university, by its rector, Pierre Galland, solicited and obtained from the magistrates an arrest for their immediate suppression. Their author was represented as an enemy to religion and to the public peace. After endless jargoning, François I. resolved to bring this quarrel to a close. A chairman and four judges, two of them selected by each party, were to sit in judgment between Ramus and his opponents. The upshot of it was, that Ramus was condemned, on the 1st March 1544, as having "acted rashly, arrogantly, and impudently." He was compelled to leave Paris, and he took up his residence at the college of Presles, where a number of students had taken refuge from the plague, and commenced a course of lectures on rhetoric. He returned to Paris in 1545, the royal decree having been cancelled through the influence of the cardinal of Lorraine. He began a course of mathematics, which he continued till 1551, when Henry II. appointed him professor of philosophy and eloquence in the College of France. The years which followed were the most tranquil of Ramus's life. He wrote a Greek, a Latin, and a French grammar, several treatises on mathematics, logic, and rhetoric. In 1561 Ramus embraced Protestantism, and his logical ardour, as it was said, compelled him to make an invasion into the domain of theology. "Dès ce moment," adds a French biographer, "il fut perdu." Lost or not, Ramus had to flee the halter in the month of July 1562, and found an asylum at the palace of Fontainebleau, the property of Charles IX. The royal protection was not sufficient for his defence, for while absent his house was pillaged and his library destroyed. After the treaty of Amboise in 1563 he resumed his chair in the capital, but did not long enjoy it. Civil troubles in Paris induced him in 1568 to ask permission to travel. He visited a great many towns in Germany and Switzerland, where "the French Plato" (*Gallicus Plato*) was received with much honour. He resided for some time in Bâle, in Heidelberg, in Geneva, and in Lausanne, and taught his logic to the citizens of the three last-mentioned towns. Ramus had found it necessary, during his residence in Paris, strongly to oppose the appointment of one Jacques Charpentier to the mathematical chair of the university, from his profound, yea his avowed, ignorance of the subject. This person never forgave him. On his return to Paris, Ramus fell a victim to Charpentier's revenge during the massacre of St Bartholomew in 1572.

Although Ramus had talent sufficient to overthrow the logic of Aristotle as it was then understood and interpreted, he was unfortunately incapable of raising anything better in its stead. He freed logic from the scholastic subtleties to which it was then applied, but forgot, in re-applying it, to settle its natural limits once and for all. He was not, in short, a profound thinker; he dealt more in rhetoric than in logic. Yet in freeing men's minds from the tyranny of a system he took a decided step in advance of his age, and deserves the gratitude of humanity for so doing. The system of Ramus speedily extended from France to Switzerland, Spain, Germany, Holland, Denmark, and Scotland, and was publicly taught in each of those countries. He left a great number of works, of which a detailed catalogue will be found in *De Petri Rami Vita, Scriptis, Philosophia,* by Waddington Kastus, 8vo, Paris, 1848. Many of the author's works were translated into English and other foreign languages. The partizans of this philosopher are known by the name of Ramists or Rameans.

RAMUSIO, Giambattista, an Italian who was born at Treviso in the Venetian State in 1485, began in the former half of the sixteenth century to edit a collection of the most notable voyages both ancient and modern. The circumstances of his life peculiarly qualified him for such a task. He had travelled in the character of an ambassador through France, Switzerland, and Italy. His acquaintance with history, geography, and languages was great. Many learned foreigners likewise were his friends and correspondents, and could communicate any information he might require. Thus aided, he carried on the work with success. Those parts of his collection which were written in foreign languages he translated into Italian. To those parts which were obscure or incorrect he added explanations and comments from the stock of his own knowledge. The first volume was published at Venice in 1550, under the title of *Raccolta di Navigazioni e Viaggi;* a second followed in 1556; and a third appeared in 1559, two years after the author's death.

RANDERS, a town of Denmark, province of Jutland, on the navigable river Guden or Gudenal, at the head of Rander's Fiord, 22 miles N.N.W. of Aarhuus, and 111 W.N.W. of Copenhagen. It occupies a position that is both very picturesque and strong in a military point of view; and it contains an arsenal, a grammar school, and a large hospital. Much industry is carried on here, especially in the manufacture of hosiery and brandy. The trade is also considerable; and the fishing of salmon is pursued by many of the inhabitants. Pop. (1851) 7738.

RANDOLPH, Thomas, an English poet, was born in Northamptonshire in 1605. He was educated at Westminster and Cambridge, and was very early distinguished by his excellent genius. He gained the esteem and friendship of some of the greatest men of that age, particularly of Ben Jonson, who adopted him as one of his "sons."

He has a good deal of fancy, and he writes melodious verse; but his poetry is bookish, and his love and gallantry is that of a college fellow and a reader of Ovid. He died under thirty in 1634.

His principal works are,—*The Muses' Looking-Glass, a Comedy; Amyntas, or the Impossible Dowry,* a pastoral acted before the king and queen; *Aristippus, or the Jovial Philosopher; The Conceited Pedlar; The Jealous Lovers, a Comedy; Hey for Honesty, down with Knavery, a Comedy;* and several other poems.

RANDOM SHOT, is a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly or point blank. The utmost random of any piece is about ten times as far as the bullet will go point blank. The bullet will go farthest when the piece is mounted at an angle of about 45° above the level range.

RANGE, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges. If the piece lie in a line parallel to the horizon, it is called the *right* or *level range;* if it be mounted to 45°, it is said to have the *utmost range;* and all others between 0° and 45° are called the *intermediate ranges.* (See GUNNERY.)

RANGER, a sworn officer of a forest, appointed by the king's letters-patent, and whose proper business is to walk daily through his bailiwick, to drive back the deer out of the purlieus, and to present all trespasses within his jurisdiction at the next forest court.

RANGOON, a seaport-town of British India, in the province of Pegu, on the left bank of the Rangoon arm of the Irrawaddy, about 20 miles from its mouth, and 62 S. of Pegu. Previous to the great fire which consumed the whole of the town in 1850, it occupied an oblong area along the river's bank, about one mile in length and three-quarters in breadth; but after that catastrophe it was rebuilt on a different site, about a mile from the river, in the form of a square. It was built of bamboos for the most part, and defended by a pagoda on the north side, which formed a sort of citadel. In 1853 and 1855 fresh conflagrations took place; and from the nature of the buildings they proved very destructive. In the re-building of the town, since its last destruction, arrangements have been made by the British authorities for securing not only a proper protection against the recurrence of such devastations by fire, but for providing, by drainage and other measures, for the health and cleanliness of the town. The situation of Rangoon is very favourable to trade; and ship-building is actively carried on. Timber is floated down from the teak forests in the interior, and many vessels of large size have been built here. The town was first built in 1753, by Alompra, the founder of the Burmese monarchy, and from him it derived its name, signifying the "City of Victory." It was taken by the British in the first Burmese war in 1824; but subsequently restored to the native power. In the second war the capture of the pagoda or citadel by General Godwin in 1852 led to the fall of the town; and it passed, along with the province of Pegu, into the hands of the British. Pop. about 20,000.

RANK. See NAVY, § *Personnel.*

RANK AND FILE, the horizontal and vertical lines of soldiers when drawn up for service.

RANTERS. See METHODISTS.

RANZ DES VACHES (Germ. *Kuhreigen*), a simple and beautiful melody which the Swiss herdsmen play on the Alpine horn when driving out and in their herds to the pasture. Consisting, as it does, of a few simple intervals, the effect of it is quite enrapturing when heard among the echoes of the Swiss mountains. The native Swiss are said to be seized with inexpressible longings to return to their native country when they hear it played in a foreign land. This nostalgia or homesickness, as experienced by the Swiss soldier abroad, is elegantly alluded to by Rogers in his *Pleasures of Memory,* part i., p. 19:—

> "The intrepid Swiss, who guards a foreign shore,
> Condemned to climb his mountain-cliffs no more,
> If chance he hears the song so sweet, so wild,
> His heart would spring to hear it when a child,
> Melts at the long-lost scenes that round him rise,
> And sinks a martyr to repentant sighs."

(See *Recherches sur les Ranz des Vaches,* by Tarenne, Paris, 1813: *Sammlung von Schweizer Kuhreigen und Volksliedern,* Berne, 1818; also a *Dissertatio de Nostalgia,* by Th. Zwinger, Basle, 1710.)

RAOUL ROCHETTE, DÉSIRÉ, an eminent French archæologist, was born about 1789 at St Amand, in the department of Cher, and received his education at Bourges. His quick and facile talents soon began to lead him to a high place in the world of letters. At the age of twenty-two he was called to the chair of history in the lyceum at Paris. About four years afterwards he was translated to the same chair in the university of that city. Meanwhile he was commencing to prosecute the science of archæology with great success. The first result of his labours, published in 1815 under the title of *Histoire Critique de l'Establissement des Colonies Grecques,* in 4 vols. 8vo, was favourably received by the public. This achievement stimulated him in his favourite investigations. It is true that a part of his attention was for a while directed to the topography and history of modern Switzerland. But he was soon found making frequent tours of discovery into different European countries, and perfecting his archæological knowledge by the examination of museums and ruined buildings. A part of his researches appeared in 1822 under the title of *Antiquités Grecques du Bosphore Cimmèrien,* and established his fame. So eminent, in fact, did he become, that he was appointed in 1826 to the chair of archæology. The remainder of Raoul Rochette's life was occupied in maintaining that reputation which he had so laboriously gained. He continued to make frequent incursions into the scenes of classical history, and to embody his discoveries in a series of works. His principal publications were,—*Monuments Inédits d'Antiquité figurée Grecque, Etrusque, et Romaine,* in folio, 1828; *Pompei: Choix d'Edifices Inédits,* in folio, 1828; *Peintures Antiques Inédites,* in 4to, 1836; *Mémoires de Numismatique et d'Antiquité,* in 4to, 1840; and *Mémoires d'Archéologie Comparée Asiatique, Grecque et Etrusque,* in 4to, 1848. At his death in 1854, Raoul Rochette was perpetual secretary of the Academy of Fine Arts, and a corresponding member of most of the learned societies in Europe.

RAPE, in law, the carnal knowledge of a woman forcibly and against her will. This, by the Jewish law, was punished with death, in case the damsel was betrothed to another man; and in case she was not betrothed, then a heavy fine of fifty shekels was to be paid to the damsel's father, and she was to be the wife of the ravisher all the days of his life, without the power of divorce which was in general permitted by the Mosaic law.

The Roman law punishes with death and confiscation of goods the crime of ravishment, under which it includes both the offence of forcible abduction, or taking away a woman from her friends, and also the present one of forcibly dishonouring her; either of which, without the other, is in that law sufficient to constitute a capital crime. The stealing away a woman from her parents or guardians, and debauching her, is equally penal by the emperor's edict, whether she consent or be forced; and this in order to take away every opportunity of offending in this from women, whom the Roman law supposes never to go astray without the seduction and arts of the other sex; and therefore, by restraining and making so highly penal the solicitations of the men, they meant to secure effectually the honour of the women. But our English law does not entertain quite such sublime ideas of the honour of either sex as to lay the blame of a mutual fault upon one of the transgressors only; and therefore it is a necessary ingredient in the crime of rape that it must be against the woman's will.

Rape was punished by the Saxon laws, particularly those of Athelstane, with death; which was also agreeable to the old Gothic or Scandinavian constitution. But this was afterwards thought too hard; and in its stead another severe but not capital punishment was inflicted by William the Conqueror, namely, castration and loss of eyes, which continued till after Bracton wrote, in the reign of Henry III. But in order to prevent malicious accusations, it was then the law that the woman should, immediately afterwards, go to the next town, and there make discovery to some credible persons, of the injury she had suffered, and afterwards should acquaint the high constable of the hundred, the coroners, and the sheriffs, with the outrage. This seems to correspond in some degree with the laws of Scotland and Aragon, which require that complaint must be made within twenty-four hours; though afterwards by statute Westm. i., c. 13, the time of limitation in England was extended to forty days. At present there is no time of limitation fixed; for, as it is usually now punished by indictment at the suit of the king, the maxim of law takes place, that *nullum tempus occurrit regi;* but the jury will rarely give credit to a stale complaint. During the former period also it was held for law, that the woman, by consent of the judge and her parents, might redeem the offender from the execution of his sentence by accepting him for her husband, if he also was willing to agree to the exchange, but not otherwise. In the 3d Edward I., by the statute Westm. i., c. 13, the punishment of rape was much mitigated; the offence itself, of ravishing a damsel within age, that is, twelve years old, either with or without her consent, or of any other woman against her will, being reduced to trespass, if not prosecuted by appeal within forty days, and subjecting the offender only to two years' imprisonment, and a fine at the king's will. But this lenity being productive of the worst consequences, it was, in ten years afterwards, 13 Edward I., found necessary to make the offence of forcible rape felony by statute Westm. ii., cap. 34. And by statute 18 Elizabeth, c. vii, it is made felony without benefit of clergy; as is also the abominable wickedness of carnally knowing or abusing any woman-child under the age of ten years, in which case the consent or non-consent is immaterial, as by reason of her tender years she is incapable of judgment and discretion. Sir Matthew Hale is indeed of opinion that such profligate actions committed on an infant under the age of twelve years, the age of female discretion by the common law, either with or without consent, amount to rape and felony, as well since as before the statute of Queen Elizabeth. But that law has in general been held only to extend to infants under ten; though it should seem that damsels between ten and twelve are still under the protection of the statute Westm. i., the law with respect to their seduction not having been altered by either of the subsequent statutes. A male infant, under the age of fourteen years, is presumed by law to be incapable of committing a rape, and therefore, it seems, cannot be found guilty of it. For though in other felonies *malitia supplet ætatem;* yet, as to this particular species of felony, the law supposes an imbecility of body as well as mind. The civil law seems to suppose a prostitute or common harlot incapable of any injuries of this kind; not allowing any punishment for violating the chastity of her who has indeed no chastity at all, or at least has no regard to it. But the law of England does not judge so hardly of offenders as to cut off all opportunity of retreat even from common strumpets, and to treat them as incapable of amendment. It therefore holds it to be felony to force even a concubine or harlot, because the woman may have forsaken that unlawful course of life; for, as Bracton well observes, *licet meretrix fuerit antea, certe tunc temporis non fuit, cum reclamando nequitiæ ejus consentire noluit.* Capital punishment for this offence was abolished by 4 Vict. 1841, and transportation substituted.

RAPHOE, a market-town of Ireland, county of Donegal, in a beautiful situation, amid a rich and well-cultivated country, 3 miles N.W. of Lifford, and 136 N.N.W. of Dublin. It contains a plain cruciform church, formerly the cathedral of the diocese of Raphoe, which is now united with that of Derry. There are also various dissenting places of worship, a free school, national school, and others; a neat market-house, library, dispensary, &c. In the vicinity are the deanery, and a large handsome edifice formerly the episcopal palace. Pop. (1851) 1492.

RAPIN, Paul de, Sieur of Thoyras, an eminent historian, was the son of Jacques de Rapin, and was born at Castres in 1661. He was first educated under a tutor in his father's house, and was afterwards sent to Samur. In 1679 he returned to his father, with a design to apply himself to the study of the law, and was admitted an advocate; but reflecting that his being a Protestant would prevent his advancement at the bar, he soon after resolved to quit the profession of the law, and to apply himself to that of the sword. His father, however, would not consent to the change. The revocation of the Edict of Nantes in 1685, and the death of his father, which happened two months afterwards, made him resolve to come to England; but as he had no hopes of any settlement there, his stay was but short. He therefore went to Holland, and enlisted himself in the company of French volunteers at Utrecht, commanded by M. Rapin, his cousin-german. He attended the Prince of Orange into England in 1688; and the following year Lord Kingston made him an ensign in his regiment, with which he proceeded to Ireland, where he gained the esteem of his officers at the siege of Carrickfergus, and soon received a lieutenant's commission. He was present at the battle of the Boyne, and was shot through the shoulder at the battle of Limerick. He was soon afterwards made captain of the company in which he had been ensign; but in 1693 he resigned his company to one of his brothers, in order to become tutor to the Earl of Portland's son. Having finished this employment, he returned to his family, which he had settled at the Hague, where he continued some years. But as he found his family increase, he resolved to retire to some cheap country; and accordingly removed in 1707 to Wesel, where he commenced his great work the *History of England.* Though he was of a strong constitution, yet seventeen years' application entirely ruined his health. He died in 1725. Rapin wrote in French a *Dissertation sur les Whigs et les Torys.* His *Histoire d'Angleterre* was printed at the Hague in 1726 and 1727, in 9 vols. 4to, and reprinted at Trevoux in 1728, in 10 vols. 4to. This last edition is more complete than that of the Hague. It has been translated into English, and improved, with notes by Tindal, in 2 vols. folio, 1757–59. This performance, although the work of a foreigner, is deservedly esteemed as one of the fullest and most impartial collections of English political transactions extant.

RASGRAD, or Hesarorad, a town of European Turkey, in Bulgaria, in a lofty position overlooking a ravine, on the Ak or White Lern, an affluent of the Danube, 215 miles N.W. of Constantinople. It is a place of considerable trade, standing at the junction of four main roads. Strong in its natural position, it is further defended by a dry ditch and palisade. The Turks were defeated here by the Russians in 1810. Pop. 16,000.

RASK, Rasmus Christian, an eminent scholar and philologist, was born at Brendekilde, in the Island of Fyen or Funen in Denmark, in 1787. He studied at the university of Copenhagen, and early distinguished himself by singular talent for the acquisition of languages. In the year 1808 he was appointed assistant-keeper of the university library, and some years afterwards made professor of literary history. In 1811 he published, in the Danish language, his *Introduction to the Grammar of the Icelandic and other Ancient Northern Languages*, the materials of which were entirely derived from the immense mass of manuscript and printed works which had been accumulated by his predecessors in the same field of research. This grammar appears to have given a fresh impulse to the study of the ancient northern languages, even in Germany. The reputation which Rask acquired by it recommended him to the Arna-Magnæan Institution, by which he was employed as editor of the Icelandic *Lexicon* of Bjorn Haldorsen, which had long remained in manuscript. To this work, which appeared in 1814, Bishop Müller contributed a preface, in which he pronounces a just eulogium on the talents and the spirit of research displayed by the youthful editor. About the same time, Rask who had never been in Iceland, paid a visit to that country, where he remained from 1813 to 1815, during which time he made himself completely master of the language, and familiarized himself with the literature, manners, and customs of the natives. To the interest with which they inspired him may probably be attributed the establishment at Copenhagen, early in 1816, of the Icelandic Literary Society, which was mainly instituted by his exertions, and of which he had the honour to be the first president.

Whilst thus employed, however, he was about to enter upon a more ample field of enterprise. In October 1816 he left Denmark on a literary expedition, which had been fitted out for the double purpose of prosecuting inquiries into the languages of the East, and collecting manuscripts for the University Library at Copenhagen. The King of Denmark having liberally provided him with the requisite means, he proceeded first to Sweden, where he remained two years, in the course of which he made an excursion into Finland, for the purpose of studying the language of that country. Here he published, in Swedish, his *Anglo-Saxon Grammar* in 1817; and during the same year there appeared at Copenhagen, in Danish, an *Essay on the Origin of the Ancient Scandinavian or Icelandic Tongue*, in which he traced the affinity of that remarkable idiom to the other European languages, particularly to the Latin and the Greek. In 1818 he published a second edition, very much improved, of his *Icelandic Grammar*, translated by himself into Swedish; and in the course of the same year he also brought out the first complete editions of Snorrow's *Edda*, and Sæmund's *Edda*, in the original text, along with Swedish translations of both *Eddas*, the originals and the versions occupying each two volumes. From Stockholm he proceeded in 1819 to St Petersburg, where he wrote in German an interesting paper on "The Languages and Literature of Norway, Iceland, Sweden, and Finland," which was published in the sixth number of the Vienna *Jahrbucher*. From Russia, which he traversed, he proceeded through Tartary into Persia, and resided for some time at Tauris, Teheran, Persepolis, and Shiraz. It may be mentioned here, as an instance of his remarkable facility in acquiring languages, that in about six weeks he made himself sufficiently master of the Persian to be able to converse freely in that language with the natives. In 1820 he embarked at Abuschekr, in the Persian Gulf, for Bombay, which he reached in safety; and during his residence there he wrote in English "a Dissertation on the Authenticity of the Zend Language," which he addressed to the governor, the Hon. Mountstuart Elphinstone, and which was afterwards published in the third volume of the *Transactions of the Literary Society of Bombay*. The same production, with corrections and additions, was afterwards deemed worthy of insertion in the *Transactions of the Royal Asiatic Society*. From Bombay he proceeded through India to Ceylon, where he arrived in 1822, and soon afterwards wrote, in English, "A Dissertation respecting the best Method of expressing the Sounds of the Indian Languages in European Characters," which was printed in the *Transactions of the Literary and Agricultural Society of Colombo*. Professor Rask, having at length completed his researches on the scale prescribed, set out for Europe, and reached Copenhagen in the beginning of May 1823, after an absence of nearly seven years. He brought home with him a considerable collection of rare and curious oriental manuscripts, Persian, Zend, Pali, Cingalese, and others, which now enrich the university and royal libraries of the Danish capital.

Notwithstanding all his labours and exertions, this indefatigable scholar scarcely allowed himself an interval of repose. Between the period of his return from the East and that of his death, which occurred far too soon for the interests of philology, Professor Rask published in his native language a *Spanish Grammar* in 1824, an *Italian Grammar* and a *Frisic Grammar* in 1825, a *Treatise respecting the Ancient Egyptian Chronology* in 1827, *the Ancient Jewish Chronology previous to Moses* in 1828, and an *Essay on Danish Orthography* in the same year. He likewise edited an edition of Schneider's *Danish Grammar for the use of Englishmen* in 1829, and superintended the English translation of his *Anglo-Saxon Grammar* by Thorpe in 1830. This last work supplies what had long been a desideratum in English literature. Before its appearance persons whose taste might dispose them to investigate our early vernacular remains had no guides to direct them, and each had to form for himself a grammar and a dictionary of the Saxon. Hickes' was full of blunders, and in these Elstob, Lye, Manning, and others had religiously followed him, superadding their own contingents respectively. Rask's services to comparative philology were very great. He was the first to point out the connection between the ancient Northern and Gothic on the one hand, and of the Lithuanian, Sclavonic, Greek, and Latin on the other. In private life the character of Professor Rask was such as to command admiration and respect. His manners, though somewhat retiring, were mild and gentle, and his morals unimpeachable. His mode of living was simple in the extreme, and his temperance almost that of an anchoret. The habits of study and application which he had acquired in his youth were never laid aside. In company he was diffident, and always expressed himself with modesty; but when the subject involved anything relative to his own history or pursuits, he evinced a reluctance to converse which seemed to grow upon him with years, and almost amounted to a morbid sensibility. His facility in the acquisition of languages was extraordinary; he appeared to gain a knowledge of them by a sort of intuition, and his mind seemed to recollect rather than to learn. In 1822 he was master of no less than twenty-five languages and dialects. His knowledge of English was extensive and correct. He spoke and wrote it with such fluency and precision that Englishmen to whom he was introduced were accustomed to ask him how long he had been in England, considering that such an acquaintance could only be gained by a residence in the country where it was spoken. Rask, in his personal appearance, was thin and spare, but well made; his habits of temperance, regularity, and exercise, had contributed to give him all the appearance of a healthy man, and he seemed destined to attain a ripe old age. He was capable of enduring much fatigue, and even the privation of necessary rest; changes of climate seemed to produce no impression upon his constitution; the scorching sun of India, and the biting frosts of Iceland, were equally braved and disregarded. But, with all this apparent superiority to ordinary infirmities, he fell a victim to consumption, and died at Copenhagen on the 14th of November 1832, in the forty-fifth year of his age. His numerous philological manuscripts were given over to the king's library at Copenhagen. Rask's *Anglo-Saxon, Danish*, and *Icelandic Grammars* have been given to the English public by Thorpe, Repp, and Dasent respectively.

RASSOVA, a fortified town of European Turkey, on the right bank of the Danube, at the place where that river turns suddenly to the north, 38 miles E. by N. of Silistria. Near this begins the line of earth-works called Trajan's Wall, stretching across the isthmus of the Dobrudscha to the Black Sea. Rassova was occupied by the Russians for a short time in 1854. Pop. 8000.

RASTADT, or RASTALL, a fortified town of the grand duchy of Baden, circle of Middle Rhine, on the Murg, not far from its confluence with the Rhine, 14 miles S. of Carlsruhe, and 30 N.E. of Strasburg. The palace, formerly occupied by the margraves of Baden-Baden, a building four storeys high, after the model of the palace at Versailles, is the most conspicuous edifice. It stands on a height, and has a tower surmounted with a gilt statue of Jupiter, and commanding an extensive view. The town is regularly built, and has several churches, a lyceum, and a normal school. Manufactures of tobacco, snuff, cutlery, mathematical and musical instruments are carried on here; and there is a considerable trade. Rastadt was first brought into importance by the Margrave Louis William, who had fixed his residence here in the end of the seventeenth century, it having previously been but a small village. The peace of 1714, which put an end to the war of the Spanish succession, was signed in the palace by Prince Eugene and Marshal Villars. A congress was held here in 1797–9, to negotiate a peace between France and the empire, after which the French ambassadors, Roberjot and Bonnier, were murdered on their return, only a short distance from the town, but by whom it was never ascertained. A monument now marks the place. At Rastadt the insurrection in Baden in 1849 first broke out; and the insurgents, after a three weeks' siege, were obliged to surrender at discretion to the Prussians. Pop. 7284.

RASTALL, JOHN, a printer and miscellaneous writer, was born in London probably about the end of the fifteenth century, and educated at Oxford. Returning from the university, he settled in the metropolis and commenced printer, "then esteemed," says Wood, "a profession fit for any scholar or ingenious man." He married the sister of Sir Thomas More, with whom, we are told, he was very intimate, and whose writings he strenuously defended. From the title-page of one of his books, he appears to have lived in Cheapside, at the sign of the Mermaid. He died in the year 1536; and left two sons, William and John; the first of whom became a judge in Queen Mary's reign, and the other a justice of peace. The subject of the present article was a zealous Papist; but Bale says that he changed his religion before his death. He wrote *Natura naturata*, which Pits calls a copious and ingenious comedy, describing Europe, Asia, and Africa. *The Pastyme of the People; the cronycles of diverse realmys, and most especially of the realm of England, brevely compiled and emprinted in Cheapesyde, at the sign of the Mermaid, next Pollysgate, cum privilegio*, folio. It was reprinted in 1811 in the *Collection of English Chronicles*. *Ecclesia Johannis Rastall*, 1542, was one of the prohibited books in the reign of Henry VIII. He also wrote *Legum Anglicanarum vocabula explicata*, French and Latin, London, 1567, 8vo.

RASTENBURG, a town of Prussia, in the province of Prussia, and circle of Königsberg, on the Guber, 55 miles S.E. of Königsberg. It is distinguished by the high, red roofs of the houses; and contains a castle, several churches, a gymnasium, &c. Linen is woven here, and forms the principal article of trade. Pop. 4805.

RAT. See MAMMALIA.

RATAFIA, a fine spirituous liquor prepared from the kernels and other parts of several kinds of fruits, particularly cherries and apricots. Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has long been kept; then adding to them the kernels of cherries, with strawberries, sugar, cinnamon, white pepper, nutmeg, cloves, and to twenty pounds of cherries ten quarts of brandy. The vessel is left open ten or twelve days, and then stopped close for two months before it is tapped. Ratafia of apricots is prepared in two ways,—namely, either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy, with sugar, cinnamon, mace, and the kernels of apricots, infusing the whole for eight or ten days, then straining the liquor, and putting it up for use; or by infusing the apricots, cut in pieces, in brandy for a day or two, passing it through a straining-bag, and then putting in the usual ingredients. The French excel in this species of distillation.

RATCHET. See CLOCK AND WATCH WORK, § *Going Barrels*.

RATES. See NAVY, § *Matériel*.

RATHANGAN, a market-town of Ireland, county of Kildare, on the Little Barrow, 5 miles N. by W. of Kildare, and 31 W.S.W. of Dublin. It is pretty well built, and contains a handsome parish church; various other places of worship, two schools, a dispensary, and several large flour-mills. There are hardly any manufactures or trade here. Pop. (1851) 1004.

RATHDOWNEY, a market-town of Ireland, Queen's County, on an affluent of the Nore, 19 miles S.W. of Maryborough. It has a good parish church, Methodist and Roman Catholic chapels, two schools, a barrack, and a dispensary. In the parish there are, besides other remains, those of an abbey and of three castles. A brewery and a boulting-mill are the only manufactories. Pop. (1851) 1192.

RATHENOW, or RATHENAU, a town of Prussia, in the province of Brandenburg and circle of Potsdam, on the Havel, 45 miles W. of Berlin. It contains a church with a newly-erected Gothic tower, a gymnasium, and a girls' school. There is also a monument and a statue of the elector Frederick-William. Among the manufactures, the most important is that of optical instruments; fishing, brewing, distilling, and navigation, give employment to many of the people. A victory was gained here in 1675 by the troops of Brandenburg over the Swedes. Pop. 6432.

RATHKEALE, a market-town of Ireland, county of Limerick, on the Deel, 16 miles S.W. of Limerick, and 136 S.W. by W. of Dublin. Many of the houses are well built; and there are a parish church, Roman Catholic and other places of worship, a court-house, jail, several schools, hospital, dispensary, and workhouse. The inhabitants are mostly employed in farming, and there is a considerable retail trade. The ruins of an old priory and of two castles are to be seen here. Rathkeale derived much advantage from a colony of German Protestants who settled here in the beginning of the eighteenth century. Pop. (1851) 3029.

RATIBOR, a town of Prussia, in the province of Silesia and government of Oppeln, on the left bank of the Oder, 40 miles S.S.E. of Oppeln. It is walled, entered by four gates, and defended by a castle. There are here a court of appeal for Upper Silesia, several churches, a gymnasium, and other schools, several hospitals, &c. Manufactures and trade are actively carried on; and much-frequented markets are held for corn, cattle, wool, flax, and hemp. Pop. 9691.

RATIO. See GEOMETRY, § on *Proportion*.

RATION, a portion of ammunition, bread, drink, and forage, distributed to each soldier in an army for his daily subsistence. The horse have rations of hay and oats when they cannot go out to forage.

RATIONALISM, in its widest acceptation, is applicable to all who follow the dictates of reason, whether in their speculative or practical life. In its more restricted signification it is applied specially to that system of religious opinion whose final test of truth is placed in the direct assent of the human consciousness, whether in the form of logical deduction, moral judgment or religious intuition, by whatever previous process these faculties may have been raised to their assumed dignity as arbitrators. The rationalist, as such, is not bound to maintain that a divine revelation of religious truth is impossible, nor even to deny that it has actually been given. He may admit the fact of a revelation, and may accept certain portions of it as of permanent authority; but he assigns to the higher tribunal of his consciousness the right of determining what is essential to religion and what is not.

RATISBON (Germ. *Regensburg*, Fr. *Ratisbonne*), a town of Bavaria, in the upper palatinate, on the right bank of the Danube, here crossed by an ancient stone bridge, at its confluence with the Regen, 65 miles N.N.E. of Munich. It has an antique and somewhat dull appearance, as it has greatly fallen off from its former size and splendour. The old walls which surround it are in a dilapidated condition, and the ditches filled up. Entrance is obtained by six gates into the town, where the streets, narrow and crooked, though clean, are lined with old-fashioned stone buildings. Several loop-holed embattled towers rise from the houses to remind the spectators of the ancient turbulent times; and in the street of the ambassadors there are many memorials of the days when its splendid mansions were occupied by the representatives of great monarchs and nations. The arms of various countries decorate many of the houses, among which are the eagle of Austria and the lion of St Mark. The Gothic cathedral of St Peter, though both of its towers are unfinished, is one of the masterpieces of German architecture. It was begun in 1275, and left off in 1634. The ground plan is peculiar, as the lower storey has no transepts, but only the upper. The western front is extremely beautiful, and richly adorned. In the interior are many fine statues and works of art; among the rest, the high altar of solid silver. From the summit of the building a beautiful and extensive view is obtained over the course of the Danube, with the chain of the Alps in the distance. Within the cathedral inclosure are the remains of two more ancient churches, curious and interesting to the antiquarian. There are numerous other churches in the town, but few of them possess much interest. A gloomy and irregular old building near the cathedral is the town-hall, the meeting-place of the German Diets from 1663 till 1806. In the assembly-hall are still to be seen the seats and benches which are said to have been used. The building also contains dungeons and a torture chamber; in the latter, directly below the hall of the Diet, is the most perfectly preserved collection of instruments of cruelty that exists in Europe. A large building, formerly the Benedictine convent of St Emmeran, is now the residence of the Count of Thurn and Taxis. In the garden belonging to it stands a monument to Kepler, who died at Ratisbon in 1630, and is buried in the adjacent churchyard. The town contains, besides the buildings already mentioned, a theatre, public library, picture gallery, collection of antiquities; lyceum, gymnasium, and other schools; hospital, infirmary, orphan and blind asylums, &c. The manufactures include beer, brandy, tobacco, leather, wax-candles, porcelain, earthenware, paper, cotton, steel, brass, &c. Ship-building is actively carried on, and there is a considerable trade and navigation on the Danube; salt, timber, and corn, being the chief articles of commerce. In the vicinity of Ratisbon stands the Walhalla, a building after the model of the Parthenon at Athens, containing busts and monuments of celebrated Germans from the earliest period. It was founded by King Lewis of Bavaria in 1830, and completed in 1842; a magnificently-adorned building, but, as a temple of Fame, not by any means so impressive as the time-hallowed fanes of other countries. It stands on a hill commanding towards the east, a view of the dark slopes of the Bavarian Forest on the north of the Danube, and the rich plain of Straubing on the south, with the ruin-crowned heights of Donaustauf, and the towers of Ratisbon to the west, and in clear weather the distant Alps to the south. Ratisbon is a town of great antiquity, and was a place of some importance under the Romans. With the exception of one square tower, said to be of Roman origin, there are no remains of this period. The first German emperor, Louis the German, fixed his residence here; and the town was afterwards the seat of the dukes of Bavaria, and the capital of that country. Frederick Barbarossa, in the twelfth century, made Ratisbon immediately dependent on the empire, and as such it remained till 1803, when it was given to the Archbishop of Mentz. The town enjoyed great prosperity during the middle ages; but, like Augsburg and Nuremberg, it fell into decay after the discovery of the Cape of Good Hope. In 1809 it passed again into the possession of Bavaria. Pop. 25,000.

RATLINES, or, as the sailors call them, *ratlins*, those lines which form the ladder-steps to the shrouds of a ship.

RATTANS, commercially *rattan-canes*, are the whip-like prolongations (*flagelli*) of the petioles of *Calamus Roxburghii*, Griffiths, the *C. Rotang* of Roxburgh and other species (Nat. Ord. *Palmaceæ*). These *flagelli* are often of very great length, and as they are armed at their extremities with long sharp prickles, when pushed amongst the foliage of other trees they serve as tendrils to these climbing palms. The greater portion of the *flagellum* is smooth and glossy, with a thick silicious coating having the appearance of varnish, and being very indestructible. They are collected in Bengal, along the Coromandel coast, in Java, and in China, in vast quantities, and are used very extensively for a great variety of purposes in all parts of the peninsula of India, from which they are largely exported to all parts of the world. Their great strength and flexibility, their cylindrical form, the ease with which they split, &c., render them applicable to a variety of purposes. The Hindus and Chinese make hats, shoes, chairs, bedsteads, baskets, sieves, and other useful articles of them. They likewise use them as ropes for binding their wooden houses together, and form a great variety of mats from them. The Chinese use them to a great extent instead of cord for tying round their tea-chests. In Europe they are chiefly used in forming the bottoms of chairs and stools, and as a cheap substitute for whalebone. The imports in 1858 were 8,901,600 rattans. They usually come in bundles of about fifty in each, the canes being about 16 feet in length, and once bent in the bundle. (T. C. A.)

RAUCH, CHRISTIAN, one of the greatest sculptors of modern times, was born at Arolsen, in the principality of Waldeck, on the 2d of January 1777. The opening career of the young artist was attended with considerable difficulty. His parents were poor, and could not afford to place him under efficient masters. His first instructor, Valentin of Arolsen, taught him little else than the art of sculpturing grave-stones. Professor Ruhl of Cassel could not give him much more. A wider field of improvement opened up before him when he removed to Berlin in 1797; but poverty still hampered all his efforts. He was obliged to earn a livelihood by becoming a royal lacquey, and to reserve the prosecution of his favourite art for his spare hours. The genius of Rauch, however, soon forced itself into notice, and recommended him to several influential individuals who were able to give him assistance. Queen Louisa surprising him one day in the act of modelling her fair features in wax, sent him to study at the Academy of

Art. Not long afterwards, in 1804, Count Sandrecky gave him the means to go and complete his education at Rome. There also he found both aid and encouragement. William Von Humboldt directed his attention to the antique. Canova and Thorwaldsen advised and stimulated him in that study. Under such propitious patronage the young sculptor made rapid progress. Among other works, he executed bas-reliefs of "Hippolytus and Phædra;" "Mars and Venus wounded by Diomede," and a "Child Praying."

It was in 1811 that Rauch entered upon the eminent part of his career. Commissioned in that year to execute a monument for Queen Louisa of Prussia, he summoned up all his strength and industry for the arduous task. It is said that he shut himself up from all intercourse with the world until, by unwearied meditation and experiment, he had caught and embodied the features of his departed patroness. The statue, representing the queen in a sleeping posture, was placed in a mausoleum in the grounds of Charlottenburg, and procured great fame for the artist. Commissions for portraits came pouring in upon him. The consummate tact with which he seized individual characteristics, and the artistic manner in which he treated them, established at once his reputation. The erection of all public statues came to be entrusted to him. He began to execute that long series of representations of great Germans in which his genius is exhibited to full advantage. As years passed by, statesmen, patriots, and men of genius, some colossal and others of the ordinary size, continued to come forth from his studio. In course of time almost every important town throughout the country possessed a bust of some worthy fresh and vigorous from his matchless chisel. There were, among others, Blucher at Breslau, King Maximilian at Munich, Pastor Franke at Halle, Albert Dürer at Nürenberg, Luther at Wittenberg, and the Grand Duke Paul Frederick at Schwerin. At length he reached the climax of his efforts, by commencing in 1840 a colossal monument at Berlin to Frederick the Great. This work was inaugurated with great pomp, and in the presence of a vast assemblage, in May 1851, and has ever since been regarded as one of the grandest masterpieces of modern sculpture. On a granite pedestal 25 feet in height stands the colossal equestrian statue of the king. His plain, pinched features, and his grotesque costume, are given with historical exactness, without impairing the artistic effect. An air of resistless majesty ennobles the mean countenance, and a bold and skilful treatment hides the absurdity of the garb. Nor are the representations on the pedestal less correct or less successful. On each of the four faces designs in high relief, of the size of life, and executed after authentic portraits, busts, or medals, appear lively groups of the generals, statesmen, and great men of the reign. Beneath these figures are tablets bearing the names of other noted Prussian contemporaries. Above are female forms of Justice, Strength, Wisdom, and Moderation, interspersed with emblematic bas-reliefs of the principal periods of the monarch's career. In fact, the entire monument is a vivid history in stone of the life and reign of Frederick the Great.

These numerous labours of Rauch were rewarded by a happy old age. The matchless excellence of his masterpiece had been recognised throughout the world. Princes decorated him with honours. All the academies of Europe enrolled him among their members. Especially did his own sovereign and countrymen regard him with proud affection and respect. Of late years his fine form, the very embodiment of elevated and venerable genius, was an object of interest at the court-balls of Berlin. Nor did he take less pleasure than he had ever done in the prosecution of his art. As he said himself, "his working-room was his home." A statue of Kant for Königsberg, and a statue of Thaer for Berlin, occupied his attention during some of his last years; and he had just finished a model of "Moses praying between Aaron and Hur," when the illness attacked him which eventually carried him off on the 3d December 1857.

RAVAILLIAC, or RAVAILLAC, FRANÇOIS, the assassin of Henri IV. of France, was born at Angoulême, about 1578, and was at the time of his execution about thirty-two years of age. Ravaillac was the son of humble parents, his father being one of those inferior retainers of the law to whom the vulgar give the name of pettifoggers, a profession to which his son had also been bred. He taught a school for some time, and seems to have been imprisoned for debt, which greatly affected his mind. His distress was so great that he had much ado to live. When he was seized for the murder of the king, he was very loosely guarded, and all were permitted to speak with him who pleased. He was removed next day from the house of Espernon to the Conciergerie, the proper prison of the Parliament of Paris. When he was first interrogated, he answered with great boldness, that he had done it, and would do it if it were to be done again. When he was told that the king, though dangerously wounded, was living, and might recover, he said that he had struck him home, and that he was sure he was dead. He persisted in the most solemn asseverations that he had no accomplices, and that nobody had persuaded him to the fact. He appeared surprised at nothing so much as at the universal abhorrence of the people, which, it seems, he did not expect. When he was put to the torture, he broke out into horrid execrations, and always insisted that he did the act from his own motive, and that he could accuse nobody. On the day of his execution, after he had made the *amende* before the church of Nôtre Dame, he was carried to the Grève; and, being placed upon a scaffold, was tied to a wooden engine in the shape of a St Andrew's cross. The knife with which he did the murder being fastened in his right hand, it was first burned in a slow fire; then the fleshy parts of his body were torn with red-hot pincers, and melted lead, oil, pitch, and rosin poured into the wounds. The people refused to pray for him; and when, according to the sentence that had been pronounced upon him, he came to be dragged to pieces by four horses, one of those that were brought appearing to be but weak, a spectator offered his own, with which the criminal was much moved. He was very earnest for absolution, which his confessor refused, unless he would reveal his accomplices. "Give it me," said he, "upon condition that I have told the truth;" which the priest eventually did. His body resisted the force of the horses; and the executioner cut him into quarters, which the people dragged through the streets. There has just been published *Le Proces du tres Meschant et Detestable Parricide François Ravaillac*, by Auguste Aubry, Paris, 1859, compiled from the original MSS. of the trial.

RAVELIN. See FORTIFICATION.

RAVENGLASS, a seaport and market town of England, in the county of Cumberland, 42 miles S.S.W. of Carlisle. It stands on an inlet of the sea, where the Esk, Irt, and Mite unite, and commands a view of the Welsh mountains and the Isle of Man. Oysters are obtained along the coast, and there is a considerable coasting trade in coal, timber, and corn. Pop. (1851) of the parish of Muncaster, in which it is included, 623.

RAVENNA, a town of the Papal States, capital of a delegation of the same name, on the left bank of the Montone, 43 miles E. by S. of Bologna. It stood originally on the coast; but as early as the fifth century the alluvial deposits brought down by the Po had begun to encroach upon the sea, from which it is now about 4 miles distant. This space is now occupied by a portion of that celebrated pine forest, perhaps the most ancient in Italy, which covers the flat sandy ground along the Adriatic for about 25 miles. It furnished timber for the Roman fleets, and afterwards for those of Venice; and it has been rendered classic ground by the genius of Dante, Boccaccio, Dryden, and Byron. The town is inclosed by earthen ramparts about 3 miles in circuit, but it has miserably shrunk from its former dimensions; its palaces are deserted of their greatness, and grass grows in its broad and once busy streets. The cathedral, built by Orso, Archbishop of Ravenna, in the fourth century, has been rebuilt in modern times; so that the only relic of the original edifice is the cylindrical campanile, which resembles the Constantinopolitan minarets. In the interior there are, among other works of art, two of the finest of Guido's paintings. The baptistery, of an octagonal form, is of nearly the same date as the church, and is detached from it. It contains many well-preserved treasures of early Christian art. The basilica of San Vitale is a splendid octagonal building in the pure Byzantine style, after the model of St Sophia at Constantinople. It was consecrated in 547, and was imitated in the church of Charlemagne at Aix-la-Chapelle. Of the other churches in the town, many possess much interest from their antiquity, their architecture, or the paintings and sculptures which they contain. Indeed, it is at Ravenna that the early Christian monuments are to be seen in the greatest perfection; they are not, as in Rome, mixed with the remains of an earlier paganism; nor as in Constantinople, which in architecture this city much resembles, altered by the introduction of the Moslem religion and rule. Of the once splendid palace of Theodoric nothing now remains but a single wall, adorned with marble pillars. The mausoleum of the Gothic monarch, about a mile outside of the town, is a round marble edifice, with a solid dome weighing more than 200 tons. On its flat summit the urn with the royal ashes is said to have lain. The building, now a church, has been split by lightning, and sunk some feet in the earth. But the most celebrated tomb in Ravenna is that of Dante, whose ashes, inclosed in a marble sarcophagus, lie in a small square building surmounted by a cupola, and ornamented not with very good taste. Near this spot is the house where Byron lived for more than two years. Among the palaces of the town, the most interesting is that of the archbishop, the chapel of which has been preserved untouched from the fifth century. The public library contains upwards of 40,000 volumes and 700 MSS.; among the latter, is a celebrated one of Aristophanes, and an illuminated one of Dante on vellum. The museum and the academy of fine arts are both rich in their respective objects. There are also various private collections of paintings, a theatre, and other establishments. The only manufacture carried on here is that of silk, and this only to a very small extent. The trade too is almost extinct. The origin of Ravenna is lost in obscurity; it is said to have been a Thessalian colony, but was afterwards given over to the Umbrians, who retained possession of it till it was conquered by the Romans. What time this took place does not appear; the name is not mentioned till the time of the civil wars, when it seems to have been a place of much importance. In the time of Augustus it stood on the coast, in the midst of marshes, and was built on piles, intersected by canals; so that it must then have resembled the modern Venice. That monarch, making Ravenna the station of his Adriatic fleet, formed a harbour called Portus Classis, about 3 miles to the south, and connected it with the Po by a canal which passed through the town. From this epoch the station of the Roman fleet continued to be here, and the city rose to a great degree of prosperity, especially as a military post. In 404 Honorius established his residence here, and it was under him and his successors the imperial city of the West. Besides its strong position, the fortifications with which it was defended secured Ravenna against the attacks of the Goths for a considerable time. Theodoric, king of the East Goths, overthrew in 489 Odoacer, who had established himself there after the fall of the Western Empire, and made Ravenna the capital of a new kingdom. Fifty years later, Belisarius compelled the surrender of the city; and his successor Narses obtained the government of Italy, under the title of Exarch of Ravenna. This exarchate lasted for 185 years, till in 754 the Lombards, under Astolphus, driving out Eutichius, the last exarch, made Ravenna the metropolis of their kingdom. But their designs against Rome brought upon them the armies of Pepin and Charlemagne, who re-conquered Ravenna, and gave it as a temporal possession to the Papal See. Many civil wars and tumults took place in the subsequent ages; and in 1441 the people placed themselves under the protection of Venice. In 1509 Ravenna was restored to the Pope, and made the capital of the Romagna, governed by his legates. Shortly after, a French army under Gaston de Foix invaded Italy, and encountered the Spanish and Papal troops near Ravenna. One of the most bloody engagements recorded in history took place; the French were victorious, but their brave commander fell in a desperate assault on the retreating foe. Ravenna was once more taken from the Pope by the French in 1790, but afterwards restored. Pop. about 18,000.

The delegation, bounded on the N. by that of Ferrara, E. by the Adriatic, S. by the delegation of Forli, and W. by that of Bologna and by Tuscany, has an area of 674 square miles. The country slopes towards the N. and E. from the Apennines and their branches in the interior; and along the coast is marshy and unhealthy, though the inland portions are fertile and salubrious. Salt, corn, hemp, flax, wine, and cattle are the chief products of the country. Pop. (1853) 175,994.

RAVENSBURG, a town of Wurtemberg, circle of the Danube, in the midst of vine-clad hills, on the Schussen, 22 miles E.N.E. of Constance. It has an antique appearance, and is encircled with embattled walls and towers of various form. From the Veitsburg, a height once occupied by a castle of the Guelph family, a magnificent view is obtained of the Lake of Constance and the Swiss Alps. The town contains a town-hall, many churches, convents, hospitals, &c. Manufactures of beer, silk, flax, worsted, paper, and other articles are carried on. The trade too is very extensive. Pop. 5500.

RAWITSCH, or RAWICZ, a town of Prussia, province and 55 miles S. of Posen. It is well built, and encircled with walls and ditches, and contains a handsome town-hall, Protestant and Roman Catholic churches, a gymnasium and other schools, a jail, &c. The manufactures consist of woollen and cotton cloth, leather, hats, and tobacco; and there are also spinning-mills. Some trade is carried on in corn and wool. Charles XII. of Sweden had his winter quarters here in 1704. Pop. 9532.

RAY, JOHN, a celebrated naturalist, was the son of Roger Ray, a blacksmith, and was born at Black Notley in Essex in 1628. He received the rudiments of learning at the grammar school of Braintree; and in 1644 was admitted into Catharine Hall, Cambridge, whence he afterwards removed to Trinity College in that university. He took the degree of Master of Arts, and became at length a senior fellow of the college. He was chosen Greek lecturer at the age of twenty-three, and two years later mathematical tutor to his college. His intense application to his studies having injured his health, he was obliged at his leisure hours to exercise himself by riding or walking in the fields, which led him to the study of plants. He noted from Johnson, Parkinson, and the *Phytologia Britannica*, the places where curious plants grew; and in 1658 he rode from Cambridge to the city of Chester, whence he proceeded to North Wales, visiting many places, and amongst others the famous hill of Snowdon, and returning by Shrewsbury and Gloucester. In 1660 he published his *Catalogus Plantarum circa Cantabrigiam nascentium*, and the same year he was ordained deacon and priest. In 1661 he accompanied Francis Willughby and others, in search of plants and other natural curiosities, to the north of England, and Scotland; and the next year he made a western tour from Chester, through Wales, to Cornwall, Devonshire, Dorsetshire, Hampshire, Wiltshire, and other counties. He afterwards travelled with Willughby and other gentlemen through Holland, Germany, Italy, France, and made several tours in England, and was admitted fellow of the Royal Society. In 1672 his friend Willughby died, in the thirty-seventh year of his age, at Middleton Hall, his seat in Warwickshire, to the great loss and grief of Ray himself, his friends, and all good men who knew him. As there existed the closest and most sincere friendship between Willughby and Ray from the time of their being fellow-students, Willughby not only confided in Ray in his lifetime, but also at his death; for he made him one of the executors of his will, and charged him with the education of his sons, Francis and Thomas, leaving him at the same time an annuity of L.60 per annum. The elder being not quite four years of age, Ray, as a faithful trustee, undertook their instruction, and for their use compiled his *Nomenclator Classicus*, which was published the same year. Francis, the elder, dying before he became of age, the younger became Lord Middleton. Not many months after the death of Willughby, Ray lost another of his best friends, Bishop Wilkins, whom he visited in London on the 18th of November 1672. In June 1673 Ray married a daughter of Mr Oakley of Launton in Oxfordshire. Towards the end of this year came forth his *Observations made in Foreign Countries*, to which was added his *Catalogus Stirpium in exteris Regionibus observatarum;* and about the same time appeared his *Collection of Unusual or Local English Words*, which he had made in his travels through the counties of England. After having published many books upon subjects foreign to his profession, and among which was his *Collection of Proverbs*, published in 1672, he at length resolved to appear in the character of divine. He published his excellent demonstration of the being and attributes of God, entitled *The Wisdom of God manifested in the Works of the Creation*, 1697, 8vo. The rudiments of this work were read in some college lectures; and another collection of the same kind he enlarged, and published under the title of *Three Physio-theological Discourses concerning the Chaos, Deluge, and Dissolution of the World*, 1692, in 8vo. Ray died in 1705. He was modest, affable, and communicative, and distinguished by his probity, charity, sobriety, and piety. He wrote a great number of works, the principal of which, besides those already mentioned, are:—

Catalogus Plantarum Angliæ; Dictionariolum Trilingue secundum locos communes; Historia Plantarum Species hactenus editas, aliasque insuper multus noviter inventas et descriptas complectens, 3 vols.; *Methodus Plantarum nova, cum Tabulis*, 8vo, and several other works on plants; *Synopsis Methodica Animalium Quadrupedum et Serpentini generis*, 8vo; *Synopsis Methodica Avium et Piscium; Historia Insectorum, opus posthumum; Methodus Insectarum; Philosophical Letters.*

Memorials of John Ray have been written by Dr Derham, by Sir J. E. Smith for Rees' *Cyclopædia*, and by Cuvier and Dupetit Thouars for the *Biog. Univ.* (See those biographies, collected and published for the "Ray Society" by Dr Edwin Lankester.)

RAYMOND of Sebonde (written also *Sabonde, Sabunde, Sebon, Sebond, Sebeyde, Sabiende*, and *Sebeide*), was born at Barcelona towards the close of the fourteenth century, professed philosophy, theology, and medicine, from 1430 to 1432, in the university of Toulouse, where he died in 1432. Dr C. L. Kleiber, who has recently examined the oldest MS. relating to Raymond at Paris, conjectures that it is Sabaedo in Spain that must be meant by the place so variously spelt in the different accounts given of him. There are a number of works ascribed to him; but the only one known in our day is the *Theologia Naturalis sive liber creaturarum*, written, according to some, in Spanish, but translated into French by Montaigne in 1569: into Latin at different times—Deventer, 1487; Strasburg, 1496; Nürnberg, 1502; Paris, 1509; Venice, 1581; Lyon, 1648. The author, who was the first to use the expression *Theologia Naturalis*, spent upwards of thirty years in the composition of this work. It was began in 1404, and finished 1436. (See *De Raimundi quem vocant Raymond Sabunde vita et scriptis*, by Dr C. L. Kleiber, 1856.)

RAYNAL, Guillaume Thomas François, better known as the *Abbé Raynal*, was born in the year 1711, and having received his education from the Jesuits, became one of their number. Amongst them Raynal acquired a taste for literature and science; but he was afterwards expelled on account of his impiety. Soon after this event he justified his expulsion by associating with Voltaire, D'Alembert, and Diderot, who employed him to furnish the articles on theology for the *Encyclopédie;* but having no relish, and probably as little qualification, for such work, he devolved it on the Abbé Yvon, whom Barruel allows to have been an inoffensive and upright man. The first work of Raynal is his *Political and Philosophical History of the European Settlements in the East and West Indies.* The style of this work is rambling but animated; it contains many just reflections both of a political and philosophical nature, intermixed, however, with much vague and declamatory speculation. It has been translated into every European language. This performance was followed by a small tract in the year 1780, entitled the *Revolution of America*, in which he pleaded the cause of the colonists with much zeal, censured the conduct of the British government, and discovered some acquaintance with the principles of the different factions; circumstances which induced a belief that he had been furnished with materials by those who knew the merits of the dispute much better than any foreigner could reasonably be supposed to do. The French government instituted a prosecution against him on account of his History of the East and West Indies; but with so little severity was it conducted, that sufficient time was allowed him to retire to the dominions of his Prussian majesty, by whom he was protected, notwithstanding he had treated the character of that sovereign with very little ceremony. At one period the British House of Commons showed him a very singular mark of respect. The speaker having been informed that Raynal was a spectator in the gallery, public business was instantly suspended, and the stranger was conducted to a more honourable situation. But when a friend of Dr Johnson's asked him, "Will you give me leave, doctor, to introduce to you the Abbé Raynal?" the stanch Tory turned on his heel, and said, "No, sir." A love of liberty was the principal trait in Raynal's character. In the month of May 1791 he addressed to the Constituent Assembly an eloquent and impressive letter, in which he proved that it was not the business of the assembly to abolish every ancient institution; that the genius of the French people is such that they never can be happy or prosperous except under a well-regulated monarchical government; and that, if they wished not the nation to fall under the worst kind of despotism, they would increase the power of the king.

Besides the works already mentioned, he was the author of a *Histoire du Staadthouderat*, Paris, 1784; *Histoire du Parlement d'Angleterre de Catherine d'Arragon*, 2 vols., 1750; *Histoire du Divorce Henri VIII.*, 1763; *Anecdotes littéraires, historiques, militaires, et politiques*, 3 vols., 1753. He was deprived of all his property during the Revolution, and died in poverty in the month of March 1796, in the eighty-fourth year of his age.

RAZZI, Giovanni Antonio, surnamed *Il Sodoma*, an eminent Italian painter, was born at Vercelli in Piedmont about 1474. He first became notable at Sieña as an artist of very eccentric conduct. Much of his attention was directed to horse-racing and other frivolous amusements. His house was turned into a menagerie for all sorts of animals. He prided himself in his whimsicalities, and gloried in the nickname of *mattaccio* (buffoon.) He even could not refrain from leaving traces of levity in some of his serious paintings. Yet Razzi had a fine genius, which in his calmer and more collected moods rose to some of the highest excellences in art. Speaking of some of his select works at Sieña, Annibale Caracci declared that "few such works were to be seen." There were "The Epiphany" in the church of S. Agostino, rivalling the style of Leonardo da Vinci; "The Scourging of Christ," in the cloister of S. Francesco, noted for the surpassing excellence of its figures; and "The Swoon of St Catherine of Sieña," in a chapel of S. Domenica, enthusiastically admired by Peruzzi. Razzi died in the great hospital at Sieña in 1554.

READING, a market-town, parliamentary and municipal borough of England, capital of Berkshire, on the Kennet, just above its confluence with the Thames, 36 miles W. by S. of London. It is irregularly built, but has been recently very much improved. The greater part of the town lies in the parish of St Lawrence, on the angle of land formed by the Kennet and Thames, and the principal business streets are in this quarter. To the west lies the parish of St Mary, occupied by many of the poorer people; and to the south that of St Giles, containing most of the best and newest streets. The houses are for the most part substantial, many of them handsome, and the streets broad and well paved. The church of St Lawrence is an edifice mostly in the later English style; but has some portions in the Norman style, in which it was originally built. In 1434 it seems to have been considerably repaired and altered. The tower at the west end is of chequered flint work, and has a peal of ten bells. A similar but not so handsome tower belongs to St Mary's church, which was built in 1550 out of the remains of a more ancient abbey. Besides the church of St Giles, two district churches, and a chapel of ease, there are Independent, Methodist, Quaker, and Roman Catholic churches in the town. The town-hall is a commodious modern structure, having in the lower part accommodation for the grammar school. The county jail and house of correction, after the model of that of Pentonville, occupies a costly edifice of a castellated form. A building, known by the name of the Oracle, for the employment of the poor in ribbon and silk weaving, erected in the seventeenth century by John Kendrick, exhibits a combination of the Grecian and Gothic architecture. Reading has also various almshouses, a dispensary, and an eye-infirmary. The educational establishments include a free grammar school, founded in 1556, and containing in 1851 thirty-five scholars; a blue-coat school, for forty boys; a green-coat school, for twenty-one girls; national, British, and infant schools, &c. A fine public hall affords accommodation to the literary society and mechanics' institute of Reading. For public amusement and recreation there is a theatre, a news-room, and baths. The town was formerly remarkable for its extensive manufactures of woollen goods. This branch of employment has, however, been abandoned, although there is still some industry in various other departments. Silk, ribbons, coarse linen, and sail-cloth are made; and there are also iron foundries, breweries, large building-yards, and establishments for making biscuits. The trade is considerable, and is facilitated by various means of communication with different parts of the country. The Kennet is navigable up to the town for vessels of 120 tons; the Kennet and Avon Canal opens up an intercourse with the large seaports, and the Great Western Railway passes close to the town, and has a station here. Corn, flour, hops, timber, seeds, wool, cheese, and beer are among the articles of trade. Markets are held on Wednesdays and Saturdays, and there are four yearly fairs. The borough is governed by a mayor, five other aldermen, and eighteen councillors; and it returns two members to the House of Commons. Assizes, quarter-sessions, and a county court are held here. The earliest historical notice of the place informs us that in 871 it was in the possession of the Danes, who, after resisting an assault of the West Saxons, were in the following year obliged to evacuate it. In 1006 they again made their appearance, and burned the town. During the civil war between Stephen and Maud, Reading and its castle were of some importance; but the castle seems to have been destroyed not long after. Several of the subsequent monarchs resided and held Parliaments in the town. In the civil war of the seventeenth century Reading was at different times in the possession of both parties, and suffered much during that contest. Among the celebrated men who have been natives of Reading are Archbishop Laud and Sir John Soane. Pop. (1851) 21,456.

Reading, a city in the United States of North America, capital of Berks county, Pennsylvania, on the left or east bank of the Schuylkill River, here crossed by two bridges, 52 miles E. from Harrisburg, and about the same distance N.W. from Philadelphia. It is a handsome town, compactly built, and intersected by straight, clean streets, crossing each other at right angles. It stands on a plain rising gradually from the river, and is inclosed on the east by an eminence called Penn's Mount. Among the most conspicuous public buildings are the court-house; the German Lutheran church, surmounted by a handsome steeple about 200 feet in height; and the German Reformed church, which has also a steeple 150 feet high. In addition to these, it has about twelve churches, an academy, two market houses, two banks, and several public libraries. Reading is a flourishing town, and carries on an active trade, being in point of population and manufactures the third in the state. It is connected with Philadelphia, Pottsville, and other places by railway, and is the centre of a rich and populous agricultural district. It is also largely engaged in the manufacture of iron, hats, shoes, and other articles. It was laid out by William and Richard Penn in 1748; incorporated as a borough in 1783, and as a city in 1847. Pop. (1840) 8410; (1850) 15,743; (1853) about 17,000.

REAL (*realis*), though always importing the existing, is used in various significations and oppositions:—1. As denoting the *thing* as contradistinguished from its *name*. 2. As expressing a *something* in contrast to a *nothing*. 3. As denoting *material* or external, in contrast to *spiritual* or internal. 4. As synonymous with *actual*, and thus as opposed either to the potential or to the possible. 5. As denoting *absolute* or irrespective, in opposition to *relative* or phenomenal existence. 6. As indicating existence as a *subsistence in nature*, as contradistinguished from existence taken as a *representation in thought*. 7. And lastly, a thing which *really* or in itself is one and indivisible, may nevertheless be *logically* and by the mind considered as diverse and plural, and *vice versa*. (For further illustration of the meaning of this word, see Hamilton's edition of Reid's *Works*, note B, p. 805.)

REAL, a Spanish coin of two sorts,—first, the *real of plate*, value about 4¾d.; and the *real of vellon*, worth about 2½d.

REALEJO, a seaport of Nicaragua, on a bay of the Pacific, 28 miles W.N.W. of Leon. The harbour is very good, and is sheltered by an island having two entrances. Safe anchorage is afforded for as many as 200 ships of the largest size. Mahogany and other timber, sugar, cotton, indigo, &c., are exported from the town. Pop. 5000.

REALISM. See Nominalism and Realism.

REASON (Gr. λόγος, Lat. *ratio*, Fr. *raison*, Ger. *vernunft*), is a word of very various signification. Passing by its employment in most languages for cause, motive, argument, principle of probation, or middle term of a syllogism, it is found employed by various philosophers, and often to a greater or less extent by the same philosopher, in the following *five* significations:—1. It has been used both in ancient and modern times to denote our intelligent nature generally. In this sense of the word it comprehends,—(*a.*) Conception, or simple apprehension (ἔννοια, νόησις τῶν ἀδιαιρέτων, *conceptus, conceptio, apprehensio simplex, das Begriefen*); (*b.*) Judgment (ἀπόφανις, *judicium*); (*c.*) Reasoning, or the Discursive faculty (διάνοια, λόγος, λογισμὸς, το συλλογίζεσθαι, *discursus, ratiocinatio*); (*d.*) Intellect, or intelligence proper, either as the intuition or as the place of principles (νοῦς, *intellectus, intelligentia, mens*). 2. In close connection with the preceding signification, from which perhaps it ought not to be separated, is that meaning in which it is used to characterize the legitimate employment of our faculties in general. 3. It has been employed to denote the third and fourth of the above-mentioned functions,—viz., the dianoetic and the noetic. 4. It has been very generally used for the third of the above special functions, reason and reasoning being thus confounded. 5. It signifies the noetic in contrast to the dianoetic faculties, and especially with Kant and his school, who divide reason (*vernunft*) exclusively and emphatically from understanding (*verstand*). This abusive use of the word, for the faculty of the unconditioned, determined its adoption in the philosophy of Fichte, Schelling, and Hegel. (See note A by Sir William Hamilton, in his edition of Dr Reid's *Works;* also the article METAPHYSICS.)

REATE (*Rieti*), an ancient city of the Sabines, was situated on the Velinus (*Velino*), about 48 miles from Rome. Its political importance was small. Although admitted to the Roman franchise along with the neighbouring towns in 290 B.C., it did not enjoy in the time of Cicero any higher privileges than those of a *præfectura*. The chief importance of Reate was derived from its connection with the Velinus. That river moved in a broad and placid stream through the level district on the N.W. side of the city. Its waters rested at intervals in a series of picturesque lakes, which they had formed for themselves along their course. Its ample flood plentifully moistened the soil, and created in the neighbouring meadows the fresh and blooming luxuriance of a garden. So charming, indeed, was the entire scene, that the valley was called by Cicero the *Reatine Tempe*, and the meads were commonly known by the name of the *Rosei Campi*. But this same river was also the cause of public calamity and strife. Its waters held in solution a large quantity of carbonate of lime, which settled down upon the bed in the shape of travertin. When this deposit was allowed to accumulate it checked the current, and the district of Reate was inundated. When it was cleared away the stream became too rapid, and, rushing over a precipice (the *Falls of Terni*) into the Nar, swelled that river until the fields of the neighbouring town of Interamna (*Terni*) were overflowed. Thus a dispute arose between the inhabitants of the two cities, which continued at intervals for many centuries. Cicero, as the patron of Reate, was one of the first who took part in it; and it did not end until in 1785 the evil was rectified by making the Velino join the Nar at an oblique angle.

REAUMUR, RENÉ ANTOINE FERCHAULT, *Sieur de*, distinguished for his laborious researches in natural science, was born at Rochelle, of a good family, in 1683. After having finished his early education in the place of his birth, he studied philosophy at Poictiers, and civil law at Bourges; but he soon relinquished the latter to apply himself to mathematics, physics, and natural history. Having come to Paris, he was received into the Academy of Sciences in 1708. From that hour he was wholly employed in natural history, to which his inclination particularly led him; and his inquiries were not confined to any one department of the subject. His memoirs, observations, and discoveries on the formation of shells, spiders, muscles, the marine flea, the berry which affords the purple dye, and on the numbing power of the torpedo, excited the curiosity of the public, and early announced him as an able, curious, and entertaining naturalist. The French were indebted to him for the discovery of the turquoise mines in Languedoc. He also found out a substance, now used to give false stones a colour, which is obtained from a certain fish called in the French *able* or *ablete*, on account of its whiteness, and which is the *bleak* or *blay* of our writers. His experiments on the art of turning iron into steel, not previously known in France, obtained him a pension of 12,000 livres; and this reward was to be continued to the Academy to support the expense which might accrue in this art. His work on that subject, which first brought him into general notice, was entitled *L'Art de Convertir le Fer Forgé en Acier, et l'Art d'Adoucir le Fer Fondú*, 4to, 1722. He continued his inquiries on the art of making tin and porcelain, and endeavoured to perfect the thermometers then in use. He composed a *Histoire des Rivières Aurifères de France*, and made curious and important observations on the nature of flints, on fossil shells (whence is obtained in Touraine an excellent manure for land), and likewise on birds and insects. He adopted the method for preserving eggs practised from time immemorial in Greece and the islands of the Archipelago, which is to steep or immerse them in oil or melted fat. Another experiment, still more important, made by Reaumur, was the introduction into France of the art of hatching fowls and birds, as practised in Egypt, without covering the eggs. The climate of France proved too severe, however, for carrying out this experiment with entire success. Active, sedulous, and attentive, he was early in his study, often at six in the morning. Exact in his experiments and observations, he let no circumstance escape him. In society he was distinguished through life for his modest and agreeable behaviour. His probity, benevolence, and goodness of heart endeared him to his countrymen. He died in the seventy-fifth year of his age, on the 18th of October 1757. His death was the consequence of a fall, which happened at the castle of Barnardière on the Maine, where he went to pass his vacation. He bequeathed to the Academy of Sciences his manuscripts and all his natural productions. His works consist of a very great number of memoirs and observations on different parts of natural history, printed in the collections of the Academy of Sciences; and a large work, printed separately in 6 vols. 4to, entitled *Memoirs pour servir à l'Histoire des Insectes*, 1734–42. (See Life of Reaumur by Cuvier, in the *Biographie Universelle.*)

REBEC, a three-stringed instrument, tuned in fifths, and played with a bow, similar to the violin. It was introduced by the Moors into Spain, where it seems to have been much used on festive occasions. Milton represents, in his *L'Allegro*, youth and maid dancing to "the jocund *rebeck's* sound;" and Byron, speaking of Seville, says that here "love's *rebec* sounds."

REBUS, an enigmatical representation of some name or thing, by using figures or pictures instead of words or parts of words. Camden mentions an instance of this kind of wit in a gallant who expressed his love to a woman named Rose Hill, by painting in the border of his gown a rose, a hill, an eye, a loaf, and a well; which, in the style of the rebus, reads "Rose Hill I love well." This kind of wit was long practised by the great, who took the pains to find devices for their names. It was, however, happily ridiculed by Ben Jonson in the humorous description of Abel Drugger's device in the *Alchemist*, by the *Spectator* in the device of Jack of Newberry. The origin of the word is ascribed to the priests of Picardy, who have an annual practice of satirizing their neighbours in ingenious squibs called "De *rebus* quæ geruntur." *Rebus*, in heraldry, is a coat of arms which bears an allusion to the name of the person; as three castles for Castleton, three cups for Butler, three conies for Coningsby; a kind of bearings which are of great antiquity.

RECANATI, a town of the Papal States, in the province of Macerata, on the Musone, near the Adriatic, 4 miles S.W. of Loretto, and 9 N.E. of Macerata. A small old town, it stands on a steep height, looking towards the distant Apennines, over an expanse of grassy meadows and rich corn-fields, with clumps of mulberry-trees, and winding streams. There are a cathedral and two other churches here, partially of Gothic architecture; several splendid palaces, and some convents. In the vicinity is a fine aqueduct, stretching from hill to hill over the country between Recanati and Loretto. Pop. 16,000.

RECITATIVO, or Recitative, in music, a kind of singing that differs but little from ordinary pronunciation; such as that in which the several parts of the liturgy are rehearsed in cathedrals, or that in which actors deliver themselves at the opera.

RECKONING. See Navigation, book i., c. x.

RECORDE, Robert, a physician and eminent mathematician, was descended of a respectable family at Tenby in Wales, and lived in the time of Henry VIII., Edward VI., and Mary of England. The time of his birth is not exactly known, but it must have been about the beginning of the sixteenth century; for he was entered of the university of Oxford about 1525, and was elected fellow of All-Souls College in 1531. As he made physic his profession, he went to Cambridge, where he was honoured with the degree of doctor in that faculty in 1545, and was very much esteemed for his extensive knowledge of many of the arts and sciences. He afterwards returned to Oxford, where he publicly taught arithmetic and mathematics, as he had done prior to his going to Cambridge. It appears that he afterwards went to London, and acted as physician to Edward VI. and to Queen Mary, to whom some of his books are dedicated. He wrote, the year he went to the capital, the *Urinal of Physic*, which passed through several editions. He died in the King's Bench prison, Southwark, where he was confined for debt in the year 1558.

He published several works upon mathematical subjects, chiefly in the form of dialogue between master and scholar. Of these the following is a list, viz.:—*The Pathway to Knowledge, containing the first principles of geometry, as they may moste aptly be applied unto practice, bothe for the use of Instrumentes Geometricall and Astronomicall, and also for projection of Plattes, much necessary for all sortes of men*, London, 1551, 4to; *The Ground of Arts, teaching the perfect worke and practice of Arithmeticke, both in whole numbers and fractions, after a more easie and exact forme then in former time hath been set furth*, 1552, 8vo; *The Castle of Knowledge, containing the Explication of the Sphere both Celestiall and Materiall, and divers other things incident thereto, with sundry pleasaunt proofes and certaine newe demonstrations not written before in any vulgare woorkes*, London, 1556, folio; *The Whetstone of Witte, which is the second part of Arithmetike, containing the extraction of rootes, the Cossike practice, with the rules of equation, and the woorkes of surde numbers*, London, 1557, 4to. Wood says that he was the author of several pieces on physic, anatomy, politics, and divinity; but they do not seem ever to have been published. Sherburne states that he also published *Cosmographiæ Isagoge;* that he wrote a book, *De Arte faciendi Horologium*, and another *De usu Globorum, et de statu Temporum*. Professor de Morgan says of him, in *The Companion to the British Almanac for* 1837, in his "Notices of English Mathematical and Astronomical Writers between the Norman Conquest and the year 1600," that he is a "man whose memory deserves a much larger portion of fame than it has met with, on several accounts."

RECORDER, is a person appointed by Her Majesty, by warrant under the sign-manual, as the chief judicial officer of a borough or city having a court of quarter-sessions. His salary is fixed by the council of the borough, and he holds his office during good behaviour. He is placed next in rank to the mayor, and is the sole judge of the court of quarter-sessions, and where there is such, of any court of record for the trial of civil actions. The mayor and recorder are respectively, *ex officio*, justices of the peace within the borough. The recorders were formerly chosen by the corporations.

RECORDS, Public, in the legal sense of the term, are contemporary statements of the proceedings in those courts of law which are courts of record, written upon rolls of parchment. In a popular sense, the name is given to all public documents preserved in a recognised repositary. There is no country in the world so rich as ours in stores of public records, in all branches of its government, whether constitutional, judicial, parliamentary, or fiscal. During the last sixty years upwards of a million of pounds sterling has been expended by the appointment of successive commissioners and parliamentary committees of inquiry on these records; and an act of Parliament was passed (1 and 2 Vict., c. 94), whereby a special agency was constituted for their proper custody. The agency thus specially appointed was the Master of the Rolls. The records of our earlier history are kept on rolls written on skins of parchment and vellum, from nine to fourteen inches wide, and about three feet in length. Sometimes these are attached together, bookwise, by the tops; sometimes they are sewed together consecutively. The earliest record written on paper is during the reign of Edward II. These documents are recorded in Norman-French, Latin, and English, which became the prevailing language of records in the reign of the second George. The public records are now being methodized, regulated, digested, and bound, besides being calendared and indexed. The task is a gigantic one; and if one may judge from a single specimen,—the Court of Common Pleas,—some 1200 miles of parchment, 9 inches wide, will require patiently to be read through, before any one can consult these important records with any degree of facility. By a recent regulation of the Master of the Rolls, literary inquirers are permitted to search for and make notes of records gratis, provided they can satisfy the deputy-keeper that their application is for a *bona fide* literary purpose. Besides the offices for modern records attached to each court, there are the following repositories in which different branches of the public records are to be found:—

The Tower, Thames Street; Chapter-House, Westminster Abbey; Rolls Chapel, Chancery Lane; Duchy of Lancaster, Lancaster Place, Strand; Duchy of Cornwall, Somerset House; Common Pleas, Carlton Ride and Whitehall Yard; Queen's Remembrancer's Records in Carlton Ride and Tower of Westminster Hall; Augmentation Office, Palace-Yard, Westminster; Pipe Office, Somerset House; Lord Treasurer's Remembrancer, Somerset House; Land Revenue, Carlton Ride; Pell-Office, 1 Whitehall Yard; Exchequer Pleas, 3 Whitehall Yard; First-Fruits Office, Temple.

The best works of general reference as to the subjects of the public records is the *Report of the Select Committee of* 1800.

RECTOR. See Parson.

RECURRING SERIES. See Algebra.

RECUSANTS, the name applied to those who refused to attend divine service on Sundays or holidays, according to the forms of the church established in England. The use of the term in temporal courts can be traced back as far as 1 Elizabeth, c. 2. The statutes against recusancy were fourfold: 1. Those who absented themselves from the church from indifference, irreligion, or dissent, were termed "recusants" simply; 2. After conviction, such persons were styled "recusants-convict;" 3. Those professing the Roman Catholic faith received the name of "Popish recusants;" and 4. Those who had been convicted of Popery in a law court were termed "Popish recusants-convict." Protestant dissenters were relieved from the penalties instituted against recusancy at the Revolution by the Toleration Act, 1 Will. and Mary, c. 18. The exemption in this act in favour of those denying the doctrine of the Trinity, was repealed in 1813 by 53 Geo. III., c. 160; and Roman Catholics were exempted from prosecution in 1791 and 1729, on the ground of their peculiar faith. The statutes against recusants, who not being Roman Catholics or Protestant dissenters, are still in force, though seldom insisted on.

RED. See CHROMATICS.

REDDITCH, a town of England, county of Worcester, on a hill near the borders of Warwickshire, 12 miles S.S.W. of Birmingham. It is a well-built, straggling place, containing places of worship belonging to the Established Church, the Methodists, Independents, and Roman Catholics; national schools, a literary and scientific institution, &c. Needles, fish-hooks, and similar articles are made in large quantities. There are, too, breweries, malt-houses, and brick-kilns. Pop. 4802.

REDEMPTION. See THEOLOGY.

REDON, a town of France, capital of an arrondissement in the department of Ille-et-Vilaine, at the foot of a hill on the Vilaine, 39 miles S.S.W. of Rennes. It is well built, and contains a fine Gothic church, formerly attached to an abbey, with a much-admired apse. The abbey buildings are now occupied by a college. Redon is favourably situated for commerce, as the Vilaine is navigable, and the two branches of the canal between Nantes and Brest unite here. Ship-building and the making of serge are carried on here; and there are large slate quarries in the vicinity. The chief articles of trade are,—colonial produce, slates, iron, lead, timber, pitch, tar, wine, brandy, butter, salt, hemp, flax, sail-cloth, leather, &c. Pop. (1856) 4847.

REDOUBT. See FORTIFICATION.

RED RIVER, one of the affluents of the Mississippi, from the west, is formed by the union of the Salt Fork and South Fork in Texas, about N. Lat. 34. and W. Long. 100. It flows at first eastward, separating between Texas and the Indian territory, till it enters the state of Arkansas. At the village of Fulton, in this state, it bends to the south, passes into Louisiana, and traverses that state in a S.E. direction, joining the Mississippi about 200 miles above New Orleans. Its whole length is estimated at 1200 miles, about 500 of which are regularly navigated by steamers. The name is characteristic; for the water is tinged with red, from the soil of the prairies through which it flows. About 530 miles above its confluence with the Mississippi the river is obstructed by what is called "the Great Raft." This is a vast accumulation of trees and drift-wood, conveyed down the stream and lodged here; so that the river, obstructed in its course, flows over the adjacent country, and forms many side channels and lakes. The impediment was cleared away by the government at great expense in 1834–5, but since that time it has again been formed.

REDRUTH, a market-town of England, county of Cornwall, on the brow of a hill, 8 miles W.S.W. of Truro, and 9 N.W. of Falmouth. The surrounding country, barren and covered with heaps of rubbish, presents no very delightful appearance to the eye, but is full of mineral riches, especially copper and tin. In the town, consisting mainly of one long street, are a town-hall, court-house, market-house, and fine granite clock-tower. The church, about half a mile off, was, with the exception of its Gothic tower, rebuilt in 1768. A chapel of ease in the pointed style, and places of worship for Baptists and Methodists, are among the ecclesiastical edifices of the place. National schools, a grammar school, a literary institution, reading-room, and small theatre, provide for the instruction and amusement of the inhabitants, who are chiefly employed in mining operations and iron-foundries. There is some trade in minerals; and railways connect the town with several seaports. Redruth is said by some antiquaries to be one of the oldest places in the kingdom; but this opinion has been called in question. Pop. (1851) 7095.

RED SEA, an extensive inland sea separating Arabia in Asia, from Abyssinia, Nubia, and Egypt, in Africa. It extends in a north north-westerly direction from the Straits of Bab-el-Mandeb, which connect it with the Indian Ocean, till it terminates in the two gulfs of Suez and Akaba, which inclose between them the mountain region of Sinai.

The name Red by which this sea is known in the present day is simply a translation of *Rubrum*, *Erythræum*, or 'Ερυθρὰ, terms by which it is designated in the works of the ancient classics. This last term, however, as used by Herodotus and some other writers, includes likewise the Persian Gulf and Indian Ocean; and when the Red Sea only is meant, the term *Arabicus Sinus* ('Αράβιος or 'Αραβικὸς κολπος) is used. How the name Red came to be applied to it is a question which neither ancients nor moderns have been able satisfactorily to solve. By some it is held to arise from the red and purple hues of the coral with which this sea abounds, or from the red colour which is occasionally imparted to it by numerous animalculæ floating near the surface; by others from the adjacent country of Edom, which, in the Phœnician and Hebrew tongues, means *red*; while Strabo, Pliny, Curtius, &c., consider it to be derived from a great king named Erythrus, who reigned over that country. It is not improbable that the name, as originally bestowed, was derived from that of the king or the country, and that, when afterwards adopted by the Greeks and Romans, they, mistaking a proper for a descriptive name, translated instead of adopting it. The Hebrew name, *Yam Suph* ("Weedy Sea"), which is also its Egyptian name, is supposed to be derived from the plant-like corals with which it abounds.

This sea lies between Lat. 12. 30. and 30. 2. N., and Long. 32. 38. and 43. 40. E., and has a length of above 1280 miles from the Straits of Bab-el-Mandeb to the town of Suez. Its greatest breadth is 192 miles, under the parallel of 17. N.,—that is, one-third up the sea, whence it narrows pretty uniformly towards both extremities, being 72 miles across at Ras-Mahommed, where it divides to form the gulfs of Suez and Akaba, and nearly of similar breadth at Gibbel Zugar, under the 14th parallel. Its entire circuit, measured round both gulfs, is about 4020 miles, its area 108,154 square miles, and its contents probably about 800,000 cubic miles. The Gulf of Suez, the longer and more western arm of this sea, has a length of 167 miles, and an average breadth of about 20. Its extreme breadth is under 30, and at its mouth it has a breadth of about 17 miles. Its depth, where greatest, is about 50 fathoms, and averages about 22. The port of Suez, from which it takes its name, is situated at the head of the gulf. (See SUEZ.) The area is estimated at 2000 square miles. The Gulf of Akaba, extending in a N.N.E. direction, has an area o[illegible] only about 800 square miles. It is 100 miles in length, 16 miles in breadth where widest, and 7 at the mouth. Its depth for two-thirds of its length is about 120 fathoms, and at one place a depth of 200 fathoms was reached without bottom. The mean depth is probably not less than 70 fathoms.

The Red Sea itself may be said to have generall[illegible] depth of more than 100 fathoms, and in one place 10[illegible] fathoms were sounded without finding bottom. A reef [illegible] shallow, running across from Mocha, in Lat. 13. 30., has been carefully sounded, and has an average depth of from 25 to 30 fathoms, its greatest depth being 40, near mid-channel. From this it again deepens to upwards of 125 fathoms as it approaches the straits. The entrance to the sea is divided by the small island of Perim into two channels, called the Great and Little Straits: the former, between the island and the coast of Africa, being 13 miles broad; the latter, between the island and Cape Bab-el-Mandeb, 1¾ miles. The Great Strait has an average depth of about 80 fathoms, and for a breadth of 6 miles in mid-channel it exceeds 100

The Little Strait has a depth of from 12 to 17 fathoms, and is the one that is almost always preferred by vessels entering the sea, having a fine sandy bottom and a depth of 30 feet of water up to both shores. The island of Perim has recently been taken possession of by the English. (See Perim.)

The islands of the Red Sea are numerous, but they are mostly all of small size, and occur chiefly along the shores. Off the western coast, not far from Massuah, is a numerous group called the Dhalak Archipelago, and not far from the opposite coast is a group called the Farsan Islands. South of these groups are several other islands, one of which, Gibel-Teer, in Lat. 15. 30., has an active volcano rising about 900 feet above the sea. A violent eruption took place in one of the Zugar islands, in Lat. 15., in 1846. Indeed, all the islands in the middle of the sea between 12. and 16. N. Lat. are volcanic. Coral reefs and islands are also numerous in this sea, and are very detrimental to navigation. The reefs most commonly extend in long strips parallel to, and generally about a quarter of a mile from, the shore. Their outer side rises from deep water; and their summits are seldom more than 4 or 5 feet from the surface. They are frequently united with the adjacent continent, so as to render the shores almost inaccessible; but in other cases the side towards the mainland has a gentle slope downwards, forming a channel of sufficient depth to admit of being navigated by small vessels. The Red Sea is the most northern portion of the ocean where coral reefs occur, and they are more numerous here than in any other part of equal extent.

From the position of the Red Sea, in a deep valley between the elevated table-land of Arabia on the E., and the high lands of Abyssinia, Nubia, and Egypt, on the W., the prevailing winds are in the direction of its length, either S.S.E. or N.N.W. The former commences in October and continues till May or June, blowing with considerable strength in February, but diminishing gradually as summer sets in, and occasionally ceasing almost altogether. In the lower part of the sea, being confined within comparatively narrow limits, it blows with considerable violence, and is stronger towards the Arabian than the Abyssinian shore; but it slackens as it passes the Harnish and Zugar islands, under the 14th parallel, where the sea begins to expand, and by the time that it gets as high as Jiddah, Lat. 21. 30., it is for the most part light and variable. From December to April southerly winds are occasionally experienced in the Gulf of Suez, sometimes freshening into a gale, and blowing for several days. The winds, however, from Suez to Jiddah are mostly northerly throughout the year, and occasionally blow with considerable violence. The N.N.W. winds prevail in the lower half of the Red Sea from June to October, blowing with considerable violence in June and July, and becoming light and variable in August and September. As the time of their extinction approaches, there are sometimes calms of several days, when the sea breezes become excessive. In those parts where, or at the times when, the regular winds are little felt, land and sea breezes prevail, particularly on the coast of Arabia. The fine season is usually from August to October; and showers, such as they are, are chiefly experienced from November to March.

The direction of the wind has a considerable effect in raising or lowering the surface of the sea, especially in the northern parts. Near Suez the direction of the wind makes a difference of about 4 feet in the depth of water. Little is yet known of the tides of the Red Sea: at Suez they are said to rise 5 feet at neap and 7 at spring tides; but of course this must depend very much upon the wind. It was long supposed that the Red Sea must be much salter than the general ocean, being situated in an almost rainless and riverless district, while the evaporation was very considerable. This, however, is found not to be the case; and hence it is supposed that there is a constant under-current of the denser and salter water through the straits to the Indian Ocean. The evaporation is estimated at about 8 feet annually over the entire surface; whereas the quantity of rain falling in the course of a year cannot exceed an inch. According to the measurements of the French engineers in 1799, the Red Sea at Suez was said to be 30 feet higher than the Mediterranean; but recent measurements have shown this to be a mistake, and that the height is only about 3 feet. Indeed, there is every reason to believe that the Red Sea at one time communicated with the Mediterranean. The distance between the two is only about 90 miles, and all the intervening space is of recent deposit, a considerable portion of it being still below the level of the two seas. It is proposed to construct a canal connecting the two seas, and thus materially to shorten our communication with the East. (See Suez.)

Round its entire circuit the Red Sea is walled in by immense masses of mountain, which, down to Jiddah, in Lat. 21. 30., approach close to the shore. On the African side, down to the 16th parallel, isolated hills alone skirt its borders, the higher ranges being 40 or 50 miles off; while on the opposite shore, between the same parallels, the land rises gently towards the interior of Arabia. Between the 16th and 12th parallels a range of volcanic hills runs nearly parallel to, and at the distance of above 14 miles from, the shore on the African side, and there is a similar range of greater magnitude and of the same character on the Arabian coast. The other rocks consist chiefly of nummulite limestone, forming part of that vast band which stretches from the Alps to the Himalayas. The immediate shore consists of a belt of sand and gravel sloping upwards from high-water mark to a distance varying from some hundred yards to many miles. It abounds with shells and corals identical with those in the sea itself, and is obviously an upheaved beach of comparatively modern date.

Within the last few years the commerce and navigation of the Red Sea have very much increased, and it is now regularly navigated by British steamers, as forming part of the overland route to India. During the year 1857 no fewer then 111 English steamers entered and left the port of Suez, having an aggregate burden of 144,500 tons, and 36,600 horse-power. They carried 10,156 passengers, 23,520 cases of letters, and 137,770 packages of merchandise or gold and silver, to the value of L.28,248,670. A considerable communication is kept up between the two shores by pilgrims from the eastern countries of Africa visiting Mecca and Medina. Grain and slaves are also largely transported from Africa to Arabia. The principal harbours on the Arabian side are Mocha, Hodeida, Locheia, and Jiddah; and on the African, besides Suez, Cosseir, Suakim, and Massuah. Mocha, Hodeida, and Locheia are the three ports of Yemen, and export coffee, wax, myrrh, gums, ivory, leather, and grain; receiving in return cotton goods, silks, draperies, iron, copper, lead, tools, tobacco, rice, and sugar. The aggregate value of the exports and imports is estimated at about L.730,000 annually. The first of these, Mocha, is now in a ruinous condition, having probably not more than 2000 inhabitants. The value of its exports does not exceed L.80,000, of which coffee constitutes about a fourth. Hodeida is now the principal place for the export of coffee, amounting in value to about L.200,000 annually, while its other exports amount only to about L.40,000. Locheia exports chiefly grain, the value of which may be about L.40,000 annually. Jiddah carries on a very considerable trade, and being the port of Mecca, it is the resort of numerous pilgrims from all parts. It is built along the shore in the form of a parallelogram, and contains about 4000 houses, with a resident population of about 20,000. Merchants assemble here; and goods are brought from Muscat, India, Singapore, Persia, Syria, Egypt, and Eastern Africa. The exports and imports together exceed a million sterling. The trade of Jiddah is almost entirely in the hands of Indian merchants, who are English subjects. There are very few European houses of commerce; but France and England have each a consul here. In June last (1858) the Mussulman population rose against the Christians, and massacred no less than forty-five of them, including the two consuls. Massuah, the principal *entrepot* of the trade of Abyssinia, stands on a low, sandy, and barren island, separated from the mainland by a channel about a quarter of a mile wide, which serves as its port. Its exports, which are estimated to exceed L.500,000 annually, consists chiefly of coffee, myrrh, incense, hides, gum, ivory, senna, slaves, and gold-dust; and its imports, of cotton and silk stuffs, red and blue cloths, matchlocks, rice, sugar, tea, lead, iron, copper, timber, &c. Cosseir derives its importance from being the granary of the barren Hedjaz. The export of cereals amounts to about L.25,500; and that of hides, tusks, &c., to about L.3000; while the imports are about L.17,500. The exports of Suakim amount to about L.51,000. The principal article is butter, which is consumed in incredible quantities on the Arabian coast. Among the other exports are slaves, salt, coffee, dates, gums, hides, cereals, ivory, gold, cattle, musk, and ostrich feathers. At present (May 1859) an electric telegraph is being laid down in the Red Sea.

The Red Sea is celebrated in sacred history as having been miraculously divided, and a passage opened up through it for the children of Israel in their journey from Egypt. The exact place of this miracle has been the subject of much controversy; but it is now generally agreed that it must have been at one or other of two places,—either in the neighbourhood of Suez, or 18 miles farther south, at the mouth of the Wady Tuârik. Which of these it was, would depend upon the route that they took on leaving Egypt; and if we can fix upon that with any degree of certainty, with the like certainty can we declare that the one or the other was the scene of the miracle. Egypt is connected with the Red Sea by two valleys, along one or other of which the Israelites must have travelled; the one terminating at Suez, the other at Wady Tuârik. The former and more northern of these has its entrance in the province of Esh-Shurkiyeh, near the ruins of the ancient Heroopolis; the latter in the neighbourhood of Cairo. According to Josephus, they must have taken the latter of these routes, for he says that they set out from Latopolis, near Cairo; but against him there is the authority of the Septuagint, which makes the departure to have been from the neighbourhood of Heroopolis. Goshen, too, is now generally agreed to have been in the present province of Esh-Shurkiyeh, which at this day is what Goshen was in ancient times, "the best of the land" of Egypt, and that portion of the country lying nearest to Canaan. The distance by the more southern of these routes is no less than 70 miles; and this of itself is a strong objection to any argument that may be advanced in its favour, as they accomplished the journey in three days, though encumbered with women and children and cattle; whereas the usual day's march of the best appointed armies, either in ancient or modern times, is not estimated higher than 14 English miles. Dr Robinson, after examining this route, says, "We were quite satisfied, from our own observation, that they could not have passed to the Red Sea from any point near Heliopolis or Cairo in three days, the longest interval which the language of the narrative allows. Both the distance and the want of water on all the routes are fatal to such an hypothesis." The distance by the northern route is only about 30 or 35 miles; and this they could have easily accomplished in three days. Some indeed hold that they set out by the northern passage, and afterwards took a road between two ranges of mountains, and thus entered the more southern valley; but in this way the journey would be at least as long as by the longer of the two routes.

We think, however, that a careful study of the recorded narrative itself is sufficient to settle the question as to the route. On the evening of the second day they were "encamped in Etham, in the edge of the wilderness," when God commanded them to "turn and encamp before Pi-hahiroth, between Migdol and the sea over against Baal-zephon." Now, in Numbers (xxxiii. 8) we are told that "they departed from before Pi-hahiroth, and passed through the midst of the sea into the wilderness, and went three days' journey into the wilderness of Etham." This wilderness of Etham must therefore have been on the eastern side of the Red Sea, and Etham itself in all probability was somewhere about the head of the sea. What more natural, then, than to suppose that the children of Israel, on setting out, had received no special directions as to their course, and had thus taken the usual and proper route to Sinai, intending to pass round the head of the sea and along its eastern side. On reaching Etham, however, they were commanded to "turn," and instead of continuing along the eastern side, to come down the western, and to encamp "between Migdol and the sea," God having thus intended to bring about their deliverance from the host of Pharaoh. The object of the miracle was thus not to open up a passage for the Israelites, but to deliver them from the Egyptians.

If we examine the sea itself, its evidence is almost equally strong in favour of the northern passage. At Wady Tuârik it is about 12 miles across, and it is difficult to suppose how a large body, of upwards of two millions, as the Israelites must have been, including women and children, with numerous flocks of cattle, could have passed over here in a single night. The depth also is about 180 or 200 feet; and we cannot suppose that even Pharaoh would have attempted to pass through twelve miles of a defile, with water piled up to that height on each side, especially with the terrible ten plagues still fresh in his memory. At Suez, where a tongue of land projects into the sea, it is only about 1150 yards across, but is of some depth. Above and below this, where it is wider, there are fords. Niebuhr crossed at one of these, above the town, at low tide, when the water only came up to about the knee. There is here, however, undoubted evidence of a gradual filling up going on. "The passage," says Niebuhr, "would have been naturally more difficult for the Israelites some thousands of years back, when the gulf was probably larger, deeper, and more extended towards the north; for, in all appearance, the water has retired, and the ground near this end has been raised by the sands of the neighbouring desert." Dr Robinson's testimony is to the same effect. He says,—"The sand from the northern part of the desert, driven by the strong north-east wind which often prevails, is continually carried towards and into the water; and the process of filling up is still going on." Though it is not improbable that the passage took place here, above Suez, we are rather inclined to think that it was effected at a point below that town. At a short distance below Suez there is at the present day a ford, which is sometimes crossed by the Arabs at low tides, the water being then about five feet deep. Shoals extend to some distance from either shore; but if we suppose, with Dr Robinson, that they crossed in an oblique direction, the distance from bank to bank would be from three to four miles. The depth of water may then have been greater here than it is at present; but even now, at high water, it is from ten to twelve feet. Naturally, if we may so speak, this place was peculiarly well adapted for the miracle. It is exactly the part of the sea most likely to be affected by the wind in the manner described. A strong north-east wind (as Dr Robinson supposes that it was, for in the indefinite phraseology of the Hebrew an east wind means any wind from the eastern quarter), supernaturally directed, might readily be supposed to dry up this ford, by coming down obliquely upon it, and driving away the waters to the south, at the same time that it was keeping back, within the tongue of land at Suez, the waters to the north of it. This, in fact, answers exactly to the account of the miracle as given by Moses; for he says that the "Lord caused the sea to go back by a strong east wind." The wind being thus the immediate agent in the miracle, we are naturally led to look for a place where it could have had some effect in bringing it about; and at no place, as we have seen, could it have acted so efficiently as at the ford below Suez. At Wady Tuârik, on the other hand, the depth is so great that it is impossible to suppose that the wind could have had any effect in dividing the waters; and had the miracle been wrought here, it is likely that Moses would have taken some other mode of describing it than by attributing to the wind what it manifestly could have had no power to bring about; besides, as one writer shrewdly remarks, the waters would not then have been said to form a wall, but a mountain. It is to be remembered too, that the Israelites were crossing from west to east; and how in the course of a single night, encumbered as they were, could they pass over 12 miles in the bottom of the sea with a strong east wind blowing directly against them. Indeed, those who maintain that the passage was effected at Wady Tuârik require the aid of some half-dozen miracles; whereas from Moses' account, we have no reason to infer that there were more than one.

There are some, however, who object to this view, that it reduces the miracle to the smallest possible dimensions; and as they cannot bring forward any arguments to support their opinions, they attempt to strengthen their cause by branding as rationalists and disbelievers all who differ from them. It is to be regretted that this mode of argument has been adopted by even those from whom it was little to be expected, and serves only to indicate the extreme weakness of their cause. A miracle is not the less a miracle because the means by which it is effected may seem small in our eyes. In this case the miracle consisted in the delivering of the children of Israel from the host of the Egyptians. The apparent insignificance of the means only manifests the more strikingly the power of God. If the simplicity and plainness of the sacred Scriptures be an argument for their inspiration, not less do we think is the simplicity of the miracles an argument that they were wrought by God. There were many more striking and signal ways in which He could have destroyed the Egyptians, and delivered the Israelites; but His workings are always simple and unostentatious. He ever chooses the smallest and most easy means for the accomplishment of even the greatest ends. Indeed so much is this the case, that if the claims of the two were otherwise equal, we should unhesitatingly declare in favour of the narrower, shallower, and easier passage. Those who attempt to magnify God's miracles, and fancy that in this way they are doing Him a service, would do well to remember that they are doing what neither He nor the inspired penmen have done before, and may well doubt whether they be not assuming an office which has not His sanction. The days of miracles are now past. God speaks not to us in the great and strong wind, rending the mountains and breaking in pieces the rocks, nor in the earthquake, nor in the fire, but in the still small voice of reason and conscience. It is wrong, then, to attempt to build upon the former that faith which can only have a sure foundation upon the latter.

RE-DUPLICATION of sounds in musical harmony. See the article MUSIC, under section *Harmony*.

REE, LOUGH, a lake of Ireland, formed by an expansion of the Shannon, lying between the counties of Longford and Westmeath on the E., and that of Roscommon on the W.: length, from N. to S., about 15 miles; greatest breadth, 8; area, 42 square miles; extreme depth, 75 feet. Its shores are irregular in outline, but extremely beautiful in scenery; and the few islands which the lake contains also possess many attractions. Besides the Shannon, Lough Ree receives the Inny from the east.

REEFS, CORAL. See PHYSICAL GEOGRAPHY, § 86.

REES, ABRAHAM, a very learned dissenting divine, was born in 1743 at Llanbrynmair in Wales, and studied for the ministry at Hoxton academy. As his mind developed, it became eminently and keenly practical. He was eager to seize and ready to employ any knowledge that might be turned to immediate advantage. There was scarcely an office within the sphere of his profession for which he had not qualified himself, and to which he was not willing to apply all his energies. For a considerable period he was both mathematical tutor at Hoxton academy and pastor of the Presbyterian congregation, St Thomas's, Southwark. His activity only extended itself when, in 1783, he was translated to the congregation of Jewin Street, in the Old Jewry. Every subject that had any reference to the cause of public enlightenment received part of his attention. He kept up his acquaintance with the general learning of the day. He delivered occasional lectures at Salters' Hall in the winter evenings; became a leading business-man among the Nonconformists of the capital; and took an active part in every scheme of philanthropy. His literary labours at the same time were not neglected. Many of his sermons issued at intervals from the press. Several contributions from his pen found their way into the *Monthly Review*. *Chambers's Encyclopædia* appeared under his editorship between 1781 and 1786. At length his own *Cyclopædia* began to be published in 1802, and was completed in forty-five quarto volumes in 1819. In consideration of all these great and multifarious labours, Rees was held in high estimation. At his death in 1825 he was D.D. of the university of Edinburgh, and a member of the Royal Society, and of several other learned bodies.

REETH, a market-town of England, in the North Riding of Yorkshire, on the left bank of the Swale, 53 miles N.W. of York. It contains various dissenting churches and two endowed schools. Lead is obtained in the vicinity. Besides weekly markets, several annual fairs are held here. Pop. (1851) 1344.

REEVE, CLARA, the authoress of *The Old English Baron*, was the daughter of the Rev. William Reeve, rector of Freston and of Kerton in Suffolk, and perpetual curate of St Nicholas, and was born at Ipswich in 1723. Her father was "an old Whig," and from him she learned all that she knew: he was her oracle, and used to make her read the parliamentary debates while he smoked his pipe after supper. Under the same paternal tuition, she also read Rapin's *History of England*, Cato's *Letters*, the Greek and Roman histories, and Plutarch's *Lives*, at an age when few people of either sex can read their own names. She first became an authoress by translating from the original Latin Barclay's fine old romance of Argenis, which was published in 1762, under the title of *The Phœnix*. It was not, however, until 1767 that she produced her *Champion of Virtue*, afterwards called *The Old English Baron*, a work written after the manner of the *Castle of Otranto*, by Horace Walpole. This production is inscribed to Mrs Brigden, the daughter of Richardson, who is stated to have lent some assistance in the revision and correction of the work. The success of *The Old English Baron* encouraged

Miss Reeve to devote more of her leisure hours to literary composition, and accordingly she published in succession *The Two Mentors*, *The Progress of Romance*, *The Exile*, *The School for Widows*, *Plans of Education*, and *Memoirs of Sir Roger de Clarendon*, a natural son of the Black Prince, with *Anecdotes* of many other eminent persons of the fourteenth century. The various novels produced by this lady are all marked by excellent good sense, pure morality, and a considerable command of those qualities requisite to constitute a good romance. They were, generally speaking, favourably received at the time; but none of them took the same strong possession of the public mind as *The Old English Baron*, upon which the fame of the author may be considered as now exclusively rested, and by which alone she will be known to posterity. She died at Ipswich in December 1808, in her seventy-fifth year. (For an estimate of her works, see Romance.)

REFLECTION OF LIGHT. See Optics.

REFORM, Parliamentary. See Parliament.

Reformation begun by Luther.

REFORMATION is, in general, the act of reforming or correcting an error or abuse in religion, discipline, or the like. The word is used, by way of eminence, for that great reformation in the corrupted system of Christianity commenced by Luther in the year 1517. By some it is pretended that the only motive which Luther had in beginning the Reformation was his enmity to the Dominicans, who had excluded his order, the Augustinians, from all share in the gainful traffic of indulgences. But this does not seem at all probable, for such a motive would not naturally lead him to deny the virtue of indulgences, whilst his conduct could not but exclude him for ever from any chance of a share in the traffic, which otherwise he might perhaps have obtained. Besides, this traffic was so contrary to the common principles of reason and honesty, that we cannot wonder at finding one man in the world who had sense enough to discern it, and courage enough to oppose such a disgraceful practice. In all probability, however, the imagined insignificance of the first Reformer was the reason why he was not persecuted and exterminated at the very outset, as others had been before him. Another reason probably was, that he did not at once attack the whole errors of Popery, but brought about his reformation gradually, probably as it occurred to himself.

Zuinglius in Switzerland.

The Reformation commenced in the city of Wittenberg in Saxony, but was not long confined either to that city or to the province in which it is situated. In 1520 the Franciscan friars, who had the care of promulgating indulgences in Switzerland, were opposed by Zuinglius, a man not inferior in understanding and knowledge to Luther himself. He proceeded with the greatest vigour to overturn the whole fabric of Popery; but his opinions were declared to be erroneous by the universities of Cologne and Louvain. Notwithstanding this, the magistrates of Zurich approved of his proceedings; and the whole of that canton, together with those of Berne, Basle, and Schaffhausen, embraced his opinions.

Reformation opposed in Germany.

In Germany, Luther continued to make great advances, without being in the least intimidated by the ecclesiastical censures which were thundered against him from all quarters. Continually protected by the German princes, either from religious or political motives, his adversaries could not accomplish his destruction as they had done that of others. Those princes who were upon bad terms with the court of Rome took advantage of the success of the new doctrines, and in their own dominions easily overturned a church which had lost all respect and veneration amongst the inferior ranks. The court of Rome had disobliged some of the smaller princes in the north of Germany, whom the Pope probably thought too insignificant to be worth managing; and they, in revenge, universally established the Reformation in their own dominions. Melancthon, Carlstadt, and other men of eminence, also greatly forwarded the work of Luther; and in all probability the papal hierarchy would have soon come to an end, in the northern parts of Europe at least, had not the Emperor Charles V. given a severe check to the progress of the Reformation in Germany. In order to follow out the schemes dictated by his ambition, he thought it necessary to ingratiate himself with the Pope; and the most effectual method of doing this seemed to be by the destruction of Luther. The Pope's legates insisted that Luther ought to be condemned by the Diet of Worms as a most notorious, avowed, and incorrigible heretic. This, however, appeared unjust to the members of the Diet, and he was summoned to appear personally, which he accordingly did without hesitation. There is not the least doubt that his appearance there would have been his last in this world, if the astonishing respect that was paid him, and the crowds who came daily to see him, had not deterred his judges from employing summary means against the author of such a heresy. He was therefore permitted to depart with a safe-conduct for a certain time; after which he remained in the state of a proscribed or intercommuned criminal, to whom it was unlawful to perform any of the ordinary offices of humanity.

Form of worship first altered at Wittenberg.

During the confinement of Luther in a castle near Wartburg the Reformation advanced rapidly, almost every city in Saxony embracing the Lutheran opinions. At this time an alteration in the established forms of worship was first adventured upon at Wittenberg, by abolishing the celebration of private masses, and giving the cup as well as the bread to the laity in the Lord's Supper. In a short time, however, the new opinions were condemned by the university of Paris, and a refutation of them was attempted by Henry VIII. of England. But Luther was not to be thus intimidated. He published his animadversions on both with as much acrimony as if he had been refuting the meanest adversary; and a controversy conducted by such illustrious antagonists attracted general attention, the Reformers daily gaining new converts both in France and Germany. (See Luther).

Disputes and divisions.

But whilst the efforts of Luther were thus everywhere crowned with success, the divisions began to prevail which have since so much agitated the Reformed churches. The first dispute occurred between Luther and Zuinglius concerning the manner in which the body and blood of Christ were present in the Eucharist. Luther and his followers, although they had rejected the notion of transubstantiation, were nevertheless of opinion that the body and blood of Christ were really present in the Lord's Supper in a way which they could not pretend to explain. Carlstadt, who was Luther's colleague, first suggested another view of the subject, which was afterwards confirmed and illustrated by Zuinglius, namely, that the body and blood of Christ were not really present in the Eucharist; and that the bread and wine were no more than external symbols to excite the remembrance of Christ's sufferings in the minds of those who received them. Both parties maintained their tenets with the utmost obstinacy, and, by their divisions, first gave their adversaries an argument against them, which to this day the Catholics urge with great force; alleging that the Protestants are so divided that it is impossible to know who is right or who is wrong; and arguing from these divisions, that the whole doctrine is false.

Civil war in Germany.

To these intestine divisions were added the horrors of a civil war, occasioned by oppression on the one hand, and by enthusiasm on the other. In 1525 a great number of seditious fanatics arose on a sudden in different parts of Germany; and having taken arms, they united their forces, and made war against the empire, laying waste the country with fire and sword, and committing everywhere the most barbarous cruelties. The greater part of this furious mob was composed of peasants and vassals, who groaned under heavy burdens, and declared that they were no longer able to bear the despotic government of their chiefs; and hence this sedition received the name of the War of the Peasants. At first this rabble declared that they had no other motives than the redress of their grievances; but no sooner had Munzer the Anabaptist placed himself at their head, than the face of things was entirely changed, and the civil commotions in Saxony and Thuringia rapidly increased. (See the article ANABAPTISTS; also Ranke's *History of the Reformation*, vol. ii., English edition, 1845; and Mrs Sinnett's *Bye-ways of History*, 1847.

Reformation established in Saxony.

In the meantime Frederick, Elector of Saxony, and Luther's great patron, died, and was succeeded by his brother John. Frederick, though he had protected and encouraged Luther, yet was at no pains to introduce the reformed religion into his dominions. But with his successor it proved otherwise; for he, being convinced that Luther's doctrine must soon be totally destroyed and suppressed unless it received a speedy and effectual support, ordered Luther and Melancthon to draw up a body of laws relating to the form of ecclesiastical government, the method of public worship, and other necessary matters, which were to be proclaimed by heralds throughout his dominions. This example was followed by all the princes and states of Germany who had renounced the papal supremacy; and a similar form of worship, discipline, and government was thus introduced into all the churches which had dissented from that of Rome. This open renunciation of the ancient ecclesiastical jurisdiction changed the face of affairs; and the patrons of Popery intimated, in a manner not at all ambiguous, that they intended to make war upon the Lutheran party. On the other hand, the Lutherans, apprised of these hostile intentions, began to deliberate on a proper plan of defence against the attack with which they were threatened.

Resolutions of the Diet of Spires.

The Diet of the empire assembled in the year 1526 at Spires, where the emperor's ambassadors were desired to use their utmost endeavours to suppress all disputes about religion, and to insist upon the rigorous execution of the sentence which had been pronounced against Luther and his followers at Worms. The greater part of the German princes, however, opposed this motion with the utmost resolution, declaring that they could neither execute the sentence, nor come to any determination with regard to the doctrines by which it had been occasioned, before the whole matter had been submitted to the decision of a council lawfully assembled; and further alleging that the decision of controversies of this nature belonged properly to a general council, and to it alone. This opinion, after long and warm debates, was adopted by a majority, and was at length consented to by the whole assembly. It was unanimously agreed to present a solemn address to the emperor, entreating him to assemble a general council without delay; whilst in the meantime it was also agreed that the princes of the empire should, in their respective dominions, be at liberty to manage ecclesiastical affairs in the manner they should think most proper, yet so as to be able to give to God and the emperor a proper account of their administration whenever it should be required of them.

These resolutions proved exceedingly favourable to the cause of reformation. Neither had the emperor for some time any leisure to give disturbance to the Reformed. The war which about this time ensued between him and the Pope gave the greatest advantage to the friends of reform, and considerably augmented their number. Several princes, whom the fear of persecution and punishment had hitherto prevented from lending their assistance, publicly renounced the Catholic religion, and introduced among their subjects the same forms of religious worship, and the same system of doctrine, which had been received in Saxony. Others, though placed in such circumstances as discouraged them from acting in an open manner against the interests of the Roman Pontiff, were, however, far from discovering the smallest opposition to those who withdrew the people from his despotic yoke; nor did they molest the private assemblies of those who had separated themselves from the communion of Rome. And in general all the Germans who, before these resolutions of the Diet of Spires, had rejected the papal discipline and doctrine, were now, in consequence of the liberty they enjoyed, wholly employed in bringing their schemes and plans to a certain degree of consistence, and in adding vigour and firmness to the cause in which they were engaged.

Revoked by the emperor.

But this tranquillity and liberty were not of long duration. In the year 1529 a new Diet was assembled at the same place by the emperor, after he had quieted the troubles in various parts of his dominions, and concluded a peace with the Pope. The power which had been granted to princes, of managing ecclesiastical affairs until the meeting of a general council, was now revoked by a majority of votes; and every change declared unlawful that should be introduced into the doctrine, discipline, or worship of the established religion, before the determination of the approaching council was known. This decree was considered as iniquitous and intolerable by the Elector of Saxony, the Landgrave of Hesse, and other members of the Diet, who were persuaded of the necessity of a reformation. The promise of speedily assembling a general council they looked upon as an artifice of the Church of Rome, conceiving that a free and lawful council would be the last thing to which the Pope would consent.

Origin of the name *Protestants.*

When, therefore, they found that all their arguments and remonstrances made no impression upon Ferdinand, the emperor's brother, who presided in the Diet, Charles himself being then at Barcelona, they entered a solemn protest against this decree on the 19th of April, and appealed to the emperor and a future council. Hence arose the denomination of *Protestants*, which from this period has been given to those who separated from the communion of the Church of Rome. The princes of the empire who entered this protest were, John, Elector of Saxony; George, Elector of Brandenburg; Ernest and Francis, dukes of Lunenberg; the Landgrave Philip of Hesse; and Wolfgang, Prince of Anhalt; and they were seconded by fourteen imperial towns, viz., Strasburg, Ulm, Nuremberg, Constance, Reutlingen, Windsheim, Memmingen, Nordlingen, Lindau, Isny, Kempten, Heilbron, Wissenburg, and St Gall. (See Walch's *Dis. Histor. de Liberis Imperii Civitatibus*, Gött. 1755.)

The dissenting princes, who were, besides, the protectors and heads of the Reformed churches, had no sooner entered their protest, than they sent proper persons to the emperor, who was then upon his passage from Spain to Italy, to acquaint him with their proceedings in this matter. The ministers employed in this commission executed it with the greatest intrepidity and presence of mind; but the emperor, exasperated at the audacity of those who presumed to differ from him, caused the ambassadors to be arrested. The news of this violent step made the Protestant princes conclude that their personal safety and the success of their cause depended entirely upon their own courage and union. They therefore determined to enter into a solemn confederacy; and for this purpose they held several meetings at Rothach, Nuremberg, Smalcald, and other places; but so different were their opinions and views that for a time they could determine upon nothing. (See Salig's *Hist. of the Augs. Confession*, vol. i., book ii., c. i.)

Conference between Luther and Zuinglius.

One great obstacle to the intended confederacy was the dispute which had arisen between Luther and Zuinglius concerning the real presence of Christ in the Lord's Supper. To terminate this dispute if possible, Philip, Landgrave of Hesse, in the year 1529, invited Luther and Zuinglius to a conference at Marpurg, together with several other of the more eminent doctors who adhered to the respective parties of these contending chiefs. But this measure was not attended with the salutary effects which were expected from it. The divines disputed for four days in presence of the landgrave. Luther attacked Œcolampadius, and Zuinglius was attacked by Melancthon. Zuinglius was accused of heresy, not only on account of his explanation of the nature and design of the Lord's Supper, but also in consequence of the false notions which he was supposed to have adopted concerning the divinity of Christ, the efficacy of the Divine Word, original sin, and some other parts of the Christian doctrine. This illustrious Reformer, however, cleared himself from the greater part of these charges with the most triumphant evidence, and in such a manner as appeared satisfactory even to Luther himself. But their dissension concerning the manner of Christ's presence in the Eucharist still remained; nor could either of the contending parties be persuaded to abandon, or even to modify, their opinions upon that matter. The only advantage, therefore, which resulted from the meeting was, that the jarring doctors formed a kind of truce, by agreeing to a mutual toleration of their sentiments, and leaving to the disposal of Providence the cure of their divisions. (See Hospinian's *Historia Sacramentaria*, part ii.)

The Confession of Augsburg.

In the meantime, news were received that the emperor designed to come into Germany, with a view to terminate all religious differences at the approaching Diet of Augsburg. Having foreseen some of the consequences of those disputes, and, besides, having taken the opinion of men of wisdom, sagacity, and experience, he became gradually more cool in his proceedings, and more impartial in his opinions respecting the contending parties and the merits of the cause. He, therefore, in an interview with the Pope at Bologna, insisted, in the most serious and urgent manner, on the necessity of a general council. His remonstrances and expostulations, however, could not move the Pontiff, who maintained with zeal the papal prerogatives; reproached the emperor with an ill-judged clemency; and alleged that it was the duty of that prince to support the church, and to execute speedy vengeance upon that obstinate and heretical faction who had dared to call in question the authority of Rome. To this discourse the emperor paid no regard, looking upon it as a most iniquitous thing, and a measure directly opposed to the laws of the empire, to condemn unheard so many men who had always approved themselves good citizens, and in other respects deserved well of their country.

Hitherto indeed it was not easy for the emperor to form a clear idea of the matters in debate, since no regular system had as yet been composed by which it might be known with certainty what were the true causes of Luther's opposition to the Pope. The Elector of Saxony, therefore, ordered Luther and other eminent divines to commit to writing the chief articles of their religious system, and the principal points in which they differed from the Church of Rome. Luther, in compliance with this order, delivered to the elector at Torgau seventeen articles which had been agreed upon in a conference at Schwabach in 1529; and hence these received the name of the Articles of Torgau. But though these were deemed by Luther a sufficient declaration of the sentiments of the Reformers, yet it was judged proper to enlarge them, in order to give perspicuity to their arguments and strength to their cause. In this work Melancthon was employed; but in it he showed much deference to the counsels of Luther, expressing his sentiments and doctrine with the greatest elegance and perspicuity, and thus came forth the famous Confession of Augsburg. (See on the whole of this period Merle d'Aubigné's *History of the Reformation*; also Ranke's *History of the Reformation*, vol. iii., on the Diet and Confession of Augsburg. The Confession itself may be seen in Walch, Tittmann, or Hase's Collection of the Symbolical Books of the Prussian Church. The reader may likewise consult with profit the Histories of Scott and Waddington on both the Diet and the Confession.)

This Confession presented to the emperor.

On the 15th of June 1830, Charles arrived at Augsburg, and the Diet was opened five days afterwards. The Protestants received a formal permission to present an account of their tenets to the Diet on the 25th of the same month; and in consequence of this, at the time appointed, Christian Bayer, chancellor of Saxony, read aloud, in the German language, before the emperor and princes assembled, the Confession of Augsburg above mentioned. It contained twenty-eight chapters, of which twenty-one were employed in representing the religious opinions of the Protestants, and the other seven in pointing out the errors and superstitions of the Church of Rome. The princes heard it with the deepest attention. It confirmed some in the principles which they had embraced; it surprised others who had not given much consideration to the subject; and many who before this time had little or no idea of the religious sentiments of Luther, were now not only convinced of their innocence, but delighted with their purity and simplicity. The copies of this Confession, after being read, were delivered to the emperor, being signed by John, Elector of Saxony; George, Marquis of Brandenburg; Ernest, Duke of Lunenburg; Philip, Landgrave of Hesse; Wolfgang, Prince of Anhalt; and by the imperial cities of Nuremberg and Reutlingen.

Attempted refutation of this Confession.

The creatures of the Church of Rome who were present at this Diet employed John Faber, afterwards bishop of Vienna, together with Eck and Cochlæus, to draw up a refutation of the Protestant Confession; and this having been publicly read, the emperor required the Protestant members to acquiesce in it, and put an end to the religious disputes by an unlimited submission to the opinions and doctrines contained in this answer. But this demand was far from being complied with. The Protestants, on the contrary, declared that they were by no means satisfied with the reply of their adversaries, and earnestly desired a copy of it, that they might more fully demonstrate its extreme insufficiency and weakness. But this reasonable request was refused by the emperor, who interposed his supreme authority to prevent any further proceedings in this matter, and solemnly prohibited the publication of any new writings or declarations which might contribute to protract these religious debates. This, however, did not reduce the Protestants to silence. The divines of that communion who had been present at the Diet endeavoured to recollect the arguments and objections employed by Faber, and had again recourse to the pen of Melancthon, who refuted them in an ample and satisfactory manner, in a piece which was presented to the emperor on the 22d of September, but which Charles refused to receive. This answer was afterwards enlarged by Melancthon, when he had obtained a copy of Faber's reply; and was published in the year 1531, with the other pieces that related to the doctrine and discipline of the Lutheran Church, under the title of *Apology for the Confession of Augsburg*.

Severe decree against the Pro testants

Matters now began to draw towards a crisis. There were only three ways of bringing to a conclusion these religious differences: *First*, To grant the Protestants a toleration and privilege of serving God as they thought proper; *secondly*, To compel them to return to the Church of Rome by the violent methods of persecution; or, *thirdly*, That a reconciliation should be made upon fair, and candid, and equitable terms, by engaging each of the parties to temper their zeal with moderation, to abate reciprocally the rigour of their pretensions, and to remit something of their respective claims. The third expedient was most generally approved of, being peculiarly agreeable to all who had at heart the welfare of the empire; nor did even the Pope seem to look upon it with aversion or contempt. Various conferences, therefore, were held between persons eminent for piety and learning upon both sides; and nothing was omitted which might have the least tendency to calm the animosities and heal the divisions which reigned between the contending parties. But the differences were too great to admit of a reconciliation; and therefore the votaries of Rome had recourse to the powerful arguments of imperial edicts and the force of the secular arm. On the 19th of November a severe decree was issued by order of the emperor, in which everything was manifestly adapted to deject the friends of religious liberty, excepting only a faint and dubious promise of engaging the Pope to assemble a general council about six months after the separation of the Diet. In this decree the dignity and excellence of the Catholic religion were extolled beyond measure; a new decree of severity and force was added to that which had been published at Worms against Luther and his adherents; the changes which had been introduced into the doctrine and discipline of the Protestant churches were severely censured; and a solemn order was addressed to the princes, cities and states, who had thrown off the papal yoke to return to their allegiance to Rome, on pain of incurring the indignation and vengeance of the emperor, as the patron and protector of the church.

The league of Smalcald.

Of this formidable decree the Elector of Saxony and the confederated princes were no sooner informed than they assembled in order to deliberate on the measures proper to be taken in such an emergency. In the years 1530 and 1531 they met, first at Smalcald, and afterwards at Frankfort, where they formed a solemn alliance and confederacy, with the intention of defending vigorously their religion and liberties against the dangers and encroachments with which they were threatened by the Edict of Augsburg, without attempting, however, anything offensive against the votaries of Rome; they invited the kings of England, France, and Denmark to join this confederacy, leaving no means unemployed that might strengthen and cement so important an alliance. (See Ranke's *History of the Reformation*, vol. iii., translated by Mrs Austin.)

Invitation to Henry VIII. of England.

This confederacy was at first opposed by Luther, from an apprehension of the calamities and troubles which it might produce; but at last, perceiving the necessity of concert, he consented, though he uncharitably, as well as imprudently, refused to comprehend in it the followers of Zuinglius amongst the Swiss, as well as the German states and cities which had adopted the sentiments and confession of Bucer. In the invitation addressed to Henry VIII. of England, whom the confederate princes were willing to declare the head and protector of their league, the following things, amongst others, were expressly stipulated:—That the king should encourage, promote, and maintain the true doctrine of Christ as it was contained in the Confession of Augsburg, and defend the same at the next general council; that he should not agree to any council summoned by the Bishop of Rome, but protest against it, and neither submit to its decrees nor suffer them to be respected in his dominions; that he should never allow the Roman Pontiff to have any pre-eminence or jurisdiction in his dominions, and should advance 100,000 crowns for the use of the confederacy, engaging to double the sum if necessary,—all which articles the confederate princes were equally obliged to observe upon their part. To these demands the king replied that he would maintain and promote the true doctrine of Christ; but, at the same time, as the true ground of that doctrine lay only in the Holy Scriptures, he would not accept at any one's hand what should be his own faith or that of his kingdom; and therefore desired that they would send over two learned men to confer with him, in order to promote a religious union between him and the confederates. He, however, declared himself of their opinion with regard to the meeting of a free general council, and promised to join with them in all such councils for the defence of the true doctrine; but he thought the regulation of the ceremonial part of religion, being comparatively a matter of indifference, should be left to the choice of each sovereign for his own dominions. Subsequently the king gave them a second and more satisfactory answer; but after the execution of Ann Boleyn this negotiation came to nothing. On the one hand, the king grew cold when he perceived that the confederates were no longer of use to him in supporting the validity of his marriage; and, on the other, the German princes became sensible that they could never succeed with Henry unless they allowed him an absolute dictatorship in matters of religion. (See Froude's *History of England.*)

Peace of Nuremberg.

Whilst everything thus tended to an open war between the opposite parties, the Elector Palatine and the Elector of Mentz offered their mediation, and endeavoured to bring about a reconciliation. The emperor himself, for various reasons, was at this time inclined to peace; for, on the one hand, he stood in need of succours against the Turks, which the Protestant princes refused to grant as long as the Edicts of Worms and Augsburg remained in force; and, on the other, the election of his brother Ferdinand to the dignity of king of the Romans, which had been carried by a majority of votes at the Diet of Cologne in 1531, was by the same princes contested as being contrary to the fundamental laws of the empire. In consequence of all this, after many negotiations and projects of reconciliation, a treaty of peace was concluded at Nuremberg, in 1532, between the emperor and the Protestant princes, on the following conditions, viz.,—that the latter should furnish a subsidy for carrying on the war against the Turks, and acknowledge Ferdinand as lawful king of the Romans; and that the emperor upon his part should abrogate and annul the Edicts of Worms and Augsburg, and allow the Lutherans the free and undisturbed exercise of their religious doctrine and discipline, until a rule of faith should be fixed either in the free general council which was to be assembled in the space of six months, or in a Diet of the empire.

A general council proposed.

Soon after the conclusion of the peace of Nuremberg, John, Elector of Saxony, died, and was succeeded by his son John Frederick, a prince of invincible fortitude and magnanimity, but whose reign was little better than one continued series of disappointments and calamities. The religious truce, however, gave new vigour to the Reformation. Those who had hitherto been only secret enemies of the Roman Pontiff now publicly threw off his yoke, and various cities and provinces of Germany enlisted themselves under the religious banners of Luther. On the other hand, as the emperor had now no other hope of terminating the religious disputes except by the meeting of a general council, he repeated his request to the Pontiff that such a council should be assembled. But Pope Clement VII., whom the history of past councils filled with the greatest uneasiness, endeavoured to retard what he could not with decency refuse. At last, in the year 1533, he made a proposal by his legate to assemble a council at Mantua, Piacenza, or Bologna; but the Protestants refused their consent to the nomination of an Italian council, and insisted that a controversy which had its rise in the heart of Germany should be determined within the limits of the empire. The Pope, by his usual artifices, eluded compliance with this demand, and in 1534 he was cut off by death before any determination could be come to. His successor, Paul III., seemed to show less reluctance to the assembling of a general council, and in 1535 expressed his inclination to convoke one at Mantua; and the year following he actually sent circular letters for that purpose throughout all the states and kingdoms under his jurisdiction. This council was summoned by a bull issued on the 2d of June 1536, to meet at Mantua in the following year. Several obstacles, however, prevented its meeting, one of the most material of which was, that Frederick, Duke of Mantua had no inclination to receive at once so many guests, some of them very turbulent, into the place of his residence. On the other hand, the Protestants were firmly persuaded that, as the council was to be assembled in Italy, and by the authority of the Pope alone, the latter must have an undue influence in that assembly, and consequently that all things would be carried by the votaries of Rome. For this reason they assembled in the year 1537 at Smalcald, where they solemnly protested against this partial and corrupt council, and at the same time had a new summary of their doctrine drawn up by Luther, in order to present it to the assembled bishops if it should be required of them. This summary, which received the title of the Articles of Smalcald, is commonly conjoined with the creeds and confessions of the Lutheran Church.

Fruitless attempts at accommodation.

After the meeting of the general council in Mantua had thus been prevented, many schemes of accommodation were proposed both by the emperor and by the Protestants; but, by the artifices of the Church of Rome all of them came to nothing. In 1541 the emperor appointed a conference to be held at Worms on the subject of religion, between persons of piety and learning chosen from the contending parties. This conference, however, was for certain reasons removed to the Diet which was to be held at Ratisbon that year, and in which the principal subject of deliberation was a memorial presented by a person unknown, containing a project of peace. But the conference produced no other effect than a mutual agreement of the contending parties to refer their matters to a general council, or, if the meeting of such a council should be prevented, to the next German Diet.

Council of Trent. Plan of reformation proposed by the Pope.

This resolution was rendered ineffectual by a variety of incidents which widened the breach, and put off to a future day the deliberations which were designed to heal it. The Pope ordered his legate to declare to the Diet of Spires, assembled in 1542, that he would, according to the promise he had already made, assemble a general council, and that Trent should be the place of its meeting if the Diet had no objection to that city. Ferdinand, and the princes who adhered to the cause of the Pope, gave their consent to this proposal; but it was vehemently objected to by the Protestants, both because the council was summoned by the authority of the Pope only, and also because the place was within the jurisdiction of his holiness; whereas they desired a free council, which should not be biassed by the dictates nor awed by the proximity of the Pontiff. But this protestation produced no effect. Paul III. persisted in his purpose, and issued his circular letters for the convocation of the council, with the approbation of the emperor. In justice to this pontiff, however, it must be acknowledged that he showed that he was not averse to certain measures of a reformatory character. He appointed four cardinals, and three other persons eminent for their learning, to draw up a scheme for the reformation of the church in general, and of that of Rome in particular. The reformation proposed in this plan was indeed extremely superficial and partial; yet it contained some particulars which could scarcely have been expected from those who composed it. They complained of the pride and ignorance of the bishops, and proposed that none should receive orders but learned and pious men, and that care should therefore be taken to have proper masters for the instruction of youth. They condemned translations from one benefice to another, with grants of reservation, non-residence, and pluralities. They proposed that some convents should be abolished; that the liberty of the press should be restrained and limited; that the Colloquies of Erasmus should be suppressed; that no ecclesiastic should enjoy a benefice out of his own country; that no cardinal should have a bishopric; that the questors of St Anthony and several other saints should be abolished; and, which was the best of all their proposals, that the effects and personal estates of ecclesiastics should be given to the poor. They concluded with complaining of the prodigious number of indigent and ragged priests who frequented St Peter's church; and declared that it was a great scandal to see prostitutes lodged so magnificently at Rome, and riding through the streets on fine mules, whilst the cardinals and other ecclesiastics accompanied them in the most courteous manner. This plan of reformation was turned into ridicule by Luther and Sturm; and indeed it left unredressed the greatest grievances of which the Protestants complained.

War between the emperor and the Protestants.

All this time the emperor had been labouring to persuade the Protestants to consent to the meeting of the council at Trent; but when he found them fixed in their opposition to the measure he began to listen to the sanguinary measures of the Pope, and resolved to terminate the disputes by force of arms. Upon this, the Elector of Saxony and the Landgrave of Hesse, who were the chief supporters of the Protestant cause, took proper measures to prevent their being surprised and overwhelmed by a superior force; but before the horrors of war commenced Luther died in peace at Eisleben, the place of his nativity, in the year 1546.

The emperor and the Pope had mutually resolved on the destruction of all who should dare to oppose the Council of Trent. The meeting of this council was to serve as a signal for taking up arms; and accordingly its deliberations were scarcely commenced in 1546 when the Protestants perceived undoubted signs of the approaching storm, and of a formidable union between the emperor and the Pope, which threatened to overwhelm them at once. This year, indeed, there had been a new conference at Ratisbon upon the old subject of accommodating differences in religion; but from the manner in which the debates were carried on, it appeared plain that these differences could only be decided in the field of battle. The Council of Trent, in the meantime, promulgated their decrees; whilst the Reformed princes, in the Diet of Ratisbon, protested against their authority, and were on that account proscribed by the emperor, who raised an army to reduce them to obedience.

Elector of Saxony defeated and taken prisoner.

The Elector of Saxony and the Landgrave of Hesse led their forces into Bavaria against the emperor, and cannonaded his camp near Ingolstadt. It was supposed that this would bring on an engagement, which would probably have been advantageous to the cause of the Reformed; but this was prevented chiefly by the perfidy of Maurice, Duke of Saxony, who invaded the dominions of his uncle. Divisions were also fomented amongst the confederate princes by the dissimulation of the emperor, and France failed in paying the subsidy which had been promised by its monarch,—all which so discouraged the heads of the Protestant party that their army soon dispersed, and the Elector of Saxony was obliged to direct his march homewards. But he was pursued by the emperor, who made several forced marches, with a view to overpower the enemy before he could have time to recover his vigour. The two armies met near Mulberg on the Elbe, on the 24th of April 1547, and, after a sanguinary action, the elector was entirely defeated and taken prisoner. Maurice, who had so basely betrayed him, was now declared Elector of Saxony; and by his entreaties Philip, Landgrave of Hesse, the other chief of the Protestants, was persuaded to throw himself on the mercy of the emperor and to implore forgiveness. To this he consented, relying on the promise of Charles for obtaining pardon and being restored to liberty; but, notwithstanding these expectations, he was unjustly detained prisoner by a scandalous violation of the most solemn convention. It is said that the emperor retracted his promise, and deluded this unhappy prince by the ambiguity of two German words. History, indeed, can scarcely furnish a parallel to the perfidious, mean-spirited, and despotic behaviour of the emperor in the present case. After having received in public the humble submission of the prince on his knees, and set him at liberty in virtue of a solemn treaty, he caused him to be arrested anew without any reason, nay, without any pretence, and kept him a close prisoner for several years. When Maurice remonstrated against this new confinement, the emperor answered that he had never promised that the landgrave should not be imprisoned anew, but only that he should be exempted from perpetual imprisonment; and, to support this assertion, he produced the treaty. (See Ranke's *History*, vol. iv., already referred to; and Robertson's *History of Charles V.*)

The council suddenly dissolved. A formulary drawn up.

The affairs of the Protestants now seemed to be desperate. In the Diet of Augsburg, which was soon afterwards called, the emperor required the Protestants to leave the decision of these religious disputes to the wisdom of the council which was to meet at Trent. The greater part of the members consented to this proposal, being convinced by the powerful argument of an imperial army, which was at hand to dispel the darkness from the eyes of such as might otherwise have been blind to the force of Charles's reasoning. However, this general submission did not produce the effect which was expected from it. A plague which broke out, or was said to have done so in the city, caused the greater part of the bishops to retire to Bologna, by which means the council was in effect dissolved; nor could all the entreaties and remonstrances of the emperor prevail upon the Pope to re-assemble it without delay. During this interval, therefore, the emperor judged it necessary to fall upon some method of accommodating the religious differences, and maintaining peace until the council so long expected should finally be decided on. With this view he ordered Julius Pflug, Bishop of Naumberg, Michael Sidonius, a creature of the Pope, and John Agricola of Eisleben, to draw up a formulary which might serve as a rule of faith and worship, till the council should be assembled. But as this was only a temporary expedient, and had not the force of a permanent or perpetual institution, it thence obtained the name of the *Interim.* (In addition to the other authorities, the reader may consult Gieseler's *Lehrbuch neueren Kirchenges.*, Bonn, 1840.)

This formulary rejected. Melancthon's scheme.

This project of Charles was formed partly with a design to vent his resentment against the Pope, and partly to answer other political purposes. It contained all the essential doctrines of the Church of Rome, though considerably softened by the artful terms which were employed, and which were quite different from those employed before and after this period by the Council of Trent. There was even an affected ambiguity in many of the expressions, which made them susceptible of different meanings, and applicable to the sentiments of both communions. The consequence of all this was, that the imperial formulary was reprobated by both parties. However, it was promulgated with great solemnity by the emperor at Augsburg. The Elector of Mentz, without even asking the opinion of the princes present, gave a sanction to this formulary, as if he had been commissioned to represent the whole Diet. Many remained silent through fear, and that silence was interpreted as a tacit consent. Some who had the courage to oppose it, were reduced by force of arms; and the most deplorable scenes of bloodshed and violence were enacted throughout the whole empire. Maurice, Elector of Saxony, who had hitherto kept neutral, now assembled the whole of his nobility and clergy, in order to deliberate on this critical affair. At the head of the latter was Melancthon, whose word was respected as a law amongst the Protestants. But this man had not the courage of Luther, and was therefore on all occasions ready to make concessions, and to propose schemes of accommodation. In the present case he gave it as his opinion, that the whole of the book called *Interim* could not by any means be adopted by the Protestants; but at the same time he declared that he saw no reason why this book might not be approved, adopted, and received as an authoritative rule in things that did not relate to the essential parts of religion, and which he accounted indifferent. But this scheme, instead of cementing the differences, rendered them worse than ever; and produced a division amongst the Protestants themselves, which might have overthrown the Reformation entirely, if the emperor and the Pope had seized the opportunity.

The Council of Trent re-assembled.

In the year 1549 Pope Paul III. died, and was succeeded by Julius III., who, at the repeated solicitations of the emperor, consented to re-assemble the Council of Trent. A Diet was again held at Augsburg under the cannon of the imperial army, and Charles laid the matter before the princes of the empire. Most of those present gave their consent to it, and amongst the rest Maurice, Elector of Saxony, who consented on the following conditions, namely, that the points of doctrine which had already been decided there should be re-examined; that this examination should be made in presence of the Protestant divines; that the Saxon Protestants should have the liberty of voting as well as of deliberating in the council; and that the Pope should not pretend to preside in that assembly, either in person or by his legates. This declaration of Maurice was read in the Diet, and his deputies insisted upon its being entered into the registers, which the Archbishop of Mentz obstinately refused. (See Sleidan's *Comment.*, lib. xxii., 1556; also Father Paul Sarpi's *History of the Council of Trent*, and Bungener's *History of the Council of Trent.*) This Diet was concluded in the year 1551; and at its breaking up the emperor desired the assembled princes and states to prepare all things for the approaching council, and promised to use his utmost endeavours to procure moderation and harmony, impartiality and charity, in the transactions of that assembly.

The emperor surprised, and forced to conclude a peace.

On the breaking up of the Diet the Protestants took such steps as they thought most proper for their own safety. The Saxons employed Melancthon, and the Würtembergers Brentius, to draw up confessions of faith to be laid before the new council. The Saxon divines, however, proceeded no farther than Nuremberg, having received secret orders from Maurice to stop there; for the elector, perceiving that Charles had formed designs against the liberties of the German princes, resolved to take the most effectual measures for at once crushing his ambition. He therefore entered with the utmost secrecy and expedition into an alliance with the king of France and several of the German princes for the security of the rights and liberties of the empire; after which, having assembled a powerful army in 1552, he marched against the emperor, who lay with a handful of troops at Innspruck, expecting no attack from any quarter. By this sudden and unforeseen accident Charles was so much dispirited that he was willing to make peace almost on any terms. The consequence was, that he concluded a treaty at Passau, which by the Protestants is considered as the basis of their religious liberty. By the first three articles of this treaty, it was agreed that Maurice and the confederates should lay down their arms, and lend their troops to Ferdinand to assist him against the Turks, and that the Landgrave of Hesse should be set at liberty. By the fourth it was agreed that the rule of faith called the *Interim* should be considered as null and void; that the contending parties should enjoy the free and undisturbed exercise of their religion, until a Diet should be assembled to determine amicably the present disputes, which Diet was to meet in the space of six months; and that this religious liberty should continue always, in case it should be found impossible to come to an uniformity in doctrine and worship. It was also determined that all those who had suffered banishment, or any other calamity, on account of their having been concerned in the league or war of Smalcald, should be reinstated in their privileges, possessions, and employments; that the imperial chamber at Spires should be open to the Protestants as well as to the Catholics; and that there should always be a certain number of Lutherans in that high court. To this peace Albert, Marquis of Brandenburg, refused to subscribe, and continued the war against the Roman Catholics, committing such ravages in the empire that a confederacy was at last formed against him. At the head of this conspiracy was Maurice, Elector of Saxony, who died of a wound received in battle in 1553.

Treaty of Augsburg.

The assembling of the Diet promised by Charles was delayed by various incidents; however, it met at Augsburg in 1555, where it was opened by Ferdinand in name of the emperor, and terminated those deplorable calamities which had so long desolated the empire. After various debates, the following acts were passed, on the 25th of September, viz.:—That the Protestants who followed the Confession of Augsburg should be for the future considered as entirely free from the jurisdiction of the Roman Pontiff, and from the authority and superintendence of the bishops; that they were left at perfect liberty to enact laws for themselves relating to their religious sentiments, discipline, and worship; that all the inhabitants of the German empire should be allowed to judge for themselves in religious matters, and to join that church whose doctrine and worship they thought the purest and most consonant to the spirit of true Christianity; and that all those who should injure or persecute any person under religious pretences, and on account of their opinions, should be declared and proceeded against as public enemies of the empire, invaders of its liberty, and disturbers of its peace.

Account of the Reformation in Sweden.

Thus was the Reformation established in many parts of the German empire, where it continues to this day; nor have the efforts of the Catholic powers at any time been able to suppress it, or even to prevent it from gaining ground. It was not, however, in Germany alone that a reformation of religion took place. About the same time almost all the kingdoms of Europe began to open their eyes to the truth. The Reformed religion was propagated in Sweden, soon after Luther's rupture with the Church of Rome, by one of his disciples, named Olaus Petri. The zealous efforts of this missionary were seconded by Gustavus Vasa, whom the Swedes had raised to the throne instead of Christiern, King of Denmark, who by his horrid barbarity lost the crown (A.D. 1523-61). This prince, however, was as prudent as he was zealous; and as the minds of the Swedes were in an unsettled state, he wisely avoided any show of vehemence and precipitation in spreading the new doctrine. Accordingly, the first object of his attention was the instruction of his people in the sacred doctrines of the Holy Scriptures; and for this purpose he invited into his dominions several learned Germans, and spread abroad throughout the kingdom the Swedish translation of the Bible which had been made by Olaus Petri. Some time after this, in 1526, he appointed a conference at Upsal, between this Reformer and Peter Gallius, a zealous defender of the ancient faith, in which each of the champions was to bring forth his arguments, that it might be seen on which side the truth lay. In this dispute Olaus obtained a signal victory, which contributed much to confirm Gustavus in his persuasion of the truth of Luther's doctrine, and to promote its progress in Sweden. The following year another event gave the finishing stroke to its propagation and success. This was the assembly of the states at Westeraas, where Gustavus recommended the doctrine of the Reformers with such zeal that, after warm debates fomented by the clergy, it was unanimously resolved that the reformation introduced by Luther should be adopted in Sweden. This resolution was principally owing to the firmness and magnanimity of Gustavus, who declared publicly that he would lay down the sceptre and retire from the kingdom, rather than rule a people enslaved by the orders and authority of the Pope, and more controlled by the tyranny of their bishops than by the laws of their monarch. The papal empire in Sweden was now overthrown, and Gustavus declared head of the church. (See the Histories of Gerdes and Schroeckh.)

Reformation in Denmark.

In Denmark the Reformation was introduced as early as the year 1521, in consequence of the ardent desire discovered by Christiern II. of having his subjects instructed in the doctrines of Luther. This monarch, notwithstanding his cruelty, for which his name has been rendered odious, was nevertheless desirous of delivering his dominions from the tyranny of the Church of Rome. For this purpose, in the year 1520 he sent for Martin Reynhard, one of the disciples of Carlstadt, and appointed him professor of divinity at Copenhagen; and after the death of this man, which happened in 1521, he invited Carlstadt himself to fill that important place. Carlstadt accepted of this office indeed, but in a short time returned to Germany; upon which Christiern used his utmost endeavours, but in vain, to engage Luther to visit his dominions. However, the progress of Christiern in reforming the religion of his subjects, or rather of advancing his own power above that of the church, was checked in the year 1523 by a conspiracy, in consequence of which he was deposed and banished; his uncle Frederick, Duke of Holstein and Schleswick, being appointed his successor.

Frederick conducted the Reformation with much greater prudence than his predecessor. He permitted the Protestant doctors to preach publicly the sentiments of Luther, but did not venture to change the established government and discipline of the church. However, he contributed greatly to the progress of the Reformation by his successful attempts in favour of religious liberty, in an assembly of the states held at Odensee in 1527. Here he procured the publication of a famous edict, by which every subject of Denmark was declared free to adhere either to the tenets of the Church of Rome or to the doctrine of Luther. The papal tyranny was totally destroyed by his successor Christiern III. He began by suppressing the despotic authority of the bishops, and restoring to their lawful owners a great part of the wealth and possessions which the church had acquired by various stratagems. This was followed by a plan of religious doctrine, worship, and discipline, laid down by Bugenhagen, whom the king had sent for from Wittenberg for the purpose; and in 1539 an assembly of the states at Odensee gave their solemn sanction to all these transactions. (See the works of Gramm and Ranke; also Pontoppidan's *History of the Reformation in Denmark*, 1734; and especially the work of Münter, *Kirchengeschichte von Danemarck und Norwegen*, 1833, 3 vols.)

Reformation in France.

In France also the Reformation began very early to make some progress. Margaret, Queen of Navarre, and sister of Francis I., the perpetual rival of Charles V., was a great friend to the new doctrine; and it appears that, as early as the year 1523, there were in several of the provinces of France great numbers of people who had conceived the greatest aversion both to the doctrine and tyranny of the Church of Rome, amongst whom were many of the first rank and dignity, and even some of the episcopal order. But as their number increased daily, and troubles and commotions were excited in several places on account of the religious differences, the authority of the king intervened, and many persons eminent for their virtue and piety were put to death in the most barbarous manner. Indeed, Francis, who had either no religion at all, or, at best, no fixed and consistent system of religious principles, conducted himself towards the Protestants in such a manner as best answered his private views. Sometimes he resolved to invite Melancthon into France, probably with a view to please his sister the Queen of Navarre, whom he loved tenderly, and who had strongly imbibed the Protestant principles. At other times he exercised the greatest cruelty towards the Reformed; and once made the following absurd declaration, that if he thought the blood in his arm was tainted by the Lutheran heresy, he would have the arm cut off; and that he would not spare even his own children if they entertained sentiments contrary to those of the Catholic Church. About this time Calvin began to attract the attention of the public, but more especially that of the Queen of Navarre. His zeal exposed him to danger; and as Francis was daily committing to the flames the friends of the Reformation, he was placed more than once in the most perilous situation, from which he was only delivered by the interposition of the Queen of Navarre. He therefore retired from France to Bâle in Switzerland, where he published his *Christian Institutes*, and afterwards became celebrated in the history of Protestantism. (See CALVIN.)

Those amongst the French who first renounced the jurisdiction of the Church of Rome are commonly called Lutherans by the writers of those early times. Hence it has been supposed that they had all imbibed the peculiar sentiments of Luther. But this appears not to have been the case; for the vicinity of the cities of Geneva, Lausanne, and some others, which had adopted the doctrine of Calvin, produced a remarkable effect upon the French Protestant churches; insomuch that, about the middle of this century, they all entered into communion with the Church of Geneva. The French Protestants were, by way of contempt, called Huguenots by their adversaries. Their fate was very severe, being persecuted with unparalleled fury; and though several princes of the blood, and many of the first nobility, had embraced their sentiments, yet in no part of the world did the Reformers suffer so much. At last all commotions were quelled by the fortitude and magnanimity of Henry IV., who in the year 1598 granted all his subjects full liberty of conscience by the famous Edict of Nantes, and seemed to have thoroughly established the Reformation throughout his dominions. During the minority of Louis XIV., however, this edict was revoked by Cardinal Mazarin, since which time the Protestants have often been cruelly persecuted; nor has the profession of the Reformed religion in France been at any time so safe as in most of the other countries of Europe. (Besides the Histories of Beza, Benoit, and Salig, the reader is referred to the third volume of Merle d'Aubigné.)

Reformation in the Netherlands.

In the other parts of Europe the opposition to the Church of Rome was but faint and ambiguous before the Diet of Augsburg. Prior to that period, however, it appears, from undoubted testimony, that the doctrine of Luther had made a considerable, though probably a secret, progress throughout Spain, Hungary, Bohemia, Britain, Poland, and the Netherlands; and had in all these countries gained many friends, of whom several repaired to Wittenberg, in order to enlarge their knowledge by means of Luther's conversation. Some of these countries threw off entirely the yoke of Rome, and in others a prodigious number of families embraced the principles of the Reformed religion. It is certain, indeed, and some Roman Catholics themselves acknowledged it without hesitation, that the papal doctrines and authority would at once have fallen into ruin in all parts of the world had not the force of the secular arm been employed to support the tottering edifice. In the Netherlands particularly the most grievous persecutions took place, so that by the Emperor Charles V. upwards of a hundred thousand were destroyed, whilst still greater cruelties were exercised upon the people by his son Philip II. The revolt of the United Provinces, however, and motives of real policy, at last put a stop to these furious proceedings; and although in many provinces of the Netherlands the establishment of the Catholic religion was still continued, the Protestants have been long free from the danger of persecution on account of their principles. (The reader may consult, after the Histories of Gerdes and Schrœckh, Brandt's *History of the Reformation in the Low Countries*, 4 vols., translated from the Dutch, 1720–23.)

Reformation in Italy.

The Reformation made considerable progress in Spain and Italy soon after the rupture between Luther and the Roman Pontiff. In all the provinces of Italy, but more especially in the territories of Venice, Tuscany, and Naples, the superstition of Rome lost ground, and great numbers of people of all ranks expressed an aversion to the papal yoke. In the year 1546, this occasioned violent and dangerous commotions in the kingdom of Naples; which, however, were at last quelled by the united forces of Charles V., and his viceroy Don Pedro di Toledo. In several places the Pope put a stop to the progress of the Reformation, by letting loose the inquisitors, who spread dreadful marks of their barbarity throughout the greater part of Italy. These formidable ministers of persecution put so many to death, and perpetrated such horrible acts of cruelty and oppression, that most of the Reformed consulted their safety by a voluntary exile, whilst others returned to the religion of Rome, at least in external appearance. But the Inquisition which frightened into the profession of Popery several Protestants in other parts of Italy, could never make its way into the kingdom of Naples, nor could either the authority or the entreaties of the Pope engage the Neapolitans to admit even visiting inquisitors. (See the admirable *History of the Progress and Suppression of the Reformation in Italy*, by the elder M'Crie, Edinburgh, 1833; also Gieseler's *Lehrbuch*, vol. i.)

Reformation in Spain.

In Spain, several persons embraced the Protestant religion, not only from the controversies of Luther, but even from those divines whom Charles V. had brought with him into Germany in order to refute the doctrines of the Reformer. For these doctors had imbibed the pretended heresy instead of refuting it, and propagated it more or less on their return home. But the Inquisition, which could obtain no footing in Naples, reigned triumphant in Spain, and by the most dreadful methods frightened the people back into Popery, and suppressed the desire of exchanging their superstition for a more rational plan of religion. It was indeed presumed that Charles himself died a Protestant; and it seems to be certain that when the approach of death had dissipated those schemes of ambition and grandeur which had so long blinded him, his sentiments became much more rational and agreeable to Christianity than they had ever been before. All the ecclesiastics who had attended him, as soon as he expired, were sent to the Inquisition, and committed to the flames, or put to death by some other method equally terrible. Such was the fate of Augustin Casal, the emperor's preacher; of Constantine Pontius, his confessor; of Egidius, whom he had named to the bishopric of Tortosa; of Bartolomeo de Caranza, a Dominican, who had been confessor to Philip and Mary of England; with many others of less note. (See M'Crie's *History of the Progress and Suppression of the Reformation in Spain*, Edin. 1829.)

Reformation in England.

In England the principles of the Reformation began to be adopted as soon as an account of Luther's doctrines could be conveyed thither. In that kingdom there were still remains of the sect called Lollards, whose doctrine resembled that of Luther; and amongst whom consequently the sentiments of the Reformer gained great credit. (See LOLLARDS.) Henry VIII., King of England, was at that time a violent partisan of the Church of Rome, and had a particular veneration for the writings of Thomas Aquinas. Being informed that Luther spoke of his favourite author with contempt, he conceived a violent prejudice against the Reformer, and even wrote against him, as has been already alluded to. Luther did not hesitate about writing against his majesty, overcame him in argument, and treated him with very little ceremony. The first step towards public reformation, however, was not taken until the year 1529. Great complaints had been made in England from a very early period respecting the usurpations of the clergy; and the prevalence of the Lutheran opinions rendered these complaints more loud and general than before. The House of Commons, finding the occasion favourable, passed several bills restraining the impositions of the clergy; but what threatened the ecclesiastical order with the greatest danger were the severe reproaches thrown out in the House, almost without opposition, against the dissolute lives, ambition, and avarice of the priests, and their continual encroachments on the privileges of the laity. The bills for regulating the clergy met with opposition in the House of Lords; and Bishop Fisher imputed them to want of faith in the Commons, and to a formed design, proceeding from heretical and Lutheran principles, of robbing the church of her patrimony, and overturning the national religion. The Commons, however, complained to the king, by their speaker, Sir Thomas Audley, of these reflections thrown out against them; and the bishop was obliged to retract his words. Though Henry had not the least idea of rejecting any even of the most absurd observances of the Catholic Church, yet as the oppressions of the clergy were very ill suited to the violence of his own temper, he was pleased with every opportunity of lessening their power. In the Parliament of 1531 he showed his design of humbling the clergy in the most effectual manner. An obsolete statute was revived, from which it was pretended that to submit to the legatine which had been exercised by Cardinal Wolsey was criminal. By this stroke the whole body of clergy was at once declared guilty. They were too well acquainted with Henry's disposition, however, to reply, that their ruin would have been the certain consequence of their not submitting to Wolsey's commission, which had been given by royal authority. Instead of making any defence of this kind, they chose to throw themselves on the mercy of their sovereign; which, however, cost them some L.118,840 to procure. A confession was likewise extorted from them, that the king was protector and supreme head of the Church of England; though some of them had the dexterity to get a clause inserted which invalidated the whole submission, namely, "in as far as is permitted by the law of Christ." The king having thus begun to reduce the power of the clergy, kept no bounds with them afterwards. He did not indeed attempt any reformation in religious matters; nay, he persecuted most violently such as did in the least degree attempt anything of the kind. Indeed, the most essential article of his creed seems to have been his own supremacy; for whoever denied this, whether Protestant or Papist, was sure to suffer the most severe penalties. He died in the year 1547, and was succeeded by his only son, Edward VI. This amiable prince gave new spirit and vigour to the Protestant cause, and was its brightest ornament, as well as its most effectual support. He encouraged learned and pious men of foreign countries to settle in England, and addressed a particular invitation to Martin Bucer and Paul Fagius, whose moderation added a lustre to their other virtues; in hopes that, by the ministry and labours of these eminent men, in concert with those of the friends of the Reformation in England, he might purge his dominions from the fictions of Popery, and establish in their room the pure doctrines of Christianity. For this purpose, he issued the wisest orders for the restoration of true religion; but his reign was too short to accomplish fully such a glorious purpose. In the year 1553 he was taken from his loving and afflicted subjects, whose sorrow was great, and suited to their loss. His sister Mary, the daughter of Catharine of Aragon, from whom Henry had been divorced, blindly bigoted to the Church of Rome, and a princess whose natural character, like the spirit of her religion, was despotic and cruel, succeeded him on the throne, and imposed anew the arbitrary laws and the tyrannical yoke of Rome upon the people of England. Nor were the methods which she employed in the cause of superstition better than the cause itself, or tempered by any sentiments of equity or compassion. Barbarous tortures, and death in the most shocking forms, awaited those who opposed her will, or made the least stand against the restoration of Popery. And amongst many other victims, the learned and pious Cranmer, Archbishop of Canterbury, who had been one of the most efficient instruments of the Reformation in England, fell a sacrifice to her fury. But this odious scene of persecution was happily concluded in the year 1558, by the death of the queen, who left no issue; and as soon as her successor Elizabeth ascended the throne all things assumed a new aspect. The glorious period of this reign was alike eminent for religious knowledge and for daring genius, for civil prosperity and for martial glory. Elizabeth, whose sentiments, and councils, and projects, breathed a spirit superior to the natural softness and delicacy of her sex, exerted this vigorous and masculine spirit in the defence of oppressed conscience and expiring liberty; broke anew the despotic yoke of papal authority and superstition; and, delivering her people from the bondage of Rome, established that form of religious doctrine and ecclesiastical government which still subsists in England. This religious establishment differed in some respects from the plan which had been formed by those whom Edward VI. had employed for promoting the cause of the Reformation, and approached nearer to the rites and discipline of former times; though it is widely different, and in the most important point entirely opposite to the principles of the Roman Catholic hierarchy. (Burnet, Neal, Collier, Soames, Carwithen, have written Histories of this period; and a comparatively recent and very spirited outline of the English Reformation will be found in Blunt's *Sketch of the Reformation in England*, Lond. 1832.)

Reformation in Ireland.

The cause of the Reformation underwent in Ireland the same vicissitudes and revolutions which had attended it in England. When Henry VIII., after the abolition of the papal authority, was declared supreme head of the Church of England, George Brown, a native of England, and a monk of the Augustinian order, whom that monarch had created, in the year 1535, archbishop of Dublin, began to act with the utmost vigour in consequence of this change in the hierarchy. He purged the churches within his diocese from superstition in all its various forms; pulled down images; destroyed relics; abolished absurd and idolatrous rights; and, by the influence as well as authority he had obtained in Ireland, caused the king's supremacy to be acknowledged in that nation. Henry soon afterwards showed that this supremacy was by no means a vain title; for he banished the monks out of that kingdom, confiscated their revenues, and destroyed their convents. In the reign of Edward VI. still further progress was made in the removal of popish superstitions by the zealous labours of Archbishop Brown, and the auspicious encouragement he granted to all who exerted themselves in the cause of the Reformation. (See *The Harleian Miscellany*, which contains a Life of Brown, vol. v., No. 73, Lond. 1745.) The death of this young prince, however, and the accession of Queen Mary, had nearly changed the face of affairs in Ireland as much as in England; but her designs were disappointed by a very curious adventure, of which the following account has been copied from the papers of Richard, Earl of Cork.

Curious disappointment.

"Queen Mary having dealt severely with the Protestants in England, about the latter end of her reign, signed a commission for to take the same course with them in Ireland; and to execute the same with greater force, she nominates Dr Cole one of the commissioners. The doctor coming, with the commission, to Chester on his journey, the mayor of that city, hearing that her majesty was sending a messenger into Ireland, and he being a churchman, waited on the doctor, who in discourse with the mayor taketh out of a cloke-bag a leather box, saying unto him, Here is a commission that shall lash the heretics of Ireland, calling the Protestants by that title. The good woman of the house being well affected to the Protestant religion, and also having a brother named John Edmonds of the same persuasion, then a citizen in Dublin, was much troubled at the doctor's words; but watching her convenient time, while the mayor took his leave, and the doctor complemented him down the stairs, she opens the box, takes the commission out, and places in lieu thereof a sheet of paper with a pack of cards wrapt up therein, the knave of clubs being faced uppermost. The doctor coming up to his chamber, suspecting nothing of what had been done, put up the box as formerly. The next day going to the water-side, wind and weather serving him, he sails towards Ireland, and landed on the 7th of October 1558 at Dublin. Then coming to the castle, the Lord Fitzwalters being lord-deputy, sent for him to come before him and the Privy-Council; who, coming in, after he had made a speech relating upon what account he came over, he presents the box unto the lord-deputy; who causing it to be opened, that the secretary might read the commission, there was nothing save a pack of cards with the knave of clubs uppermost; which not only startled the lord-deputy and council, but the doctor, who assured them he had a commission, but knew not how it was gone. Then the lord-deputy made answer: Let us have another commission, and we will shuffle the cards in the meanwhile. The doctor being troubled in his mind, went away, and returned into England, and coming to the court obtained another commission; but staying for a wind on the water-side, news came to him that the queen was dead; and thus God preserved the Protestants of Ireland." Queen Elizabeth was so delighted with this story, which was related to her by Lord Fitzwalter on his return to England, that she sent for Elizabeth Edmonds, whose husband's name was Mattershad, and gave her a pension of L.40 a year during her life. (See Phelan's *Policy of the Roman Catholic Church in Ireland*, London, 1827; and especially Dr Seaton Reid's *History of the Presbyterian Church in Ireland*, Edinburgh, 1834. The reader may likewise consult Dr Mant's *History of the Church of Ireland*, London, 1840.)

Reformation in Scotland.

In Scotland the seeds of the Reformation were very early sown by several noblemen who had resided in Germany during the religious disputes there; but for many years it was suppressed by the power of the Pope, seconded by severe laws and not a few executions. The most eminent opponent of the papal jurisdiction was John Knox, a disciple of Calvin, and a man of great zeal and invincible fortitude. (See KNOX.) On all occasions he raised the drooping spirits of the Reformers, and encouraged them to go on with their work, notwithstanding the opposition and treachery of the queen-regent, until at last, in 1561, by the assistance of an English army sent by Elizabeth, Popery was in a manner totally extirpated from every part of the kingdom. From this period the form of doctrine, worship, and discipline established by Calvin at Geneva has had the ascendancy in Scotland. (See the Histories of Calderwood, Knox, and Cook; also M'Crie's *Life of John Knox;* Robertson's *History of Scotland;* Scott's *Protestant Reformers of Scotland;* and the Histories of Spottiswood, Keith, and Tytler.)

REFRACTION. See ASTRONOMY, and OPTICS.

REGALIA, politically considered, is the privileges, prerogative, and right of property belonging, in virtue of his office, to the sovereign of a state. The most common signification of the word, however, is the heraldic one, in which it is applied to the royal insignia. The regalia of England are the crown, the sceptre, the virge, St Edward's staff, the orb or mound, the sword of mercy, the two swords of justice, the ring of alliance, the armillæ or bracelets, the spurs of chivalry, and sundry royal vestments. These are preserved, all except the royal vestments, in the jewel-office in the Tower of London. The insignia of Scottish royalty are a crown, a sceptre, and a sword of state. They are deposited in the crown-room of Edinburgh Castle.

REGARDANT. See HERALDRY.

REGATTA, originally a Venetian term applied to a great fête in which the gondoliers contended for superiority in rowing, but which has now been naturalized into all the languages of Europe, in which it is employed to designate any brilliant species of boat-race.

REGENT, one who exercises the power without the name of a king. In a hereditary monarchy the appointment of a regent becomes necessary on the crown descending to a minor too young to be entrusted with the regal office, or in case of mental incapacity, or incapacity by illness which will probably be of long duration, or on absence from the realm. There have been several instances in English history of the appointment of a regent, usually styled a *protector*, during the sovereign's minority; the last occurred during the minority of Edward VI., when the protector, the Duke of Somerset, was uncle to the sovereign. Blackstone, in his *Commentaries* (book i., c. 7), gives a summary of the appointment of regents in England during the nonage of the heir. In cases of ill health there existed no recognised constitutional rule; so that on the illness of George III. it became a matter of hot dispute whether his eldest son, then of full age, should become regent, or whether the choice and nomination of that grand functionary rested with the Parliament. The king's recovery, meanwhile, destroyed the problem; but on a relapse all parties were unanimous in the choice of the Prince of Wales. The regency of the kingdom of Great Britain and Ireland, in case of minority upon the demise of the present sovereign, is provided for by the "Regency Bill," 3 and 4 Vict., c. 52.

REGGIO (anc. *Rhegium Julii*), a town of Naples, capital of the province of Calabria Ultra I., stands near the southern extremity of the Italian peninsula, on the Straits of Messina, and 9 miles S.E. of that town. Notwithstanding that the Apennines rise in barren, rugged masses behind the town, the surrounding country is almost unrivalled for its clear atmosphere, delicious climate, and luxuriant vegetation. Groves of oranges and lemons extend for miles around, and in the gardens grow many exotics from various countries. The scenery, too, is exceedingly beautiful, especially when the outline of the Sicilian hills stands out against the setting sun, and the huge mass of Ætna looms in the distant south. From a broad street called the Marina, running along the shore, the town gradually rises with its handsome buildings and broad streets, laid out on a regular plan. The cathedral and other churches, the convents, the college, theatre, hospital, and foundling asylum are conspicuous among the public edifices. Manufactures of silk, linen, hosiery, oils, &c., are carried on here, and there is some trade, especially in silk and oil. The modern city has been entirely built since 1783, when it was laid in ruins by a tremendous earthquake. Pop. 20,000. (See RHEGIUM.)

REGGIO (anc. *Rhegium Lepidi*), a town of Italy, in the duchy and 15 miles W. of Modena, on the canal of Tassone, leading to the Po. A handsome and well-built though extremely dull town, defended by walls and a castle, it contains a cathedral of the fifteenth century, adorned with marble columns, and containing several monuments by Clementi, as well as his tomb. Another beautiful church is that of Madonna della Ghiara, in the shape of a Greek cross, surmounted by five cupolas, and adorned with many fresco paintings. Besides many other churches and convents, there are at Reggio a public library of 30,000 volumes, a theatre, Jesuit college, lyceum, and lunatic asylum. Silk and linen fabrics are made here; and various delicately-carved articles in ivory, horn, and wood. The town has an active trade in wine, cattle, and other articles; and a fair held here annually is much frequented. Reggio is celebrated as the birthplace of Ariosto. A house is pointed out by tradition as that where the poet first saw the light, though, according to some, the event must have taken place in the castle. Pop. about 20,000.

REGIFUGIUM, or FUGALIA (*the king's flight*), a festival of Rome, celebrated annually on the 24th of February, and, according to some ancient Calendaria, on the 24th of May. Verrius and Ovid say it was meant to memorialize the flight of King Tarquin from Rome, while a number of other writers, both ancient and modern, concur in regarding it as commemorative of the symbolical flight of the Rex Sacrorum from the comitium.

REGILLUS, LAKE OF, situated in the territory of Tusculum in Latium, was celebrated in Roman story as the scene of a great battle. Here it was that the dictator A. Postumius Albus engaged the Latin confederacy under the expelled Tarquins and Mamilius of Tusculum; and here it was that Castor and Pollux appeared on two white steeds, heading the charge of the Roman cavalry against the flying foe. At the present day Regillus has not been identified with certainty; but it is now generally supposed to be the same as the *Lago di Cornufelle*. That lake, about half a mile in diameter, lying at the foot of the hill on which the modern Frascati is built, is of a singular character. Its basin is evidently the crater of an extinct volcano. Its waters have been completely drained away by an emissary made in the seventeenth century. The dry channel during summer swarms with vipers, so that it is dangerous to approach it. The ruins of an old Roman villa are the only vestige of a building in its immediate neighbourhood.

REGIMEN. See DIETETICS.

REGIMENT. See ARMY.

REGIOMONTANUS. See MÜLLER, *Johann.*

REGIS, PIERRE SYLVAIN, a Cartesian philosopher, was born in Agenois in the year 1632. He studied languages and philosophy under the Jesuits at Cahors, and subsequently theology at the Sorbonne at Paris. He heard Rohault's lectures on the Cartesian philosophy, which soon determined him to give up theology. In 1665 he was appointed to the philosophical chair at Toulouse, where his eloquence attracted great masses of the people. The magistrates, the learned, the ecclesiastics, and the very women, all affected to abjure the ancient philosophy. In 1680 he returned to Paris, where the concourse which flocked to him was such that the Peripatetics got alarmed. They applied to the Archbishop of Paris, who thought it expedient, in the name of the king, to put a stop to the lectures, which accordingly were discontinued for several months. The whole life of Regis was spent in propagating the new philosophy. In 1690 he published his *Cours entier de philosophie, ou Système général selon les principes de Descartes*, 4 vols. 4to, in which he embraced logic, metaphysics, physics, and morals. In the two following years he was occupied with the publication of his refutations of Huet, Duhamel, and Spinoza. In 1691 there appeared at Paris his *Réponse au livre qui a pour titre* Censura philosophiæ Cartesianæ; in 1692 his *Réponse aux Réflexions critiques de M. Duhamel sur le système Cartésien de la philosophie de M. Regis;* and in 1704 his last work, *L'Usage de la Raison et de la Foi, ou l'Accord de la Raison et de la Foi*, followed by an attack on Spinoza. Regis was made a member of the Academy of Sciences in 1699, and he died in 1707. The reader may consult the *Eloge de Régis* by Fontenelle, the *Histoire de la Philosophie du 17th siècle*, by Damiron, vol. ii., p. 61, &c., and Bouillier's notice of him in the *Dictionnaire des Sciences Philosophiques.*

REGISTRATION.

REGISTRATION, *General*, of Births, Baptisms, Marriages, Deaths, and Burials in England and Wales. The first known public authority under which registers recording births or baptisms, marriages, deaths, or burials, were systematically kept in England, was an injunction issued in September 1538 (30 Hen. VIII.) by Thomas, Lord Cromwell, lord privy seal and vicegerent to the king, which enjoined that in every parish a register-book should be kept in a coffer with two locks by the parson, vicar, or curate, and churchwardens; and that every Sunday, in the presence of one of the churchwardens, the parson, &c., should enter in a register-book a written record of the dates and names of the weddings, christenings, and burials of the preceding week; by neglect of which duty he incurred a fine of three shillings and fourpence, to be employed in the repair of the church.

In 1547 an injunction was issued by Edward VI. similar to that of 1538, excepting only that the penalty was directed "to be employed to the poore-box" of the parish.

Inquiry was directed, at the instance of Cardinal Pole, under Philip and Mary, in the years 1555 and 1557, whether the clergy had complied with these directions; and in the first year of Queen Elizabeth, 1559, a further injunction was issued, which differed from that of Edward VI. in 1547 only in directing that the penalty should be divided between the poor-box and the repair of the church. These injunctions were not very strictly observed, as appears by the preamble of a bill to "authorize every archbishop and bishop to erect one office of registership of all the church-books, to be kept in every diocese," which, in March 1563, was read a first time in the House of Commons, but did not pass.

The great importance of registration was in 1590 represented to the Lord-Treasurer Burghley, who, impressed with the force of the representation, communicated a plan to the Archbishop of Canterbury. Nothing, however, appears to have been done in consequence until October 1597, when a constitution was made by the archbishop, bishops, and clergy of the province of Canterbury, and approved by the queen, which notices the very great utility of parish registers, and gives minute directions for keeping them, and for the transmission of a transcript yearly to the diocesan registrar. It appears, too, that persons were appointed for the purpose of ascertaining if the several orders had been complied with; and that every minister, at institution, was required to declare that he would "keep the register-book according to the queen's majesty's injunctions."

In 1603, the first year of the reign of James I., another injunction was issued similar to that of 1597, with the important addition of a clause appointing that the ancient registers, so far as they could be procured, but especially since the beginning of the reign of Elizabeth, should be copied into a parchment-book, to be provided by every parish; after which nothing more appears to have emanated, either from the ecclesiastical or civil authorities, on this subject, till the time of the Long Parliament, when the following entry in the Journal of the House of Commons gives evidence of attention to the importance of registration:—

"Anno 1644, Dec. 6. Ordered, that it be referred to the committee for bringing in the ordinance for the establishing the directory, to bring in a clause in that ordinance, for registering the time of baptizing of children, and their parents' names, and for registering of burials." In the same year an ordinance was made, directing that in every parish or chaplery in England and Wales the minister and other church-officers should keep a register of birth and baptism, of marriage and of burial; and that all persons reasonably desiring it might search therein and obtain copies.

In August 1653, in pursuance of the recommendations of a law-reform committee appointed in the preceding year, and including many eminent persons, an act was passed, which directed that in every parish a register-book should be provided for registering all marriages, births, and burials in the parish; and that the custody of such book, and the duty of registration, should be given to a person, to be called the parish registrar, appointed by the parishioners chargeable to the poor, and approved by a justice of the peace. It was also enacted that extra-parochial places, or small parishes, might be united, for the purposes of registration, to other parishes, by the justices at their sessions; and that all existing register-books should be kept by the registering officers appointed under that act.

This act was not confirmed at the Restoration, and the business of registration reverted to the clergy of the established church. During the reigns of Charles II. and James II. nothing was done with respect to registers, except that, by a clause in the act of 30 Car. II., c. 3, entitled "An Act for Burying in Woollen," it was enacted that all clergymen "do, within their respective parishes, precincts, and places, take an exact account, and keep a register, of all and every person or persons buried in his or their respective parishes or precincts, or in such common burial-places as their respective parishioners are usually buried."

In the reign of William III. registration was rendered a source of revenue. The act of 6 and 7 William III., c. 6, granted duties on births, marriages, and burials, and compelled the clergy, under a penalty of L.100, to keep an exact register of all persons born, christened, married, or buried in their respective parishes, to which register the collector of the tax, and all persons concerned, might have free access without fee. It thus imposed on the clergyman the onerous duty of acting gratuitously as a civil functionary, and collecting information of all births within his parish, without distinction of sect, and irrespective of baptism; a duty the difficulty of which was rendered greater by the attempts of the parents to conceal the birth, in order to elude the payment of the tax. With a view to obviate this objection, an act was passed in the following year (7 and 8 William III., c. 35), which provided that parents should, within five days after birth, give notice of the day of the birth to the clergyman, under a penalty of 40s., and that the clergyman should, under a like penalty, register such birth, for which the parents were to pay 6d.; and by the 4th of Anne, c. 12, the clergy were relieved from the ruinous penalties incurred under the act of 6 and 7 William III., c. 6, in all cases where the duties had been really paid.

In 1751 a bill was introduced into Parliament by Mr Potter (son of Archbishop Potter), for providing a general registry of births, deaths, and marriages, and for taking a yearly account of the population and number of paupers. Although strongly opposed, this bill passed the House of Commons, but was rejected by the Lords.

The 26th Geo. II., c. 33, an act "to prevent clandestine marriages," directed the church-wardens of every parish to provide books of vellum, or good and durable paper, for the registration of marriages. By the 23d of Geo. III., c. 67, a stamp-duty of 3d. was imposed upon every registered entry of burial, marriage, birth, or christening, to be demanded by the clergyman from the undertaker, or from the parties married, or from the parents of the child whose birth or christening had been registered. By 25 Geo. III., c. 75, the provisions of that act were extended to dissenting ministers. These measures excited much objection, and were repealed in 1794.

The next legislative measure affecting registers was the 52 Geo. III., c. 146, entitled, "An Act for the better regulating and preserving Parish and other Registers of Births, Baptisms, Marriages, and Burials in England." After reciting that "the amending the manner and form of keeping and of preserving registers of baptisms, marriages, and burials of his Majesty's subjects in the several parishes and places in England, will greatly facilitate the proof of pedigrees of persons claiming to be entitled to real or personal estates, and be otherwise of great public benefit and advantage," it enacts that, after the 31st of December 1812, registers of baptisms, marriages, and burials, according to the rites of the Established Church, shall be made and kept by the officiating minister of every parish and chapelry, in books to be provided by the king's printer, at the expense of the respective parishes, according to the forms contained in schedules annexed to that act. These schedules contain the following particulars: In case of *baptism*,—when baptized; child's Christian name; parents' Christian names and surnames; abode; quality, trade, or profession; by whom the ceremony was performed. In case of *marriage*,—the name and parish of the man; the same of the woman; when married; whether by banns or license; whether by consent of parents or guardians; when; by whom; signature of officiating minister of the parties married, and of two witnesses. In case of *burial*,—the name; abode; when buried; age; by whom the ceremony was performed.

The registers of baptism, marriage, and burial were to be kept in separate books, and signed within seven days after each ceremony had been performed. Annual copies were to be made, verified, and signed by the officiating minister, and attested by the church-wardens, and transmitted by them yearly to the registrar of the diocese; which registrar must report thereon to his bishop; must deposit such copies in a safe receptacle, arranged for reference; and cause alphabetical lists of persons and places to be made, kept, and opened for search.

It is to be observed that this act, which referred in its title to registers of births, made no provision for recording the date of birth. Neither did it provide a record of the date of death. It only provided records of the performance of the religious ceremonies of baptism, marriage, and burial, according to the rites of the Established Church. It therefore afforded an insufficient register, even for members of the Established Church; whilst for those who dissented from the Established Church, and therefore did not avail themselves of its ordinances for baptism or burial, it provided no register at all.

The inadequacy of this system, even if fully carried into effect, and the insufficient manner in which it was complied with, called loudly for investigation and remedy, and became the subject of inquiry before a select committee of the House of Commons, appointed in March 1833, who having, as they state, received evidence on registration "from clergymen of the Established Church, and from parish-clerks; from gentlemen of the legal profession; from authors devoted to antiquarian research; from persons of different religious denominations, including Catholics, Dissenters, Jews, and Quakers; from gentlemen eminently scientific, and attached to statistical inquiries; from medical authorities, who have long desired ampler and more accurate information on the extent and causes of mortality;

from an eminent foreigner, distinguished for extensive and accurate statistical intelligence; and others, whose wide-spread inquiries in foreign countries, and peculiar facilities of information, entitled them to respect," unanimously agreed to a report, which expressed the following opinions as the conclusions at which they had arrived:—

"1. That the subject is urgently important.

"2. That it involves matters of great public and national interest, as well as individual satisfaction, and rights and claims to property; and deserves the attention of the humblest artisan as well as of the most philosophical and statesman-like inquirer.

"3. That the existing law is imperfect and unjust, and requires not merely partial amendment, but real fundamental reform.

"4. That the present plan, even if improved and perfected, as applicable to the members of the Established Church, being founded on religious rights, is exclusive and intolerant, as it would not include a very considerable portion of the reflecting, intelligent, and influential population of the country, who are Protestant and Catholic dissenters from that church, and 1100 congregations who disapprove infant baptism, and must practically punish them (including, too, the community who may purchase or derive property from them) for claiming the rights of conscience, and believing what their judgments direct.

"5. That even to many pious and worthy clergymen of the Established Church the system is productive of pain and regret, as it often induces a compliance, from mere secular motives, with sacraments which they highly estimate and devoutly revere. But,

"6. That even as to the members of the church it is detrimental and absurd, since the registers are mere registers of baptisms and not of births, of burials and not of deaths; since they supply no adequate proof of pedigrees, or means of proving or tracing ancestral descent; since they are often falsified, stolen, burnt, inaccurately inscribed, and carelessly preserved; since the securities intended to be given by the last general register act (52 Geo. III.), by directing the yearly and universal transcription of the registers, their deposit with the diocesan records, and the preparation of indexes to facilitate searches, have all experienced only the most limited fulfilment, as, while one-fourth of the parishes make no returns, the returns that have been sent are never indorsed, and are subject to fire and decay, and the directions of the act have not and cannot be enforced; and since the value of property is diminished by the difficulties incident to its transfer, and the insecurity by which it is so often held and acquired. And,—

"7. That great trouble, vast expense, utter uncertainty, capricious charges, and local and general evils exist, while no means are supplied to obtain the information other countries possess, and justly value, as to the state of disease, the operation of moral and physical causes on the health of the people, the progress of population, and other matters on which accurate knowledge can scarcely be too highly appreciated or too intensely pursued."

The committee further recommended that, as a remedy for the defects before mentioned, "a national civil registration of births, marriages, and deaths should be established," including "all ranks of society, and religionists of every class."

In pursuance of these recommendations, measures for effecting a better registration were laid before Parliament; and in August 1836 the act for registering births, deaths, and marriages in England, and the act for marriages in England, became law. Their operation was suspended for a limited time by the act of 7 Will. IV., c. 1, and they were amended by the act of 1 Vict., c. 22, and thus amended they came into operation on the 1st of July 1837.

These acts leave untouched the act of 1812, so far as it relates to the registration of baptisms and burials, but repeal what relates to the registration of marriages, and provide a new registration of marriages, of *births*, and of *deaths*.

Existing registration of births, deaths, and marriages.

The circumstances recorded in the register-book under the existing law are, in case of *birth*, the time and place; the name, if any; sex; name and surname of father; name and maiden surname of mother; rank or profession of father; signature, description, and residence of the informant; and the baptismal name, if added after registration of birth. In case of *death*, the time and place; name and surname; sex; age; rank or profession; *cause of death;* signature, description, and residence of the informant. Every entry must be signed by the informant and by the registrar, who discharges this duty without any immediate expense to the parties requiring registration, but is remunerated by a moderate fee on each entry paid quarterly out of the poor-rates. The *informant*, in a case of *birth*, must be one of the parents, or the occupier of the house or tenement in which the child was born; or, if it be a foundling, the overseer of the poor. In a case of *death*, it must be some person present at the death, or in attendance during the last illness; or, in default of such person, the occupier, or, in default of the occupier, an inmate of the house in which the death occurred; or, if there be an inquest, the coroner. There is no legal obligation upon any one to give notice of a birth or a death to the registrar; the only obligation upon these parties is to give the required particulars, and to sign the register *on being requested so to do;* and without such signature no birth or death can be duly registered except in cases of inquest.

The form for registration of marriages, applicable alike to all religious denominations, records the place and time of marriage; names and surnames of the parties; whether they are of full age or minors; their civil condition (that is, whether bachelor or spinster, widower or widow); their rank or profession; residence at the time of marriage; father's name and surname; rank or profession of father; by what rites and ceremonies, after what preliminary forms (that is, whether license, banns, or certificate), and by whom solemnized; the entry must also contain the signatures of the parties and of two witnesses.

One of the most important circumstances not previously recorded, for which provision is made in the present register, is the "cause of death," to which a column is assigned in the registers of death, and where it is exhibited in juxtaposition with the period, locality, sex, age, and occupation, thus affording valuable data of the highest importance to medical science. In order to attain the utmost accuracy in the returns of the causes of death, the co-operation of medical practitioners in England and Wales has been invited, and the president of the Royal College of Physicians, the president of the Royal College of Surgeons, and the master of the Society of Apothecaries have recommended "that every practising member of any branch of the medical profession who may have been present at the death, or in attendance during the last illness of any person, shall, immediately after such death, place in the hands of such other persons as were in attendance, or of the occupier of the house in which the death occurred, or of some inmate who may probably be required to give information, a *written statement of the cause of death*, which such persons may show to the registrar, and give as their information on that subject."

In order that fatal diseases may be recorded in one uniform manner, the registrar-general furnishes all qualified medical practitioners, amounting to about 13,000, with books of printed forms of "certificates of cause of death," to be filled up and given to registrars of births and deaths; and he has circulated a nosological table of diseases for the purpose of securing, as far as possible, uniformity of nomenclature in the medical certificates.

General Register Office.

The registration system now in force is peculiarly distinguished from other previous measures on that subject, by the provision of a central office in London, called the General Register Office, for the deposit of certified copies of all registers, and general superintendence over everything relating to registration. This office, which is established at Somerset House, London, is presided over by an officer named the Registrar-General, appointed under the great seal, under whom are a chief clerk (who acts as secretary and assistant registrar-general), six superintendents, and a staff of clerks, who are appointed by the lords of the Treasury. Instructions emanate from the central office to all the local officers charged with the various duties of registration under this act, namely, superintendent registrars, registrars of births and deaths, and registrars of marriages, with their respective deputies, all of whom act within their several districts under the directions of the registrar-general, in whom is vested the power of dismissal.

Registrar-General.

The registrar-general is charged with the direction and superintendence of the entire system, every part of which is subject to his control and responsibility. He also executes various other duties under different acts of Parliament, in addition to those imposed upon him by the Registration Act. Among these may be mentioned the certifying of Nonconformist places of worship, the register of which he keeps; the execution of the provisions of the Compulsory Vaccination Act; the preservation and indexing of registers of marriages solemnized before British consuls abroad, and of marriages celebrated in India; the preparation of returns of mortality in towns, &c., under the Public Health Act; and the custody of the non-parochial registers authenticated by royal commissions in 1836 and 1857. He was also charged with the duty of taking the last decennial census (1851); and as the objects of that important work, and the machinery employed in accomplishing it, are analogous to the ordinary operations of the registration system, it may be presumed that the same course will be adopted on future occasions. The office of registrar-general was held by Thomas Henry Lister, Esq., author of a *Life of Clarendon*, and other literary productions, to June 1842, since which period it has been filled by George Graham, Esq.

Superintendent registrars.

The superintendent-registrar is a local officer created by the registration and marriage acts, acting solely within his district, which is usually identical with a poor-law union, in which case he is either the clerk of the guardians, who, as such, is entitled *ex officio* to take the office, or he is some person whom, the clerk not accepting, the guardians may have appointed, subject in either case to such qualifications as the registrar-general may by any general rule require.

The principal duty of this officer is to receive quarterly, from the registrars of births and deaths and registrars of marriages within his district, the certified copies of births, deaths, and marriages registered by them for the preceding quarter, and, having verified them by comparison with the original entries in the register-books, to certify their correctness, and transmit them to the registrar-general; to receive also and transmit, but not to verify, the certified copies of marriages registered by all clergymen of the Established Church within his district, or by any registering officer of the Quakers, or secretary of a Jewish synagogue, if there be any within or assigned to his district. He has also the care of the register office of his district, where are deposited all register-books within the district when filled; and he is to make indexes of these, and permit searches, and give copies of entries in the register-books, on payment of certain fixed fees. He may appoint registrars of marriage within his district; and the required previous notice having been given, he may grant certificates for marriage, and also licenses for marriage: the latter, however, can only be granted for marriage in a dissenting place of worship or in the district register-office. It is his duty to be present at marriages in the register-office, where no religious ceremony is permitted.

Registrars of births and deaths.

The registrar of births and deaths is a local officer, appointed in poor-law unions by the board of guardians. His duties are to register, in the books provided for that purpose, the births and deaths occurring within his sub-district; and four times in every year to make, on forms furnished for that purpose, copies of the entries, and to deliver them to the superintendent registrar of his district, who, on comparing them with the register-book, will certify their correctness, and transmit them to the registrar-general. He also delivers an account of the number of entries so copied, which the superintendent registrar verifies, if correct, to enable the registrar to obtain payment of the fees due thereupon from the guardians or overseers of the poor. Registrars of births and deaths are registrars of successful vaccinations, under the Act of 16 and 17 Vict., c. 100.

Registrars of marriages.

The registrar of marriages is a local officer appointed by the superintendent-registrar, and acts solely within his district, which is the same as that of the superintendent-registrar by whom he was appointed. His duty is to be present at and to register marriages not according to the forms of the Church of England, solemnized either in registered places of worship or in the district register office; and to deliver quarterly to the superintendent-registrar certified copies of such entries, in like manner as is done by the registrar of births and deaths.

Marriages, according to the forms of the Established Church, are registered by the officiating clergyman, who delivers certified copies quarterly to the superintendent-registrar of his district, to be transmitted to the registrar-general. The marriages are registered at the time *in duplicate;* and one of the books, when filled, is deposited in the district register office.

Marriages, according to the ceremonies of the Quakers and of the Jews, are registered respectively in duplicate by the registering officer of the Quakers and the secretary of the synagogue, and certified copies are given quarterly to the superintendent-registrar for transmission.

Number of registration officers, &c.

The number of persons by whom the registration of births, deaths, and marriages under the existing law is conducted (exclusive of the central establishment of the General Register Office) is as follows:—

There are 630 superintendent-registrars, each of whom may appoint a deputy, with the approval of the registrar-general, to act for him in case of his illness or absence. Of these, 586 have accepted the office as clerks of boards of guardians, or have been appointed by the guardians; and 44 are temporary, and have been appointed by the registrar-general.

There are 2197 registrars of births and deaths, each of whom may appoint a deputy, and of this number 2055 are appointed by the guardians established under the Poor-Law Amendment Act, and 142 are registrars of temporary districts, appointed by the Poor-Law Board.

The number of registrars of marriages on the 31st of December 1858 was 1250, each of whom may appoint a deputy; of these about one-half are also registrars of births and deaths. The number of other persons by whom registration of marriage is effected is as follows:—1*st*, 12,332 officiating ministers of the Established Church, to whom register-books have been furnished; 2*d*, 86 registering officers of Quakers; 3*d*, 47 secretaries of synagogues. All these are in communication with the registrar-general with respect to the duties of registration.

The 630 superintendent-registrars' districts, which are in general co-extensive with poor-law unions, vary greatly in population and extent. On an average, each district comprises three or four sub-districts, 26 parishes or places, 28,700 persons (census of 1851), and 59,800 statute acres. The 2197 sub-districts have each on an average 7 parishes or places, 8200 population, and 17,000 acres.

Registration districts.

Inspectors of registration.

Two inspectors are constantly employed in visiting every district into which England has been divided, for the purpose of instituting a searching inquiry as to the mode in which the responsible duties entrusted to the various registration officers are performed. The inspectors personally visit and instruct in each particular of their duties the registrars of births and deaths and of marriages, scrutinizing the register-books in use, and pointing out any erroneous practices they may discover; they likewise visit the district register-offices, and ascertain that the regulations issued for the guidance of superintendent-registrars are adhered to. At the end of each week the inspectors report to the registrar-general the result of their inquiries.

Deposit, arrangement, examination, and indexing of certified copies.

One of the most important features of the present system is the provision, that certified copies shall be deposited quarterly in the General Register Office in London, there to be arranged and indexed for facility of reference; a provision, by means of which a copy of an entry of any registered birth, death, or marriage, in any part of England or Wales, may be obtained by application at a single office, at the trifling cost of 3s. 6d., which includes the fee for search.

The certified copies thus transmitted from the clergy, registrars, registering officers, and secretaries (amounting together to more than 16,000 persons), are all made on separate leaves of durable paper, of an uniform size and peculiar texture, having a distinguishing water-mark for the prevention of forgery, and furnished by the registrar-general to every one of the foregoing persons, on whom the duty of registration devolves. They are sent by the superintendent-registrars by the post, each class of return (*i.e.*, birth, death, and marriage) being sent separate, and in a cover denoting by a mark the nature of the contents, and bearing the name of the district to which it belongs.

On their reception at the central office they are arranged and examined *seriatim*, and all defects are noted; and letters on the subject of such defects as are of any importance are addressed to the persons from whom the defective copies come, and who are required to furnish either other copies or such explanations as may remove doubt. The copies are then paged, and bound up in volumes for reference.

Means of immediate reference to any one of the entries of births, deaths, and marriages deposited in the General Register Office are provided in the alphabetical indexes which are made there. This vast work, far exceeding in magnitude anything of a similar kind ever before attempted in this country, is performed in the following manner:—The few particulars requisite for the index are copied from each entry *seriatim* on forms prepared for that purpose. These, after having been checked, are cut into separate slips, each containing the reference to one entry; and the slips are then sorted and arranged alphabetically on files, from whence they are then taken off one by one by the indexing clerks, and the contents of each copied into the index. In this manner about a million and a quarter of names are now indexed alphabetically in the course of each year, the processes of transcribing, sorting, and indexing being performed by nineteen persons, most of whom are paid by piece-work. After the lapse of a reasonable time for the completion of the arrangements referred to, the entry of any marriage, birth, or death which has been registered can generally, on the mere mention of the name, without intimation of the exact date or of the part of the kingdom in which it occurred, be very soon discovered, and a certified copy given; which copy, being stamped with the official seal, will be "received as evidence of the birth, death, or marriage to which the same relates, without any further or other proof of such entry." Thus not only are means afforded of obtaining for legal purposes, by application at one central office, certified copies of registers from every part of England and Wales, but the copies so obtained have the additional advantage of being sufficient evidence, without an affidavit, of their being correct, which is often required for the confirmation of extracts given from such registers.

Extent of the registration indexes.

The alphabetical indexes prepared in the General Register Office comprised, at the end of the year 1858, no less than 26,600,392 names,—viz., 6,083,906 of persons married, 12,209,383 of children born, and 8,307,103 of persons who died in the 20½ years from 1st July 1837, when the present law came into operation. The following table exhibits the yearly additions to the registers and indexes during this period:—

I. *Marriages, Births, and Deaths registered in England and Wales from July* 1, 1837, *to Dec.* 31, 1858.

Year.	Marriages.		Births.	Deaths.	Total of Names entered in the Registers and Indexes.
	Number.	Persons Married.			
1837*........	58,479	116,958	164,116	148,701	429,775
1838........	118,067	236,134	463,787	342,760	1,042.681
1839........	123,166	246,332	492,574	338,984	1,077,890

* Half-year from July 1, 1837, when operation of act commenced.

Facts relating to surnames deduced from the indexes.

From these extensive nominal lists of the immediate subjects of one or more of the events of birth, death, and marriage, many interesting facts have been derived with respect to the family or personal nomenclature of the people—a subject which has engaged the attention of antiquaries and others, who have discovered much that is illustrative of the early condition, customs, and employments of the inhabitants of this country in the names which have been handed down from bygone generations. A striking circumstance connected with this subject is the extraordinary number and variety of the surnames found to exist in England. The indexes of the births and deaths registered in a single quarter, after a careful elimination of all duplicates, were found to yield together 32,818 *different* surnames out of 275,405 entries; and from this result it is estimated that between 35,000 and 40,000 different surnames exist in England and Wales. This number is probably below the truth; at least, it is clear that by the introduction of the fresh names of foreigners and immigrants, and the corruption of existing names amongst the illiterate, the number is constantly increasing.

The acquisition of a particular surname was the result in most cases of arbitrary circumstances affecting the individual who first bore it; for instance, John *Smith*, instead of being called after his occupation, might equally have chanced to become John *Johnson*, from his father's Christian name; or John *Brown*, from his tawny complexion; or John *Hill*, from the local position of his abode. But the curious question arises, whether the surnames which have attained so remarkable a predominance over others owe this wholly to their original numerical importance, or whether any circumstances acting upon the ordinary laws of increase, have caused the descendants of their first possessors to multiply at a faster rate than the bearers of other names. The indexes have determined one point—namely, the surnames which have acquired the strongest hold on the people. The following list of 50 of the most common surnames—embracing 18 in every 100 persons registered—is derived from 25 quarterly indexes (9 of births, 8 of deaths, and 8 of marriages); and the probable number of persons in England and Wales of each surname is computed from the indexes of 1853:—

Common surnames.

II. *Fifty of the most common Surnames in England and Wales, and Estimated Number of Persons bearing each Surname in the Year* 1853.

Surnames.	Estimated Number of Persons of each Surname in 1853.	Of the entire Population, one in	Surnames.	Estimated Number of Persons of each Surname in 1853.	Of the entire Population, one in	Surnames.	Estimated Number of Persons of each Surname in 1853.	Of the entire Population, one in

16. Hall	60,400	305	33. Baker	43,600	422	50. Carter	33,400	551
17. Green	59,400	310	34. Morris	43,400	424	Total.........	3,253,800	5·7

Thus nearly one-sixth of the entries in the indexes relate to persons of these fifty surnames. The three at the head of the list, *Smith*, *Jones*, and *Williams*, are greatly in advance of the others; and so numerous are the great tribes bearing these names, that on an average one person in every 28 of the population would answer to one or other of them. *Smith* is pre-eminently the most common *English* surname, but that of *Jones*, from its frequency in Wales, not only competes for priority in point of numbers with the *Smiths*, but in several years contributes a larger number to the indexes. The following table exhibits—

III. *Number of Entries of the respective Surnames of Smith and Jones in the Registration Indexes*, 1838–54.

Year.	Entries in the Indexes of the Surname of		Difference.	
	Smith.	Jones.	More Smiths than Joneses.	More Joneses than Smiths.
1838...........	14,891	14,414	477	...
1839...........	14,905	15,096	...	191
1840...........	15,483	16,256	...	773
1841...........	15,237	15,539	...	302
1842...........	15,315	15,437	...	122
1843...........	15,841	15,554	287	...
1844...........	16,203	15,932	271	...
1845...........	16,633	16,676	...	43
1846...........	17,299	17,177	122	...
1847...........	16,917	17,296	...	379
1848...........	17,313	16,958	355	...
1849...........	18,091	17,677	414	...
1850...........	17,405	17,135	270	...
1851...........	18,156	17,525	631	...
1852...........	18,564	17,649	915	...
1853...........	18,775	17,926	849	...
1854...........	19,000	18,653	356	...
Total.........	286,037	282,900	4947	1810

The result of this tabular view of the relative frequency of these widely-spread surnames in the indexes of the years 1838–54, is an excess of 3137 *Smiths* in the seventeen years, but in six of the years the *Joneses* were more numerous than the *Smiths*; together, they furnish no less than 568,937 entries, or 1 in 36 of the whole number recorded. Thus it appears that, while *Smith* is the most generally diffused of English surnames, *Jones* is considerably superior to *Smith* in point of local distribution.

These large alphabetical lists of surnames have also determined the proportionate number occurring under each *initial letter*—a fact which may not be without interest to the philologist. The letter B is, it seems, the most frequent initial of surnames in England, comprising more than a tenth of the whole; next in number are the surnames ranked under the letter H (9·5 per cent.); then those under S and W (8·9 and 8·7 per cent.) The vowels are not of extensive occurrence as initial letters of surnames, although the contrary is the case with respect to the ordinary words of the English language. Other curious particulars, including a list of singular surnames met with in the indexes, will be found in the Sixteenth Annual Report of the Registrar-General.

Results of registration; vital statistics.

Although the primary object of registration is to furnish the means of establishing descent, and thereby to facilitate the legal distribution of property, it answers several other public purposes not less important. The expectations of those who predicted that from this system of observation and record materials would be derived of vast importance to the science of vital statistics have not been disappointed. No other country now possesses so extensive a collection of digested facts illustrative of the laws of mortality, the progress of population, and the influence of locality, occupation, seasons, and other physical causes upon the health of the people. The task of analysing the registered causes of death, and of collecting and arranging the important statistical materials deducible from the registers of births and marriages, as well as of deaths, has been committed to Dr William Farr.

Sanitary measures.

Before the results of the researches conducted by Dr Farr were published in the reports of the registrar-general, scarcely any attention was given to measures for the promotion of the public health. Dr Southwood Smith and others had indeed strongly urged the necessity for attending to the conditions essential to the preservation of health in towns, but it remained for the registration system to furnish the fundamental facts which led to a practical recognition of the importance of the question. The influences arrayed against sanitary legislation were powerful, and the general want of knowledge on the subject served to encourage the opposition with which it was assailed by vested interests. It was impossible, however, to disregard or controvert the facts and statistical calculations contained in the registrar-general's reports, in which it was shown that certain districts were infested with epidemics constantly recurring, while others enjoyed a comparative immunity; and that people suffered most in town districts where the causes of insalubrity operated with greater force than in other parts of the country. The excess of mortality in unhealthy districts, as compared with other localities, was unhesitatingly ascribed to artificial and preventible causes, producing "unnatural deaths" and inflicting material loss on the nation. With wealth, industry, and science at command, it was urged that means could be found to check the waste of life and health, and the evils resulting from men being cut off from their country and mankind before their time. In the year 1845 the first general enactment for enforcing measures of sanitary improvement passed the legislature; and by several subsequent acts extensive powers have been granted for the same purpose. Able and intelligent officers of health have been appointed in the metropolis, Liverpool, and most of the principal towns; extensive drainage works have been undertaken; and an improved water supply obtained. It cannot be doubted that these and other measures adopted to improve the public health are calculated to effect an amelioration in the physical condition of the inhabitants of this country.

Annual reports.

The annual reports of the registrar-general, of which nineteen have been laid before Parliament, form a valuable store-house of information upon the various subjects connected with vital statistics. Besides detailed abstracts for each year of the marriages, births, and deaths, tables of the fatal diseases, classified in combination with ages, are given, and comments upon the salient points of the year's registration accompany the whole. With regard to the marriages, a great number of statistical details are published, showing whether according or *not* according to the rites of the Established Church, the preliminary form (whether banns, license, or certificate), the civil condition of the parties, their ages, and whether they signed the marriage-register by writing their names or by making marks. The latter fact is not without interest, as throwing light upon the state of elementary education in England some fifteen years before; and it is grievous to find from this test that in the year 1857, of 100 men married, 28 could not write their names; of 100 women married, 39 signed with marks. No less than 30,518 marriages were celebrated in that year in which both the husband and the wife signed with marks; so that it may be inferred that an equal number of families would be founded in which neither the father nor the mother could read and write. In this respect, however, England cannot be unfavourably contrasted with France, for it is a curious fact that, exclusive of the metropolitan cities in the two countries, nearly the same proportion (34 in every 100) of the men who marry sign the register with marks; while the French women are even less versed in writing than English women, for of 100 women married, 55 in France, against 48 in England, did not write their names. These proportions, which are for the year 1853, are deplorably high, and show how much has to be done to convey the first rudiments of instruction to the great body of the people in two of the most enlightened nations of the world. In the abstract of births, those of children born out of wedlock are distinguished. All these particulars relating to marriages and births are given for each of the registration districts, counties, and divisions of England and Wales. The causes of death in each year are returned in detailed tables and discussed by Dr Farr, who has also, in occasional papers which have appeared in the reports, treated of the construction of life tables, the English life table and its uses, the principles of a statistical nosology, violent deaths in England, and many other subjects connected with vital statistics. These various practical applications of the facts shown in the abstracts are of great value and interest. An elaborate report on the cholera epidemic of 1849 has also been printed in a separate form.

From the annual reports of the registrar-general it appears that the mean annual rate of marriage in England is 8 *marriages*, or 16 *persons married*, to every 1000 persons living,—or one person in 61 of the population is married annually; there are 33 *births* to every 1000 persons living, or 1 birth in 30 of the population; and 22 *deaths* to 1000 persons living, or one death in 45 of the population. The marriage-rate was highest in the years 1845, 1846, 1850, and four following years, in all of which it exceeded 85 marriages to 1000 persons living; it was lowest in 1842 and 1843, when it fell below 76 per 1000. The birth-rate was highest (over 34 per 1000) in 1851, 1852, 1856, and 1857; and lowest in the earlier years of registration, when many births were unrecorded. Fluctuations in the death-rate are mainly influenced by epidemics, and by the varying temperatures of different years. In 1849 and 1854, years in which cholera greatly increased the mortality in this country, the rates were 25 and 23·5 per 1000; in 1847, when influenza prevailed epidemically, the rate was 24·7 per 1000. Amongst the healthiest years were 1845, 1850, and 1856, in each of which the rate of mortality was below 21 per 1000.

Quarterly and weekly reports.

About thirty days after the termination ot each quarter a return is published showing the number of births and deaths registered in the quarter in each of the 630 superintendent-registrars' districts in England and Wales, derived from statements sent to the central office by the 2197 registrars of births and deaths; the number of marriages is stated for the preceding three months. This return also comprises tables exhibiting the progress of population, emigration, the average prices of the funds and provisions, with meteorological observations taken at stations in different parts of the country under the supervision of Mr Glaisher; the whole is accompanied with remarks, in which the facts are generalized, and inferences drawn on points to which it is desirable that public attention should be directed. These quarterly reports have been continued since the year 1842; in the first instance, however, they referred only to the more populous districts, and not to the whole of England as at present.

Weekly reports.

Since the commencement of the year 1840 a report relating to London has been printed on the Tuesday in each week, compiled from returns received at the General Register Office on the preceding Monday. The metropolitan registrars who furnish these returns are 136 in number; they extract from the death register-books certain particulars respecting all the deaths registered in the week ending Saturday night, and state the total number of births registered. In this manner, early and accurate information is obtained with respect to the causes affecting the mortality of an aggregated town population, which amounted in 1851 to 2,362,236, the largest of which there is any reliable account. Remarks on the most noteworthy facts accompany the return, and the meteorology of the week, as observed at the Royal Observatory, Greenwich, is given. During the height of the cholera epidemics of 1849 and 1854 the registrars in London transmitted to the registrar-general *daily* returns of the deaths in their respective sub-districts.

Cost of registration.

The cost to the country of the registration system in force in England and Wales is now about L.100,000 a year, of which sum about L.65,000 are defrayed from the poor-rates for registrars' fees; and the remainder—consisting of L.18,000, for the central establishment, and L.17,000 for fees to superintendent-registrars and expenses of registration officers—is defrayed out of the public revenue. The portion of the expenditure paid from the national exchequer is annually voted by Parliament.

Defects of the system.

It is to be regretted that a machinery entailing so large an expense on the public is in some of its details marred by defects which render its operation unsatisfactory. In the first place, the registration of *births* is incomplete; for although the preamble of the act of William IV. sets forth the expediency of establishing and maintaining "a complete and uniform system of registration of births," &c., no obligation is imposed upon any one to give notice of a birth to the registrar. As a consequence of this laxity in the law many births pass altogether unrecorded, especially in large towns and amongst the poor. The registrar-general, in his Sixth Annual Report (1844), thus refers to the results of this omission in the act,—"At present I am well aware that many thousands of births annually escape registration; increased exertions on the part of the registrars may effect much; but in my opinion *all* the births will not be registered until by law it be made compulsory on the father or mother, or some other qualified informant, to give notice within a fixed period to the registrar of a birth having occurred, under a small penalty to be inflicted on default of giving such notice." This statement was made to the secretary of state nearly fifteen years ago, but no remedy has yet been applied, although under the provisions of the Compulsory Vaccination Act of 1854, the penalty for neglect of vaccination can only be enforced after due notice has been given by the registrar to the parents of the child on the registration of its birth. In order to make the first movement in the machinery of this statute universal, it is obvious that the penalty ought to be extended to the neglect of registering the birth.

The next defect of the English registration system is the absence of effectual precautionary measures against fabricated and fraudulent entries. Any person who has a sufficient motive for so doing has but to go to the house of the registrar and profess to give information of a birth or a death, and, by inventing consistent particulars, he may procure the insertion in the register of a purely fictitious entry, merely signing his name or making his mark as informant. In the memorable case of "Regina *v.* Barber, Fletcher, and others," a fraud to a considerable extent was effected on the Bank of England by means of a forged will, and a certified copy of a false entry of the pretended death of one Ann Slack. Besides the frauds committed by informants, several instances have occurred in which, for the sake of increasing their fees, registrars have fabricated entries on a very large scale; and similar frauds on a smaller scale may be carried on in town districts almost with impunity.

Obvious remedies.

After twenty years' experience of the working of the present system, the application of a remedy to these defects could not be a very difficult matter. Some additional checks are obviously required for the prevention of fictitious and fraudulent entries. If, in the case of births, the register were attested by another witness besides the informant, such as the accoucheur or mid-wife, or some other person assisting at the birth,—and, in the case of deaths, the register were to contain an authenticated statement of the fact of *burial* as well as of the *cause of death*, inserted from the certificates of authorized parties,—these guarantees would interpose great difficulties in the way of frauds. A compulsory enactment, making it incumbent on all who are present at a birth or a death, and the occupier of the house in which it takes place, to give notice of the fact to the registrar, would ensure *complete* resignation. The schedules are also susceptible of considerable improvement. The following schedules, compiled by a committee of the Statistical Society of London from the schedules of other states in which registration is practised, are given as models; the information provided for in the English schedules is indicated by the words printed in *italics*:—

Schedule A.—Marriages.

COUNTY, *Middlesex*; DISTRICT, *Marylebone*.—1847. Marriages solemnized at *the Parish Church*, in the Parish of *Marylebone*.

No.	When, where, and how Married.	Names and Signatures of the Parties.	Residence.		Age.	Rank or Profession.	Condition.			Birth-place.	Parents.		Witnesses and Officiating Minister.
			Present.	Usual.			If a Widower or Widow, date of decease of former Wives or Husbands.	Children by each former Marriage. Living.	Children by each former Marriage. Dead.		Name.	Rank or Profession.	
124	On *March* 3, 1847, at *Marylebone Parish Church.* Marriage, after *banns*, was solemnized between us according to the rites and ceremonies of the Established Church.	*William Hastings.*	3 *South Street, Marylebone.*	Chelmsford, Essex.	32	*Carpenter.*	*Widower*, 4th Nov. 1840.	2	1	Bristol.	*Peter Hastings*, deceased, and Ann Hastings (maiden name, Payne).	*Upholsterer.*	*John Hastings, Jane Mitchell*, witnesses. *James Hollingshead, Curate*, officiating minister.
		Sophia Ann Mitchell.	17 *High Street, Marylebone.*	17 High Street, Marylebone.	20	*Dressmaker.*	*Spinster.*			Longbridge, Deverell, Wilts.	*Geoffrey Mitchell*, and Sarah Mitchell (maiden name, Evans), deceased.	*Butcher.*	

Schedule B.—Births.

COUNTY, *Middlesex*; DISTRICT, *St Pancras*; SUB-DISTRICT, *Tottenham Court.*

CHILD.					PARENTS.			INFORMANTS.	WITNESSES.	
					Father.		Mother.			
No.	Name, and whether produced or not.	Sex.	When Born: Year—day—hour.	Where born: If in lodgings, so stated.	Name, Rank or Profession, Age, Birthplace.	When and where married. Issue, living and deceased.	Name, Maiden Name, Rank or Profession, Age, Birthplace.	Signatures of Father and Mother, and other Informants, and where residing, if out of the house in which the Birth occurred.	Accoucheur, Nurse, by whom certified, and Signatures of Occupier or other Witnesses.	When, where, and by whom Registered.
98	*William Jones* (produced); *alteration of name, if any, and date thereof.*	*Male.*	1847. *February eleventh,* 5h. 30m. A.M.	169 *Tottenham Court Road.*	*Henry Jones, corn-dealer,* 40, Tingewick, Bucks.	1830, St Pancras. 2 boys, 2 girls, living; 1 girl dead.	*Harriet Jones, maiden name Hills* (her 5th child), 37 St Pancras.	*Henry Jones,* father; *Harriet Jones,* mother.	Ann Curry, nurse, witness. Certified by M. Clayton, accoucheur.	1847, *March* 10, at 169 Tottenham Court Road; *John Wells, Registrar.*

Schedule C.—Deaths.

COUNTY, *Middlesex*; DISTRICT, *Poplar*; SUB-DISTRICT, *Poplar.*

No.	(1.) Name.—(2.) Rank or Profession.	Sex.	Age.	(1.) When and (2.) where died, year—day—hour.	(1.) Cause of Death, and Duration of Disease.—(2.) Medical Attendant by whom Certified; when he last saw Deceased.	(1.) Burial-Place.—(2.) Undertaker by whom Certified.	Where born, and how long in this District.	(1.) Parents' Names, and (2.) Rank or Profession.	If Deceased was Married,		Signatures of (1.) Informant, (2.) Witness, and (3.) Registrar; (4.) Date of Registration.
									Where, at what age, and by whom.	Issue, in order of Birth, their Names and Ages.	
176	*William Canty, dock-labourer.*	*Male*	62	1847, *February twenty-eight, at* 16 *Cottage Row.* 6½h. A.M.	*Pneumonia,* 2 *months,* as certified by H. Bloomfield, M.D., who last saw deceased Feb. 27th.	Catholic burial-ground, Wade Street, as certified by M. Rutley, undertaker.	County of Cork, Ireland; 36 years in Poplar.	Timothy Canty, shoemaker, deceased; Mary Canty (m. n. Nicolas), deceased.	Scrill parish, Ireland, at age 22, to Honora M'Carty.	1, Timothy, 31—2, William, 30—3, Mary, 29—4, John, dec. at 27 in 1846—5, Catherine, 21.	*Honora Canty, widow,* informant; Mary Canty, daughter, witness; *T. W. Gagen, registrar, March third,* 1847.

In order to determine whether any practical difficulties would be found in eliciting for registration the various facts required in these schedules, experiments were made in several parts of London, and it was found that all the information was furnished without objection by the parties applied to; and the committee of the Statistical Society considered that no insuperable difficulties existed in the way of carrying out such a plan on a national scale.

Parochial registers.

It is stated in the preface to the Population Abstract for 1831, as the result of an inquiry respecting parochial registers in England, "that eight hundred and twelve English parish registers commence in the year 1538, about forty of which contain entries (copied probably from family Bibles and tomb-stones), anterior to the date of Cromwell's injunction; 1822 parish registers commence from A.D. 1538 to 1558, when Queen Elizabeth required a protestation from the clergy; 2448 parish registers commence from A.D. 1558 to 1603, when the canons authorized by King James directed a copy of all extant parish registers to be made and preserved; and nearly one-half of them (5082) have been preserved accordingly, and are now extant. Parish registers to the number of 969 commence between that time to the year 1650; 2757 from A.D. 1650 to 1700; 1476 parish registers from A.D. 1700 to the year 1750; the rest (six or seven hundred) since that time.

Non-parochial registers.

In addition to the registers heretofore and now kept under the sanction of ordinances and acts of Parliament, there is a vast number of non-parochial registers and records of marriages, births and baptisms, deaths or burials, which have been kept in some instances from a very remote period by various dissenting congregations, and in many cases with great care and correctness, but in no form prescribed by authority and under no legal sanction, and which were therefore not admitted in evidence as registers in courts of justice.

In September 1836 a commission was issued, directing certain commissioners to inquire into the state, custody, and authenticity of such registers or records; "and to inquire whether any or what measures could be beneficially adopted for collecting and arranging all or any of such registers or records, and for depositing the same, or copies thereof in the office of the registrar-general of births, deaths, and marriages, or for otherwise preserving the same; and also to consider and advise the proper measures to be adopted for giving full force and effect in evidence, in all courts of justice, to all such registers as might be found accurate and faithful, and for facilitating the production and reception of the same." From the report of the commissioners of the result of their labours, it appears that about 7000 non-parochial registers were transmitted to them for inspection, from 3630 religious congregations, namely,—

Foreign Protestant churches	37
Presbyterians, Independents, and Baptists	2264
Wesleyan Methodists	818
Moravians	10
Lady Huntingdon's Connection	44
Calvinistic Methodists	436
Swedenborgians	21
Total	3630

"Each of these registers," says the Report, "was authenticated by a certificate under the signature of the minister, or of some officer of the church or denomination, from whom it was received; and this certificate was generally accompanied by answers to the questions which had been circulated by the commissioners." After being "classed in lists according to the several counties in England and

Wales, and entered in a book, with a careful annotation of any particulars applicable to their state or custody," they were "submitted to the inspection of the board, by whom the question as to their admissibility was discussed and recorded; and in every instance the chairman, or the commissioner representing the chairman, authenticated such inspection and examination, by affixing his initials to the first and last entry in each register; or if some parts of the register appeared to be copies, or not to bear marks of authenticity, he affixes his initials to such parts only as were deemed original or authentic." With respect to all such registers as were thus examined and deemed authentic, wholly or in part, the commissioners recommended "that they be kept together in some secure place of deposit, under the care of the registrar-general, or some other officer to be appointed for that purpose, that, under certain conditions, they be receivable in evidence in all courts of justice;" and that the authorized custos of these registers should permit searches, and grant certified extracts, on payment of moderate fees.

These several recommendations were embodied in an act of Parliament, passed in 1840, "for enabling courts of justice to admit non-parochial registers as evidence of births or baptisms, deaths or burials, and marriages" (3 and 4 Vict., c. 92); and, pursuant to its provisions, the registers have been placed in the custody of the registrar-general, by whom searches are permitted, and certified copies granted. The Society of Friends having discovered in different parts of the country a considerable number of registers which had been overlooked when the others were collected, were naturally anxious to secure an extension to them of benefits similar to those conferred by the act above cited; and to afford the Society, and other religious communities who might be in possession of registers under similar circumstances, an opportunity to effect this object, a second royal commission was issued in 1857 for the purpose of verifying the registers. The general course of proceeding adopted by this commission was the same as on the former occasion, and 303 register-books were, after examination and inquiry, reported upon as fit to be received into the custody of the registrar-general. By an act which passed in 1858, these additional registers were placed on the same footing as the other non-parochial records.

Registration in Scotland.

The institution of parish registers in SCOTLAND dates from the year 1551, when, amongst other new canons enacted by the provincial council of Scottish clergy held at Edinburgh, was one establishing parochial registers of baptisms and proclamations of marriage. In this canon no provision was made for any record of burials, but the deficiency was afterwards supplied during the early struggles of the Reformation. In 1616 an act of the Scottish Privy Council ordained that in every parish a book should be kept in which the minister should insert "the tymes and names of the persones to be maryed, and of the bairnes to be baptized, within the said parrochine, with the witnesses of the saidis bairnes, as alswa the names and tymes of personis deceisand within the same;" and the minister or reader, along with two of the kirk-session, in the case of births and marriages, and two persons present at the burial, in the case of deaths, were to subscribe the register-book at the close of the entries of each day. The *Directory for Public Worship*, which was approved by an act of the General Assembly, and also by a statute of the Scottish Parliament in 1645, soon after the re-establishment of Presbyterianism, declares that a register for marriages shall be carefully kept, but contains no similar injunction regarding baptisms and burials. In the year 1746 the General Assembly appears to have found it necessary to pass an act to provide for the registration of *burials*. The records of the church contain no other provisions respecting registration until the year 1816, when the defective state of the parochial registers engaged the attention of the General Assembly, which recommended that the several presbyteries should take the steps necessary to secure the keeping of three separate registers in each parish: one for births, whether the parents of the children belonged to the church or were dissenters; another for marriages, whether legally solemnized or not; and a third for deaths and burials.

Ecclesiastical injunctions having failed to remedy the manifold defects of the system of parochial registration, Lord Rutherford, who then filled the office of Lord Advocate, in the year 1847 brought into Parliament two bills, by one of which it was proposed to alter the law concerning marriages, while the object of the other was to secure the compulsory registration of births, deaths, and marriages. These two bills passed the Upper House, and were read a second time in the House of Commons in the same session, and again in 1848, when they were finally abandoned by the government. With a more successful result, a bill was prepared and introduced into Parliament by Lord Elcho, M.P., one of the lords of the Treasury, to whose persevering efforts his country is indebted for the valuable measure which passed the legislature in 1854, "for the better registration of births, deaths, and marriages in Scotland" (17 and 18 Vict., c. 80).

The provisions of this act—which are in some degree analogous to those of the English acts, but with the necessary adaptations of machinery to the peculiarities of Scottish institutions, and some important improvements—came into full operation on 1st January 1855. A "General Registry Office" is established at Edinburgh, the business of which is conducted by a registrar-general (the deputy for the time being of the lord clerk register) and a secretary, besides clerks and other officers; and local registrars are appointed to act in every parish and burgh. The appointment of registrar in parishes not being burghal is vested in the parochial board; in burghs it is vested in the town-council. The control and superintendence of the registrars within each county devolves upon the sheriff, by whom they may be removed on the application of the parochial board or the registrar-general. It is the duty of the registrar to inform himself of every birth and death within his parish, and to register the same *in duplicate*. In order to assist informants, the registrar is to furnish *gratis* printed forms, setting forth the heads of the particulars required to be recorded. An important provision, the absence of which is one of the defects in the English law, secures the complete registration of births. Within twenty-one days after the occurrence of any birth, the parents or parent, or (in case of their death or inability) the person in charge of the child born, the occupier of the house, and the nurse, are required, under a penalty not exceeding 20s. in case of failure, to *attend personally* upon the registrar, and give information of the particulars of the birth. So also, in the case of deaths, the *nearest relatives present* at the death, and the occupier of the house in which it occurred—and if the occupier should be deceased, then his or her nearest relatives, and the *inmates* of such house—are bound, under a penalty not exceeding 20s. in case of failure, to *attend personally* upon the registrar, and give information concerning the particulars required to be registered. In both cases, one of the parties attending to give information is required to sign the register in duplicate in the presence of the registrar. After the expiry of three months, no birth can be recorded without the authority of the sheriff, by whom also the entry must be signed. In cases of doubt, parents may be required, under a penalty for refusal, to *produce the child* to the registrar.

The genuineness of the registry of death is supported by two important corroborative documents. Within fourteen days after the death, the medical attendant is required, under a penalty not exceeding 40s. in case of failure, to transmit to the registrar a certificate in the form prescribed; and within three days after the interment, the undertaker, under a like penalty for default, is to transmit to the registrar a certificate thereof. The particulars of these certificates are forthwith inserted in the registers.

The Scottish law of marriage and the proclamation of banns are nowise affected by the Registration Act; regular marriages are registered upon the receipt of the proper schedule, duly signed, from the contracting parties, or by the registrar on his attending for that purpose at the solemnization of the marriage. Due provision is made for the registry of irregular marriages.

All registers are required to be kept in duplicate; and after they have been examined, compared, and *docqueted* by the district examiner, one of the duplicates is retained by the registrar, and the other is transmitted to the registrar-general. At the General Registry Office alphabetical indexes of the duplicate registers there deposited are prepared, and any person is entitled to search the indexes on payment of the fee of 1s., and to have an extract of any entry under the hand of the registrar-general, on the payment of the further fee of 2s. *Gratis* searches may be permitted, and *gratis* extracts given to persons of whose inability to pay the registrar-general shall be satisfied.

The following are the numbers of births, deaths, and marriages, registered in Scotland, in each of the four complete years during which the present system has been in operation:—

Marriages, Births, and Deaths registered in Scotland 1855–58.

Year.	Marriages.		Births.	Deaths.
	Number.	Persons Married.		
1855...........	19,690	39,380	93,599	62,249
1856...........	20,487	40,974	101,748	58.456
1857...........	21,314	42,628	103.628	61,925
1858...........	19,603	39,206	104,195	63,532

Of the 104,195 births in the year 1858, 9256 were illegitimate. This gives the proportion of one illegitimate in every eleven births, or 9 per cent.; a proportion much higher than that shown by the English registers, which, however, are incomplete. In Scotland the ratio of births to population rather exceeds that in England; while the ratio of marriages is greatly inferior to it: the mean mortality in Scotland is below that of England.

The annual reports hitherto published consist merely of general abstracts of the numbers of registered births, deaths, and marriages, which the registrar-general is required to transmit to the secretary of state, to be laid before Parliament; the figures are given for Scotland, and for each of the divisions and counties, without comment. A quarterly return is prepared, showing each quarter's registration more in detail, the numbers for the several parishes or districts, as well as for counties and divisions, being given; and a monthly report is made for Glasgow, Edinburgh, and six other principal towns, comprising, in addition to other particulars respecting the results of registration, classified lists of the causes of death at four periods of age.

The schedules annexed to the Registration Act, according to which the registers were to be made, were framed with a view to obtain more comprehensive information than that provided for by the English schedule, and the additional facts to be ascertained on registering a birth, death, or marriage were of importance both for the better identification of the parties, and for the purposes of statistical inquiry. It is to be regretted, however, that under the powers given by the act to the registrar-general to alter the schedules, some of the additional heads of information have been omitted in the register books now in use, the alteration having been made after a very short trial of the schedules annexed to the act.

Registration in Ireland.

The want of a complete measure of registration for Ireland has on various occasions been the subject of representations in Parliament and elsewhere. In the year 1844 an act was passed for the registration of marriages in Ireland (7 and 8 Vict., c. 81); but that statute is obviously imperfect as a measure of registration since the marriages of Roman Catholics, who form the majority of the population, are excluded from its provisions. Such exclusion arose from the fact of certain formalities being required by the statute to be observed in the case of every marriage falling within its purview, the omission of which formalities might be held to render a marriage invalid; and these restrictions in the case of their marriages were considered objectionable by Roman Catholics. The registration under this act commenced on 1st April 1845; the total number of marriages registered in the nine years 1846–54 inclusive, was 83,085, giving an average of 9228 marriages annually, or about 1 marriage for every 710 of the population. In England, during the same nine years, the marriages were in the ratio of 1 to every 119 persons; so that, taking the marriages of the Irish people in the same ratio, an annual average of 55,062 marriages, instead of 9228, would have been recorded under a complete system. There is in Ireland no provision for the registration of births and deaths, the duties of the registrar-general and the district registrars being confined to marriages. A bill to provide for a general system of registration has been prepared by the chief secretary for Ireland, Lord Naas, M.P.; and it may reasonably be hoped that Ireland will not long be pointed at as the only civilized country in Europe, whether Roman Catholic or Protestant, in which there is no registry of births, deaths, and marriages.

Registration in France.

The registration of births, deaths, and marriages in France is conducted under the provisions of the *Code Civil* of Napoleon. The *maire* of each *commune*, of which there are about 37,300 in France, is the registering officer charged with the duty of registering, in books provided for the purpose, all births, deaths, and marriages occurring within his commune. Births and deaths are registered in duplicate, the former upon information, in the presence of two witnesses, and are signed in duplicate by the informant, the two witnesses, and the registering officer; in the case of deaths, one of the witnesses may be also the informant. Marriages are registered in the presence of four witnesses, and signed by the parties, the witnesses, and the registering officer. The register of births records the year, day, hour, and place of birth; the sex and name of the child; the name, surnames, professions, and residences of the parents, witnesses, and informant; the date of registration, and the name and quality of the registering officer; and must be signed by him, by the witnesses, and by the informant. When the child is illegitimate, the name of the father cannot be given except by the authority of the father himself.

The register of deaths records the year, day, hour, and place of death; the name, surname, age, profession, and residence of the deceased person; the names, surnames, ages, professions, and residences of the parents of the deceased, and of the witnesses; and the name and surname of the husband or wife, if the deceased was married; also the date of registration, and the name and quality of the registering officer.

The register of marriages records the names, surnames, ages, professions, places of birth, and residences of the parties; the names, surnames, professions, and residences of their respective parents, and of the four witnesses, with the relation in which they stand to the parties; the consent of the parents; whether the marriage has been opposed; time and place of solemnization and registration; and the name and quality of the registering officer.

Registration of births is secured by a provision which requires, under pain of fine and imprisonment, from the father of the child, or, in default of the father, from some person present and assisting at the birth, a declaration thereof, within three days afterwards, to the registering officer, to whom the child must also be shown.

The registration of deaths is secured by a provision rendering it penal for a burial to take place without the registering officer having first seen the body and registered the death.

The registers are closed at the end of every year, with formalities which preclude interpolation. Alphabetical indexes are annually formed in duplicate for each. One of the duplicate registers, with its index, remains in the commune to which it belongs; the other is transmitted to the tribunal of the district, where it is examined and placed under the superintendence of the *procureur du roi*, or the local officer of the crown. Abstracts are made by the registering officer of each commune, a copy of which is transmitted to the sub-prefect, who from thence frames an abstract for his arrondissement, a copy of which he sends to the prefect; he also from the abstracts of the arrondissement makes an abstract for his department; and copies of such abstracts are sent by the prefects of departments to be deposited in a central office at Paris.

The system of registration observed in France was introduced into Belgium, Geneva, and the Rhenish provinces of Prussia when under the dominion of France, and is still retained in those countries.

Registration in Austria.

In Austria, registers of births, deaths, and marriages are kept by each minister of the church for his parish, and also by the Jewish rabbin for those of their own persuasion.

The register of births records the year, month, and day of birth; the number of the house in which the birth occurred; the name of the child and its sex, and whether it be born in wedlock or illegitimate; the names and surnames of the parents; their religion; and the names and surnames and condition of the sponsors. In the case of illegitimate children the name of the father cannot be entered unless he acknowledges the paternity.

The register of deaths records the year, month, and day of death; the number of the house in which it occurred; the name, religion, sex, and stated age of the deceased; and, when the information of a physician or surgeon can be supplied, the name of the fatal disease. For this purpose, medical men are required to inform the minister, in writing, of the cause of death of such patients as they have attended.

The register of marriages records the year, month, and day of the marriage; the place of solemnization; the names and surnames of the parties; their religion, age, and whether single or widowed; and the names, surnames, and condition of the witnesses.

Bishops, on every visitation of their dioceses, are obliged to call for the production of the registers of births, deaths, and marriages. The provincial authorities are also required to ascertain whether these registers are kept in all places as prescribed by law.

Annual abstracts must be made by the ministers and the rabbin, of which copies must be sent to the district of the conscriptions, and to the office of the circle.

Registration in Prussia.

In Prussia, except the Rhenish provinces, registration is committed to the clergyman of the parish amongst Christians, and the elders amongst Jews. The clergyman is bound to enter the births, marriages, and deaths, of persons who are not of the Established Church, but who are "simply tolerated," on the declaration of the parties or their ministers, and to include these declarations in his annual returns. Duplicates of the registers are to be made, and at the end of each year deposited, when examined and verified, in the local civil court, being "the tribunal of the place."

(*Report by the Select Committee on Parochial Registration*, 1833; *History of Parish Registers in England*, by J. S. Burn, 1829; *Population Abstract for* 1831; *Report of the Commissioners appointed to inquire into the State, Custody, and Authenticity of Non-Parochial Registers*, 1838; Registrar-General's *Reports*, 1838 to 1858; *Letters on the Law of Registration*, by Horace Mann, barrister, 1849: *Manuel des Officiers de l'Etat Civil pour la tenue des Registres*, par A. E. le Mott, Paris, 1827; *Sketch of the History of the Parochial Records in Scotland*, by Geo. Seton, advocate, 1854. (J. T. H.)

REGISTRATION OF DEEDS. The 2d and 3d Anne, c. 4, provided for the public registry of all deeds, conveyances, and wills relating to any manors, lands, tenements, or hereditaments within the West Riding of the Riding and Kingston-upon-Hull by the 6th Anne, c. 35, county of *York*. This statute was extended to the East and to the North Riding by 8 Geo. II., c. 16. The act of 7 Anne, c. 20, provided for the registry of deeds, conveyances, wills, and other incumbrances on lands, &c., in the county of *Middlesex*. The effect of the register acts is to render prior unregistered deeds fraudulent and void, as to all subsequent deeds whereof memorials have been duly registered; so that a purchaser or mortgagee can only be affected by a deed duly registered, of which he may have notice by examining the register. The registration should be made immediately after the execution of the conveyance, otherwise the delay might enable another encumbrancer to take priority. Before Lord Campbell's abolition of Arrest Act, 1 and 2 Vict., c. 110, judgments of the superior courts constituted a charge on real estates, and searches had to be made for twenty years in the several courts to ascertain whether any such charges existed. By that act the remedies of creditors was extended over the property of their debtors; but it was enacted that no judgment or decree should affect any real estate otherwise than before the act, until registered with the senior master of the Common Pleas at Westminster. And the 2d and 3d Vict., c. 11, and the 3d and 4th Vict., c. 82, provided that these judgments should be renewed every five years, or be of no effect. But as against purchasers or mortgagees, *without notice*, such judgments or decrees should not bind any lands or tenements, although registered, otherwise than a judgment of the superior courts would have bound such purchaser or mortgagee before the act of the 1st and 2d Vict., c. 110.

If the purchaser or mortgagee has notice of a judgment against the vendor, the judgment creditor will take priority, but the purchaser or mortgagee is not required to search for judgments, though it is usual for solicitors, by way of precaution, to do so; and if there is an entry of a judgment within five years, the vendor will be required to remove the charge before he can call for a completion of the purchase. In the first session of Parliament of 1859 a bill passed the House of Lords to provide that no *bonâ fide* purchaser or mortgagee should be bound by any other than actual notice of any charge affecting the title to the property. It was also proposed in the House of Commons to establish a Landed Estates Court, in which the title to real property might be investigated (as in Ireland); and on due notice to all parties interested, and on satisfactory proof, the court might grant an indefeasible title; and by another bill it was proposed that such title might then be entered in a public registry, and all future dealings with the property so registered should be entered on the register of titles. These bills, on the dissolution of Parliament in April 1859, were postponed.

The system of registration in Scotland appears to secure the utmost safety that can be attained in transactions affecting heritable property. Wherever such property passes out of the hands of any individual, either voluntarily or by the act of the law, it is made the interest of the party to whom it is transferred to warn the public of the fact, by the insertion of certain instruments in a public register. If he delay to do so, it is at his own risk; for in all competitions for the property it is the date, not of the voluntary or judicial act, but of its publication in the appropriate register, which determines the preferable right. If a person wish to become the purchaser of any heritable property situated in a Scotch burgh, he may examine the burgh register, and if he find the right of the property standing unencumbered in the person with whom he proposes to transact, and find no legal interpellation in certain other registers, he may transact with perfect safety, provided he take care to publish his having done so in the burgh register immediately. The like arrangement follows in regard to heritable properties in counties, for which there are what is called the particular record for each county, and the general record applicable to them all. Thus an intending purchaser can always ascertain whether any prior disposition, or heritable bond or other burden, or adjudication by the law or other legal impediment, exist, which can prevent him in good faith from purchasing with safety. Some or all of these things may be actually in existence; but if they be not published in the manner now referred to, and if the purchaser took the precaution to have his own title timeously published, they can only affect the seller personally (who is punishable for granting double dispositions) and his heirs, but the purchaser's title is the preferable one. There is a strong feeling in England against the exposure of domestic and private arrangements by such registers; but that is now satisfactorily avoided in Scotland, where, by recent improvements, the fact of the real right having passed from one person to another may be published in the shortest possible way; though, wherever burdens on property are meant to be created, these burdens must fully and distinctly appear on the record, otherwise they will not affect third parties transacting in ignorance. The statutes regulating these matters in Scotland are the acts of the Scotch Parliaments, 1698, c. 4; 1693, c. 15 & 35; 1696, c. 5 & 39; also 8 & 9 Vict., c. 31 & 35; 10 & 11 Vict., c. 48 & 50; 17 & 18 Vict., c. 62.

REGNAULT. See DISSERTATION SIXTH, § 632.

REGULUS, MARCUS ATILIUS, a Roman consul, who is celebrated by ancient poets and historians for his self-sacrificing heroism during the first Punic war, about 260 B.C.

REHER, a town and district of Hindustan, in the province of Delhi. The town has much declined, in consequence of the seat of government having been removed to Nijibabad. It is 80 miles N.N.W. from Bareily; Long. 104. 35. E., Lat. 57. N. The district is situated between the twenty-eighth and twenty-ninth degrees of north latitude. It formerly constituted the northern limit of Kuttaher or Rohilcund, and was ceded to the British by the Nabob of Oude in the year 1801. Both town and district are now included in the collectorship of Bareily.

REICHENAU, a town of Bohemia, in the circle and 9 miles E.S.E. of Königgrätz. It has an old and a new princely palace, the latter one of the finest buildings of Bohemia, with a valuable library and picture gallery; a Piarist college, gymnasium, and another school; manufactures of linen and woollen cloth, and an important market for corn. Pop. 4500.

REICHA, ANTON, an excellent composer and didactic writer on musical composition, was born at Prague on 27th February 1770. Having learned singing and the elements of music, he left Prague in his seventeenth year to join his uncle, Joseph Reicha, an eminent violoncellist and good composer, who was settled at Bonn, in the service of the Elector of Cologne, and who completed the musical education of Anton. Some of Anton Reicha's biographers assert that he studied music under Mozart and Michael Haydn. In 1794 Anton Reicha went to Hamburg, and remained there for five years as a teacher of the piano and of accompaniment. There he composed the music of a French opera, which he was advised to bring out at Paris. Arriving at Paris in 1799, he produced a successful symphony at the Rue de Cléry concerts; but owing to the closing of the Feydeau and Favart theatres, was disappointed in bringing out an opera. He then went to Vienna, where he held friendly intercourse with Haydn, Albrechtsberger, Salieri, and Beethoven. He now devoted himself to composition, and produced a great number of various works. Among these were *Trente-six Fugues pour le Piano, d'après un Nouveau Système*, dedicated to Haydn. There was nothing new in this system, it having been suggested to Reicha by a bad treatise on fugue published by the French writer H. F. M. Langlé, and founded on a false system of responses to fugue subjects on every degree of the scale, and the destruction of all distinct tonalities. Reicha's work was published in 1803, but met with no success, although some writers were so ignorant of the truth as to call Reicha "the restorer of the fugue." About the close of 1808 Reicha sought refuge in Paris from the evils of a new war in Germany. In Paris he began to teach musical composition according to an expeditious method, which consisted in directing the attention of his pupils solely to the forms of modern music, to the exclusion of all those forms which it is necessary to study in order to obtain a real knowledge of the art of composition. In 1814 he published his *Traité de Mélodie*, in which he claims the merit of being the first to write upon that subject,—thereby proving his complete ignorance of the various excellent works on melody published by Italians and Germans, and even of the work on composition published by the Frenchman Momigny in 1806. There are good things in Reicha's work, although he takes too narrow a view of his subject under the aspect of rhythm and melodic phrases only, neglecting altogether the laws of melody as these relate to tonality, modulation, harmony, and beauty. In 1817 he succeeded Méhul as professor of counterpoint in the Paris conservatory; and in 1818 published his *Cours de Composition Musicale*,—a work founded upon wrong views of the theory of chords, but containing much useful practical information. In 1824 and 1826 he published his *Traité de Haute Composition Musicale*, in which his ignorance of historical facts, and of the forms of ancient music, were so great as to bring him under the severe criticisms of the Abate Baini, in the latter's work on Palestrina. Reicha treats of double counterpoint as applicable to modern composition, but takes no notice of simple counterpoint, which is really the foundation of all other kinds.

While settled in Paris Reicha enjoyed the friendship and counsel of Cherubini. Very desirous to obtain success as a dramatic composer, he produced three operas,—*Cagliostro*, which fell flat on the first representation; *Natalie* in 1816, and *Sapho* in 1822, both unsuccessful. Several times he sought to be admitted as a member of the French Academy of Fine Arts, but was denied that honour until after the death of Boieldieu in October 1835, whose place he then obtained. He died at Paris, of inflammation of the chest, on 23d May 1836, and was buried on the 30th in the cemetery of Père Lachaise. His funeral obsequies were performed in the church of St Roch, and were attended by Cherubini, Paër, Auber, and all the members of the Institute, as well as the professors and pupils of the Conservatory, and the artists of the Royal Academy of Music and of the Comic Opera. He bore the rank of Knight of the Legion of Honour, and was highly esteemed in private life by his numerous friends. Besides the works already mentioned, Reicha published many others. His best compositions are his twenty-four Quintets for flute, oboe, clarinet, horn, and bassoon, which are much esteemed by connoisseurs. Three of his didactic works are *Etudes ou Théories pour le Pianoforté*, 1800; *Art du Compositeur Drama-*

Reichenbach.

tique, 1833; *Petit Traité d'Harmonie Pratique à Deux Parties.* His other works are numerous, consisting of two Symphonies, an Overture, an Octuor, Quintets for various instruments, twenty stringed Quartets, Trios, Duets, Sonatas for piano and violin, Sonatas for piano, Studies and Fugues for the piano, Variations, &c. (G. F. G.)

REICHENBACH, a town of Saxony, in the circle and 7 miles S.E. of Zwickau. It is, next to Plauen, the largest manufacturing and commercial town in this part of the country; upwards of 500 of the inhabitants being employed in the manufacture of cloth, especially merino and cashmere. Weaving, spinning, and dyeing are also carried on here. A great part of the town was destroyed by a fire in 1833. Böttiger the antiquary was born here in 1760. Pop. 9127.

REICHENBACH, a town of Prussia, in the province of Silesia, circle and 31 miles S.W. of Breslau, on the Pielbach, and near the Eulengebirge. It is surrounded by a double moat and walls; and has a castle, several churches and schools, a town-hall, &c. Manufactures of woollen cloth are carried on here; and there is some trade. Pop. 5760.

Reichenberg.

REICHENBERG, a town of Bohemia, second in size and importance to Prague, in the circle of Bunzlau, on the Neisse, an affluent of the Oder, 58 miles N.E. of Prague. It has many good buildings, but the streets are narrow, uneven, and irregular. There are here two palaces (one of which once belonged to Wallenstein), a Piarist college, several schools, and a theatre. The principal manufactures of the town are those of linen, cotton, and woollen stuffs, the dyeing of silk, tanning, the making of gloves and hosiery, jewellery, and musical instruments. Pop. 13,184.
